Draft Supplemental Environmental Impact Statement (D-SEIS) for the proposed U.S. Army Corps of Engineers Ala Wai Canal Flood Risk Management Project; Island of O'ahu, Honolulu District; Multiple Tax Map Keys (TMK) in Zone 2, Sections 3-4 and Sections 6-9

The City and County of Honolulu hereby submits a Draft Supplemental Environmental Impact Statement (D-SEIS) on behalf of the U.S. Army Corp of Engineers Ala Wai Canal Flood Risk Management Project located in the Honolulu District of the island of O'ahu (multiple tax map keys (TMKs) within Zone 2, Sections 3-4 and Sections 6-9).

We request this Draft Supplemental Environmental Impact Statement be published in the next available issue of The Environmental Notice, thereby initiating the public-comment period during which the public may submit comments to the City and County of Honolulu.

If there are any questions, please contact us at 808-768-8480.

Sincerely,

Action summary

This Tentatively Selected Plan (TSP) would involve the construction of floodwalls at Woodlawn Bridge along the Mānoa Stream, at the confluence of the Mānoa and Pālolo Streams, along the Mānoa-Pālolo Canal, and along the Ala Wai Canal, as well as a detention basin at the Ala Wai Golf Course. This tentatively selected alternative also includes structure elevation and floodproofing of 70 structures to mitigate for induced flooding. The purpose of the tentatively selected plan is to reduce flood risk within the Ala Wai Watershed given that a high level of flood risk exists within the Ala Wai Watershed due to extensive urban development throughout the watershed, coupled with the watershed's unique topography and hydrology (i.e., steep mountainous terrain and propensity for intense rainfall events within the headwaters).

Honolulu, Hawaii 96813

November 2023

Ala Wai Canal General Reevaluation Report and Integrated Supplemental Environmental Impact Statement, Oahu, Hawaii

Document Type:	Draft General Reevaluation Report with Integrated Supplement Environmental Impact Statement
Responsible Agencies (Project Sponsors):	City and County of Honolulu U.S. Army Corps of Engineers
Study Authority:	Section 209 of the Flood Control Act of 1962 (Public Law 87-874)
Location:	Ala Wai Watershed, City and County of Honolulu; Oahu, Hawaii
Tax Map Key(s):	Various TMKs in Zone 2, Sections 3-4 and Sections 6-9.
Actions Requiring HRS Chapter 343 Review:	Use of State or County lands or the use of state or county funds and use within the Waikiki area of Oahu.
Determination:	The USACE and the City and County of Honolulu have determined that the proposed action requires the preparation of a supplemental EIS, based on the requirements of NEPA and Chapter 343.
Notes:	The City and County of Honolulu is the proposing agency for purposes of complying with Hawaii Revised Statutes (HRS) Chapter 343; the accepting authority would be the Governor of Hawaii. The USACE is the lead agency for purposes of complying with the National Environmental Policy Act (NEPA).

Abstract

This Draft General Reevaluation Report with Integrated Supplemental Environmental Impact Statement (Draft GRR/SEIS) has been prepared for the Ala Wai Canal Flood Risk Management Study, Oahu, Hawaii. The purpose of the Ala Wai Canal Flood Risk Management Study is to reduce riverine flood risks in the Ala Wai Watershed. The study is authorized by Section 209 of the Flood Control Act of 1962 (Public Law 87-874), which is a general study authority for surveys in harbors and rivers in Hawaii "with a view to determining the advisability of improvements in the interest of navigation, flood control, hydroelectric power development, and other beneficial water uses, and related land resources." Section 209 does not authorize the implementation of the proposed action.

Flooding associated with a 1% annual exceedance probability (AEP) rainfall event would affect approximately 3,111 structures with an estimated $905,327,000 in structural damages alone (2023 price levels). In response to identified flood-related problems and opportunities, a series of flood risk management measures were identified and formulated into four alternatives, including the No Action alternative. The alternatives were evaluated through an iterative screening and reformulation process, resulting in the tentative selection of a plan for implementation. The tentatively selected plan would reduce flood risks by constructing one detention basin and concrete floodwalls averaging 6 feet high along Woodlawn Drive, Koali Road, and Kaimuki High School. In addition, concrete floodwalls averaging 6 feet high would be constructed on both sides of the Manoa-Palolo and Ala Wai canals. Potential adverse impacts include those related to biological resources, cultural resources, recreation, and aesthetic/visual resources; however, measures to avoid, minimize, and mitigate these impacts have been incorporated to the extent practicable. Although some degree of impact would occur, project analyses have not identified significant, unavoidable adverse impacts that would remain after implementation of proposed mitigation measures. The tentatively selected plan is the national economic development plan.

The City and County of Honolulu is the non-federal cost-sharing sponsor for all features. Based on October 2023 price levels, the estimated first costs of the TSP, including application of nonstructural mitigation measures for induced flooding, is $1.075 billion. The cost share apportionment is 65% Federal and 35% non-federal, therefore, the federal portion of the estimated first cost is $698,472,000 and the non-federal sponsor portion is $376,101,000. The non-Federal sponsor would provide all lands, easements, rights-of-way, relocations, and suitable borrow and disposal areas and would also assume responsibility for operation, maintenance, repair, replacement and rehabilitation (OMRR&R). The estimated average annual OMRR&R cost is $359,000. The non-Federal sponsor will continue to participate in and comply with applicable Federal floodplain management and flood insurance programs.

This Draft GRR/SEIS is being made available for public review beginning November 24, 2023. The official closing date for the receipt of comments is January 8, 2024, 45 days from the date on which the notice of availability of this Draft GRR/SEIS appears in the Federal Register and The Environmental Review. Comments may be mailed to the address listed below. Comments may also be emailed to the email address listed below.

Executive Summary

ES.1 Introduction

This Draft General Reevaluation Report (GRR) with a Supplemental Environmental Impact Statement (SEIS), subsequently referred to as "Draft GRR/SEIS", has been prepared for the Ala Wai Canal General Reevaluation Study, located on the Island of Oahu, Hawaii. It assesses the risk of flooding in the Ala Wai Watershed and describes a range of potential alternative plans formulated to reduce flood risk, with identification of a tentatively selected plan. It constitutes both a Draft GRR, in accordance with the U.S. Army Corps of Engineers (USACE) planning process, and a Draft Supplemental Environmental Impact Statement (SEIS), as required to comply with both the National Environmental Policy Act (NEPA) and Hawaii Revised Statutes (HRS) Chapter 343. Following public and governmental agency review, the Draft GRR/EIS is finalized and submitted to Headquarters USACE, the Assistant Secretary of the Army for Civil Works (ASA(CW)), and the Office of Management and Budget (OMB) for review and approval. If approved, a Chief of Engineers Report would be sent to Congress recommending authorization of the recommended plan described in the Final GRR/SEIS.

ES.2 Purpose and Need

The purpose of this study is to identify and select a tentative plan that will reduce flood risk within the Ala Wai Watershed given that a high level of flood risk exists within the Ala Wai Watershed. Extensive urban development throughout the watershed, coupled with the basin's unique topography and hydrology (i.e., steep mountainous terrain and propensity for intense rainfall events within the headwaters) result in elevated flood risk for a large proportion of the population both along the Ala Wai Canal and within the Makiki, Manoa, and Palolo valleys. Flooding has occurred within the watershed on multiple occasions, resulting in recorded property damages and health and safety risks. Analyses conducted in support of this study show that the 1% annual exceedance probability (AEP) flood event—an event with a 1% chance of being equaled or exceeded in any given year—affects approximately 3,111 structures with an estimated $905,327,000 in structural damages alone (2023 price levels), not accounting for loss in business income or other similar economic losses. A map of the potential extent of inundation resulting from the 1% AEP flood event is illustrated in Figure ES-1. The Ala Wai watershed has approximately 200,000 residents. The watershed also contains the University of Hawai'i and the Waikiki District—a prime tourist destination that attracts more than 79,000 visitors per day and accounts for approximately 8% of the gross state product and 11% of all civilian jobs in the state. This Draft GRR/EIS analyzes a series of alternatives designed to reduce the on-going flood risks throughout the Ala Wai watershed, including a no action plan, as well as various combinations of structural, non-structural, and natural and nature-based measures.

Figure ES-1: USACE Inundation Map of 1% AEP Flood Event

ES.3 Plan Formulation

The USACE's planning process is based on the *Economic and Environmental Principles and Guidelines for Water and Related Land Resources Implementation Studies* promulgated in 1983 (U.S. Water Resources Council 1983). The Principles and Guidelines provide for development of reasonable plans that are responsive to Federal, state, and local concerns. A total of 224 management measures—or actions that can be taken to meet the planning objectives throughout the watershed—were identified by the USACE study team or brought forth by members of the public during public workshops held during the current Ala Wai Canal General Reevaluation Study or the previous feasibility study. All 224 management measures were evaluated and either retained or screened from further consideration prior to alternative formulation. A total of 30 management measures were retained and incorporated into the formulation of alternative plans.

A cornerstone approach to plan formulation was used. The cornerstone approach utilizes a single measure as the starting point for formulating an alternative plan. Subsequently, additional

measures are added which complement the cornerstone measure, and the additional measures are intended to increase both the effectiveness and efficiency of the alternative plan. Formulation of the alternative plan stops once no further measures can be incorporated into the alternative plan which make it more effective and efficient. A total of 9 alternatives were included in the initial array of alternative plans, including a no action plan (Alternative 0) and plans designed to store of floodwaters (Alternative 1), improve conveyance of floodwaters through use of existing infrastructure (Alternative 2A), floodwalls (Alternative 2B), and a 2nd canal outlet (Alternative 2C), diverting floodwaters from the upstream tributaries to the ocean through tunnels (Alternative 3), using natural and nature-based solutions to modify the watershed, (Alternative 4), increasing both storage and conveyance of floodwaters (Alternative 5), and reducing the consequences of flooding through application of nonstructural measures (Alternative 6). Plans included in the initial array were evaluated and reformulated to maximize their efficiency and effectiveness and determine whether they would move forward into the final array of alternatives.

The final array of alternatives consisted of the no action plan (Alternative 0), the storage alternative (Alternative 1), the floodwall conveyance alternative (Alternative 2B), the storage and conveyance hybrid alternative (Alternative 5), and the nonstructural plan (Alternative 6).

ES.4 Tentatively Selected Plan (TSP)

The USACE planning process requires detailed economic analyses (and associated refinements) to ensure that an alternative plan being considered for selection is economically justified, such that no other variation of that plan could be more economically beneficial (i.e., no other variation could better maximize the national economic development (NED) account). Specifically, these analyses include incremental justification (to ensure that each measure included in the alternative is economically justified) and optimization (to ensure that the scale of each measure maximizes benefits). In the case of this project, it was determined that the alternative plans in the final array provided a reasonable basis for evaluation and comparison, and that detailed economic analyses and refinements should only be performed for the higher-ranking alternative identified through the evaluation and comparison process. It was determined that similar analysis and refinements were not needed for the other action alternative in the final array, as they would not affect the relative comparison between the alternatives. Based on this approach, additional detailed economic analyses and design refinements were conducted for Alternative 5. Various increments and refinements were considered (with additional alternative number modifiers added accordingly), leading to identification of Alternative 5.3 as the NED plan. Alternative 5.3 includes floodwalls at Woodlawn Drive along the Manoa Stream, at the confluence of the Manoa and Palolo streams, along the Manoa-Palolo Canal, and along the Ala Wai Canal, as well as a detention basin at the Ala Wai Golf Course. Alternative 5.3 also includes structure elevation and floodproofing of 70 structures to mitigate for induced flooding. Federal policy requires that the NED plan be recommended for implementation unless there are overriding reasons for recommending another plan. The attributes of the NED plan were reviewed relative to the planning objectives, criteria, and engineering standards, and it was determined that there were no overriding reasons that warranted recommendation of another plan, such that the NED Plan was identified as the recommended plan. Alternative 5.3 is also the plan that reasonably maximizes benefits comprehensively in accordance with the established evaluation criteria.

ES.5 Performance of the TSP

The TSP maximizes benefits within the NED, regional economic development (RED), and other social effects (OSE) accounts, having the greatest net economic benefits, regional economic benefits (i.e., labor income and jobs supported), maximizing reductions in life safety risk, and maximizing benefits to socially vulnerable communities and populations. The TSP is the most equitable in terms of flood risk reduction by ensuring socially vulnerable communities experiencing recurring and frequent flooding receive comparable flood risk reduction opportunities as more affluent communities in the watershed.

The TSP will have only minor environmental impacts and is an acceptable plan from an environmental standpoint. Specifically, the recommended plan will not have significant impacts on the environment under the NEPA and will have no effect on federally listed species or designated critical habitat under the ESA. The TSP can be implemented in compliance with all applicable environmental laws and regulations.

ES.6 Costs and Benefits

The estimated first costs of the TSP associated with the structural features are $775 million, and the average annual cost is $29.8 million at an FY23 2.5% discount rate. The average annual costs of nonstructural mitigation are an additional $10.6 million, resulting in a total average annual cost of $40.4 million at an FY23 2.5% discount rate. Average annual net benefits for the TSP with and without the nonstructural mitigation measures are $17.9 million and $22.5 million, respectively. The benefit cost ratio (BCR) for the TSP with and without nonstructural mitigation measures is 1.8 and 1.4, respectively, at an FY23 discount rate of 2.5%.

ES.7 Cost Sharing

The City and County of Honolulu is the non-federal cost-sharing sponsor for all features. Based on October 2023 price levels, the estimated first costs of the TSP, including application of nonstructural mitigation measures for induced flooding, are $1.075 billion. The cost share apportionment is 65% Federal and 35% non-federal, therefore, the federal portion of the estimated first cost is $698,472,000 and the non-federal sponsor portion is $376,101,000. The non-Federal sponsor would provide all lands, easements, rights-of-way, relocations, and suitable borrow and disposal areas and would also assume responsibility for operation, maintenance, repair, replacement and rehabilitation (OMRR&R). The estimated average annual OMRR&R cost is $359,000. The non-federal sponsor will continue to participate in and comply with applicable federal floodplain management and flood insurance programs.

ES.8 Environmental Impacts and Environmental Commitments

The TSP is the proposed action. The TSP is made up of measures, also referred to as project features, to minimize the extent of flooding within the Ala Wai watershed during frequent storm events.

The project footprint encompasses the physical location of the proposed action and all included measures, either individually or collectively, which includes the Ala Wai Canal and Manoa-Palolo Canal and portions of adjacent uplands along these areas as well as upland areas along Manoa Stream (Woodlawn Drive floodwall) and the Manoa and Palolo streams (Koali Road floodwall) that will be impacted to facilitate construction associated with the TSP shown in Figure 31: Conceptual Diagram of Alternative 5.3.

Action area includes the project footprint and areas outside of the the project footprint where indirect impacts from construction or implementation of the TSP could occur as well as the

marine aquatic habitat in the Ala Wai Small Boat Harbor and the marine aquatic habitat within 1,640 feet (500 meters) of the mouth of the Ala Wai Small Boat Harbor.

For less frequent storm events such as the 0.2% AEP flood event—an event with a .2% chance of being equaled or exceeded in any given year—project features induce flooding for some properties that do not already experience floodingunder the existing condition. Therefore, mitigation measures would be implemented to minimize the impacts of induced flooding from the proposed project. Potential nonstructural mitigation measures that could be applied include dry/wet floodproofing, elevation, and acquisition. In addition to nonstructural mitigation measures, it is possible that additional analyses during the pre-engineering and design (PED) phase could identify structural mitigation measures not currently included in the TSP, such as pump station(s), as being required to mitigate induced flooding.

Preliminary analyses undertaken during the development of alternative plans indicate expected technical challenges and inefficiencies associated with utilizing pumps for reducing induced flooding. Therefore, the current mitigation analysis excludes pump stations and focuses on potential application of nonstructural measures. Additional analysis would be conducted during PED to determine the precise number and location of structures recommended for dry/wet floodproofing, elevation, or acquisition, as well as to reconsider other structural mitigation measures, as appropriate. Supplemental NEPA analysis and coordination would be conducted in subsequent phases of the project, as appropriate, to ensure proper consideration is given to required mitigation actions.

Construction of the project would take approximately four years. All construction activities would comply with the City of Honolulu noise ordinance established by the State of Hawaii Department of Health (Noise Section). However, the use of certain pieces of construction equipment required for the project would create substantially increased levels of noise and vibration temporarily. To minimize these impacts, USACE would obtain an approved community noise permit from the City of Honolulu. In addition the following environmental commitments would be implemented to further minimize short-term adverse effects to noise and vibration levels within the action area: 1) use of appropriate level of sound attenuation during construction to meet local ordinances; 2) provide residents and businesses near the project footprint advance notice of project activities, schedule, anticipated traffic, and potential noise issues; 3) space apart haul trucks operating near sensitive receptors to avoid noise effects from simultaneous operation; 4) prohibit use of engineer brake (jake brake) within city limits; and 5) have the contractor properly maintain and tune engines of all equipment and maintain properly functioning mufflers on all internal combustion engines to minimize noise levels.

The proposed project is not expected to have direct adverse impacts on federally listed species; however, the project could have indirect adverse impacts. Therefore, to minimize potential adverse impacts to federally threatened and endangered species the following environmental measures would be implemented to 1) avoid and minimize potential project impacts to Hawaiian hoary bat, 2) avoid and minimize potential project impacts to Hawaiian seabirds, 3) avoid and minimize potential project impacts to Hawaiian waterbirds, and 4) avoid and minimize potential project impacts to green sea turtle, hawksbill sea turtle, and Hawaiian monk seal. For details regarding the avoidance and minimization measures briefly listed above refer to Section 3.4 of the main IFR/EIS.

Based on the studies conducted to date, it was determined that construction and operation of the proposed project could impact historic properties within the Direct Area of Potential Effect

(APE). Potential impacts include modifications that may affect the integrity and/or characteristic of historic properties. The following environmental commitments would be implemented to minimize adverse impacts to cultural resources: 1) historic buildings, bridges, and walls affected by construction would undergo appropriate historic documentation, and design input would be solicited from State Historic and Preservation Office (SHPO) and interested consulting parties and incorporated into the final design where feasible; 2) design input to minimize visual impacts to the greatest extent possible will be solicited from SHPO and interested consulting parties, and incorporated as feasible, into the final design and construction of floodwalls; 3) if previously unknown cultural resources are discovered, work in the immediate area would cease until the requirements in 36 CFR 800.13 are complied with; and 4) design input to further minimize visual impacts to the greatest extent possible will be solicited from SHPO and interested consulting parties, and incorporated as feasible, into the final design and construction of the floodwalls around the Ala Wai Canal. For additional details on the above environmental commitments refer to Section 3.5.1 of the main IFR/SEIS.

The proposed project includes mitigation measures for induced flooding as a result of project features. The implementation of nonstructural mitigation measures, primarily elevation of residential structures, would have potentially adverse impacts on land use and planning. Therefore, the following environmental commitments would be implemented to minimize adverse impacts to land use and planning: 1) phase construction to ensure there is adequate temporary housing available due to scarcity of housing in the area, and 2) simultaneously implement nonstructural measures for whole blocks or streets of residences so that construction windows within neighborhoods can be minimized.

The proposed project includes floodwalls that range in height from six to nine feet. This would result in the floodwalls becoming permanent landscape features. The floodwalls would typically be dominant and often only somewhat compatible to the action area being a coastal landscape commonly holding panoramic views of water. The floodwalls, being an enclosure by design, would often block views and become a dominant feature in a now enclosed landscape. Therefore, the floodwalls are characterized as only somewhat compatible because in many places they disrupt the current harmony with the coastal landform, causing the broad and open experience currently available to be lost. Therefore, the following environmental commitment being implemented for adverse impacts to cultural resources, would also be implemented for adverse impacts to visual and aesthetic resources: design input to further minimize visual impacts to the greatest extent possible will be solicited from SHPO and interested consulting parties, and incorporated as feasible, into the final design and construction of the floodwalls around the Ala Wai Canal.

During construction of the proposed project there would be potential significant adverse impacts to traffic and transportation due to the presence of construction vehicles. Specific impacts that could occur are: increased traffic congestion and/or reduce circulation when hauling trucks are present; increased degradation of existing pavement/condition of roadways from heavy construction vehicles and equipment; decreased driver safety because of reduced sight-distance or increased visual hazards associated with construction vehicles; temporary changes in access to businesses, residences, or public facilities; and temporary reduction in availability of public on-street parking. To reduce significant adverse impacts during construction to less than significant the following environmental commitment would be implemented: require the construction contractor to prepare and implement a Transportation Management Plan. For additional details on measures to be included in a Transportation Management Plan refer to Section 3.5.8.

Soil classes present in the project footprint range from soils least susceptible to seismic amplification (i.e.,least susceptible to liquefaction) to soils most susceptible to seismic amplification. (i.e., most susceptible to liquefaction). To minimize potential impacts to proposed project features, design of the proposed project would follow seismic design requirements which would provide structural stability and would further reduce potential adverse impacts.

All other resource categories not listed above would experience either no impacts, negligible, or minor adverse impacts that would not require the implementation of environmental commitments. Best management practices would be implemented, however, to minimize negligible and minor adverse impacts as feasible.

ES.9 Plan Implementation

The implementation plan is still being developed by the project delivery team. The non-Federal sponsor supports this project.

ES.10 Views of the Public, Agencies, Stakeholders, and Tribes

A significant number of stakeholder and agency meetings and other public involvement efforts have been conducted throughout the planning process to-date. In general, the timing and focus of these events has been determined in response to project-related needs and stakeholder interests and desires. A wide range of input has been provided as part of the various public and agency meetings held to date. In general, stakeholders have expressed support for the project and emphasized the need for near-term action to reduce the risk of flooding. Concerns have been raised relative to the non-federal sponsor's ability to fund and maintain the project, as well as potential impacts of the project (particularly those associated with visual, cultural and recreational resources), and acquisition of private property.

ES.11 Reviews

No documented reviews have been conducted. The first technical District Quality Control (DQC) review will begin on October 02, 2023.

ES.12 Areas of Known or Expected Controversy

NEPA requires identification of issues of known controversy that have been raised in the scoping process and throughout the development of the study. The following issues were identified as a result of public scoping, stakeholder engagement, and environmental review.

Impacts to Cultural and Aesthetic Resources: Waikiki is a scenic tourist destination with a high concentration of historic and cultural resources. The construction of six-to-nine-foot floodwalls would change views of the water from land and conversely of the cityscape from the water. The assessment of effects and potential mitigation measures will continue into the PED phase.

Opportunity for Nature Based Solutions: Public input and agency input has conveyed a preference for natural and nature-based features (NNBF) or green solutions to address flooding as opposed or in addition to traditional structural solutions. Some nature-based features were identified as feasible; however, none could be shown to reasonably reduce riverine flooding.

Property Acquisition: In some cases, permanent property acquisition would potentially be needed due to induced flooding from project features. Efforts have been made to minimize the need for acquisition. Temporary construction easements would be required for construction staging and equipment access. Temporary restrictions on access to private property may also be necessary. Flowage easements would also be required in some areas. Specific property

acquisition requirements have not been identified at this time.

Chapter 1: Introduction

5.6 Introduction

The Ala Wai Watershed is located on the southeastern side of the island of Oahu, Hawaii, and includes Makiki, Manoa, and Palolo streams, all of which drain to the Ala Wai Canal. The Canal is a 2-mile-long waterway constructed during the 1920s to drain extensive coastal wetlands, thus allowing development of the Waikiki District. A large portion of the watershed, including most of Waikiki, is highly susceptible to flooding.

This Draft General Reevaluation Report (GRR) with a Supplemental Environmental Impact Statement (SEIS), subsequently referred to as "Draft GRR/SEIS", has been prepared for the Ala Wai Canal Flood Risk Management Study, Oahu, Hawaii. This current study is also referred to as the Ala Wai Canal General Reevaluation Study. It assesses the risk of flooding in the Ala Wai Watershed and describes a range of potential alternative plans formulated to reduce flood risk, with identification of a tentatively selected plan. This document constitutes both a Draft GRR, in accordance with the U.S. Army Corps of Engineers (USACE) planning process, and a Draft Supplemental Environmental Impact Statement (SEIS), as required to comply with both the National Environmental Policy Act (NEPA) and Hawaii Revised Statutes (HRS) Chapter 343. Following public and governmental agency review, the Draft GRR/EIS is finalized and submitted to Headquarters USACE, the Assistant Secretary of the Army for Civil Works (ASA(CW)), and the Office of Management and Budget (OMB) for review and approval. If approved, a Chief of Engineers Report would be sent to Congress recommending authorization of the recommended plan described in the Final GRR/SEIS.

This Draft GRR/SEIS was prepared by USACE in close coordination with the City and County of Honolulu—the non-federal sponsor for the Ala Wai Canal General Reevaluation Study. The Ala Wai Canal General Reevaluation Study represents a congressionally authorized opportunity to reevaluate the outcome of the Ala Wai Canal Flood Risk Management Study, O'ahu, Hawaii, which was completed in 2017. Additional information on the history of this effort is provided below in Section 1.5.

1.2 USACE Planning Process

In February (Walsh 2012a) and March (Walsh 2012b) 2012, two planning memoranda were issued that collectively revised USACE's approach to planning studies and emphasized risk-based decision-making and early vertical team, commonly known as leadership chain, engagement during the study. The new process is called Specific, Measurable, Attainable, Risk Informed, and Timely (SMART) Planning, and is derived from the Principles and Guidelines and the USACE Planning Guidance Notebook (Engineering Regulation (E.R.) 1105-2-200). With SMART Planning, a study still works progressively through the six-step planning process, including: 1- identification of the problems and opportunities related to flood risk management; 2- inventorying and forecasting existing and expected conditions; 3- formulating alternative flood risk management plans; 4- evaluating the effects of each alternative plan; 5- comparing the alternative plans to one another; and 6- identifying a tentatively selected plan. This Draft GRR/SEIS uses this six-step planning process as a roadmap for description of the overall study process.

1.3 Study Authority

The Ala Wai Canal General Reevaluation Study was authorized by Section 209 of the Flood Control Act of 1962 (Public Law 87-874) and Section 216 of the Flood Control Act of 1970 (Public Law 91-611), as amended. Section 209 is a general study authority that authorizes surveys of harbors and rivers in Hawaii. The applicable portion of Section 209 states:

> "The Secretary of the Army is hereby authorized and directed to cause surveys for flood control and allied purposes including channel and major drainage improvements, and floods aggravated by or due to wind or tidal effects, to be made under the direction of the Chief of Engineers, in drainage areas of the United States and its territorial possessions, which include the following named localities: *Provided*, That after the regular or formal reports made on any survey are submitted to Congress, no supplemental or additional report or estimate shall be made unless authorized by law except that the Secretary of the Army may cause a review of any examination or survey to be made and a report submitted to Congress, if such review is required by the national defense or by changed physical or economic conditions: *Provided further*, That the Government shall not be deemed to have entered upon any project for the improvement of any waterway or harbor mentioned in this title until the project for the proposed work shall have been adopted by law: Harbors and rivers in Hawaii, with a view to determining the advisability of improvements in the interest of navigation, flood control, hydroelectric power development, water supply and other beneficial water uses, and related land resources."

This study was appropriated under the Supplemental Appropriations of the Bipartisan Budget Act of 2018 (Public Law 115-123), dated 9 February 2018, which funded initiation and/or completion of previously authorized flood and storm damage reduction studies.

1.4 Study Area

The Ala Wai Watershed is located on the southeastern side of the island of Oahu, Hawaii. The watershed encompasses 19 square miles (12,064 acres) and extends from the ridge of the Ko'olau Mountains to the nearshore waters of Mamala Bay (Figure 1). It includes the Makiki, Manoa, and Palolo streams, which flow to the Ala Wai Canal, a 2-mile-long, man-made waterway constructed during the 1920s to drain extensive coastal wetlands. The construction and subsequent draining allowed the development of the Waikiki District.

The study area is the Ala Wai watershed, shown in Figure 1. The study area is comprised of 14 damage reaches, the delineation of each being informed by the hydrology and hydraulics of the watershed and intended to group structures appropriately for modeling and benefit evaluation. Figure 2 displays a map of the study area's 14 damage reaches.

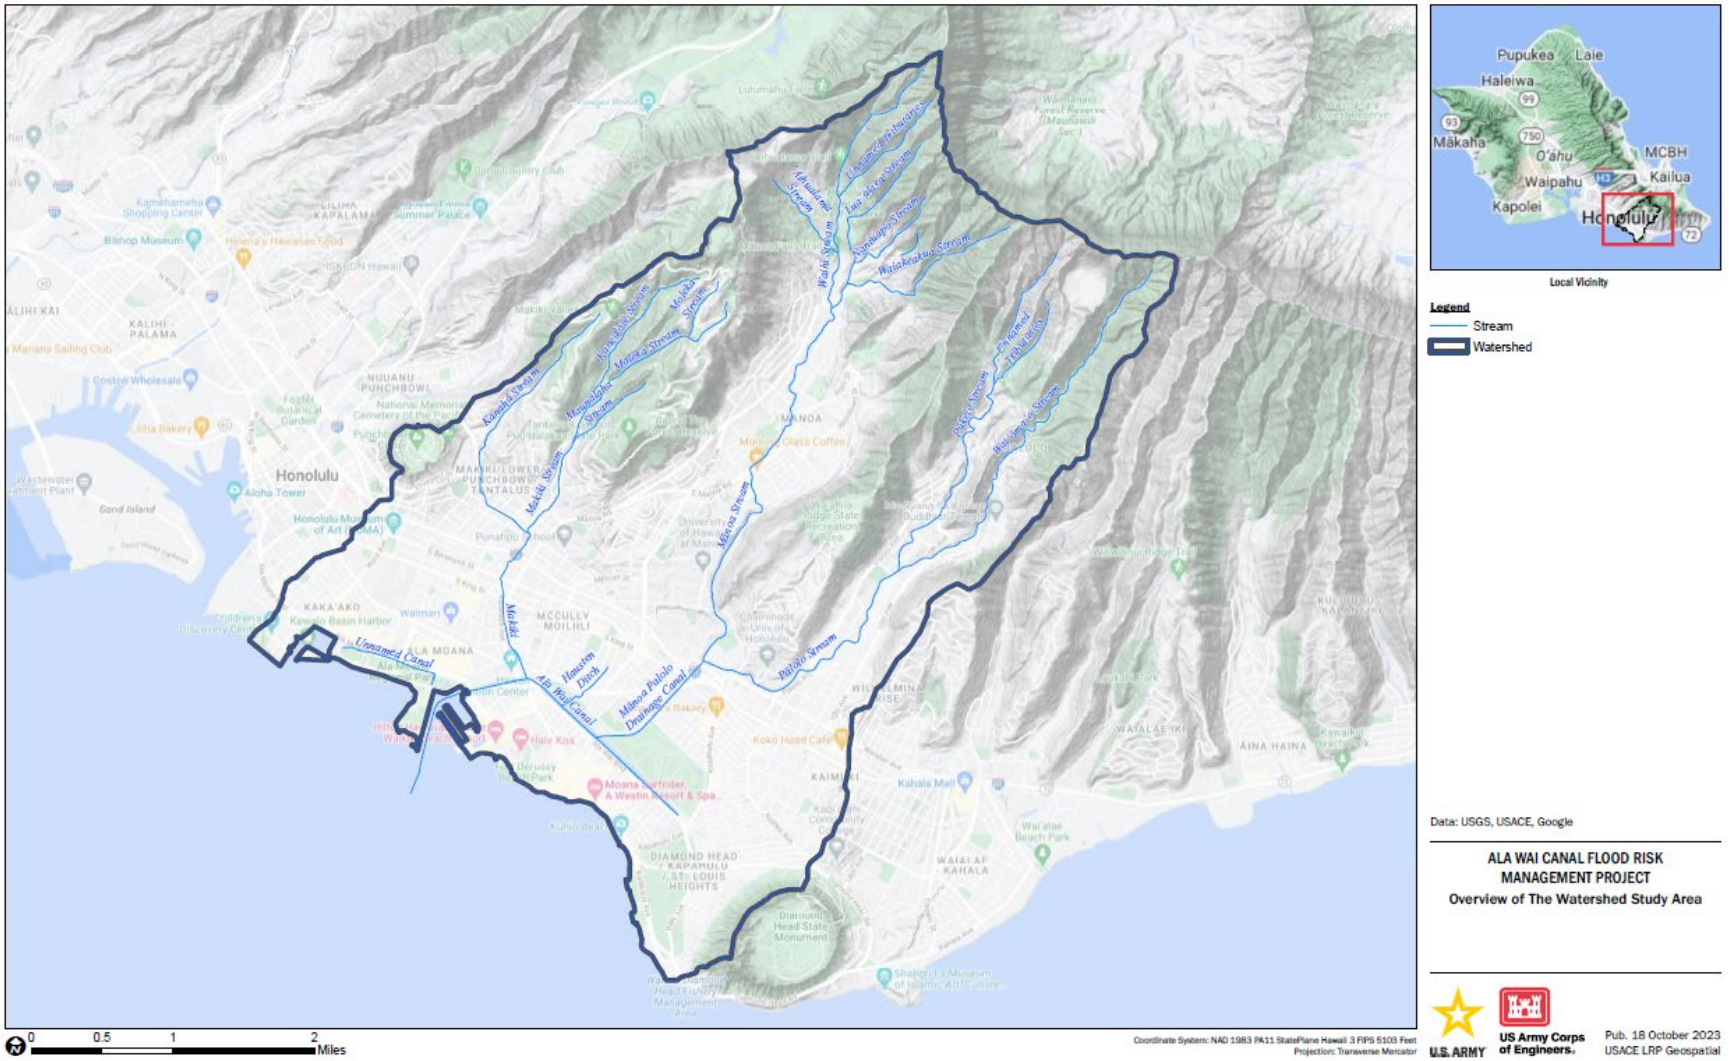

Figure 1: Ala Wai Watershed.

Figure 2: Damage Reach Map.

1.5 Background and History

The Ala Wai Canal General Reevaluation Study represents a congressionally authorized opportunity to reevaluate the outcome of the Ala Wai Canal Flood Risk Management Feasibility Study, O'ahu, Hawaii, which was initiated in April 1999 in response to a request from the Hawaii Department of Land and Natural Resources (DLNR). At that time, federal, state, and local agencies sought a comprehensive management and restoration plan to restore aquatic habitat and biological diversity in the Canal and upstream tributaries. An initial reconnaissance report was submitted in August 1999 recommending that USACE assist the State with restoration of the Canal. Approval by USACE for continuation into the feasibility phase was granted in September 1999.

Independently, a separate study referred to as the Ala Wai Flood Study was initiated in September 1998 under the Planning Assistance to States (PAS) Program (Section 22 of the Water Resources Development Act [WRDA] of 1974) to determine the potential flood risk to the Waikiki area, in response to a request by the DLNR Land Division. The Ala Wai Flood Study was completed in October 2001 and documented flood risks associated with potential

overtopping of the Ala Wai Canal. This study identified several mitigation measures and conceptual alternatives that could potentially minimize flood damages to Waikiki and surrounding areas. Subsequently, a flood risk management objective was added to the Ala Wai Canal Flood Risk Management Feasibility Study, expanding the project focus to both ecosystem restoration and flood risk management in the Canal area.

A Feasibility Cost Share Agreement (FCSA) for the Ala Wai Canal Flood Risk Management Feasibility Study was executed between USACE and the DLNR Engineering Division in 2001. In October 2004, during the initial phases of the Ala Wai Canal Flood Risk Management Feasibility Study, heavy rains caused Manoa Stream to overtop its banks, resulting in significant damages. In response, the USACE temporarily ceased work on the feasibility study, such that the project could be expanded to include the upstream portions of the Ala Wai Watershed. While the FCSA was being amended to address a more comprehensive scope, the U.S. Department of Agriculture (USDA) Natural Resources Conservation Service (NRCS) received federal funds to identify specific actions to address flooding in Manoa Valley. The USDA NRCS effort—referred to as the Manoa Watershed Project—was initiated in 2006 and resulted in detailed topographic mapping, hydrologic and hydraulic modeling, and identification of potential measures to address specific flood problems. Insufficient federal funding led to termination of the Manoa Watershed Project prior to implementation. However, information developed through the Manoa Watershed Project was subsequently incorporated into the Ala Wai Canal Flood Risk Management Feasibility Study, which was restarted in 2007. At this time, efforts were primarily focused on bringing the technical information for the entire watershed up to the same level of detail as produced for Manoa under the Manoa Watershed Project.

In October 2012, a charrette was held to re-scope the study as part of the USACE Civil Works Planning Modernization process. The purpose of the charrette was to bring together the Ala Wai Canal Flood Risk Management Feasibility Study team, USACE Pacific Ocean Division and Headquarters staff, the non-federal sponsor, and other cooperating agencies to determine a path forward for completing the feasibility study in compliance with current USACE planning requirements. Key outcomes of the charrette included consensus on the problems and opportunities, objectives and constraints, screening and decision criteria, the initial array of alternatives, and a framework for identification of the recommended plan. Based on the project review at the charrette, ecosystem restoration was eliminated as a study objective, as it was determined that the biological resources within the watershed do not have enough national significance to adequately justify ecosystem restoration as an objective. However, ecosystem-related information previously identified as part of the Ala Wai Canal Flood Risk Management Feasibility Study was incorporated where possible as part of environmentally sustainable design considerations, particularly as related to maintaining habitats and migratory pathways for native aquatic species.

The Ala Wai Canal Flood Risk Management Feasibility Study was completed in 2017, resulting in a Chief's Report recommending a project that was authorized and funded for design and construction in 2018. A 2020 Engineering Documentation Report provided the technical basis for modifications necessary to ensure the authorized project functioned as intended. However, the *Ala Wai Flood Risk Management Project, Honolulu, Hawaii* Validation Report, dated March 25, 2021, found that the modifications in the 2020 Engineering Documentation Report were not cost effective and lacked the economic justification necessary for continued federal involvement. The current Ala Wai Canal General Reevaluation Study allows the project team to reevaluate whether a federal project for managing flood risk within the Ala Wai Watershed is feasible.

1.6 Purpose and Need

A high level of flood risk exists within the Ala Wai Watershed. Extensive urban development throughout the watershed, coupled with the basin's unique topography and hydrology (i.e., steep mountainous terrain and propensity for intense rainfall events within the headwaters) and aging and undersized infrastructure result in elevated flood risk for a large proportion of the population both along the Ala Wai Canal and within the Makiki, Manoa, and Palolo valleys. The population density within the Ala Wai watershed, with approximately 200,000 residents. The watershed also contains the University of Hawaii and the Waikiki District—a prime tourist destination that attracts more than 79,000 visitors per day and accounts for approximately 8% of the gross state product and 11% of all civilian jobs in the state.

Flooding has occurred within the watershed on multiple occasions, resulting in recorded property damages and health and safety risks. Overtopping of the Ala Wai Canal has previously flooded areas adjacent to the canal multiple times, including November 1965 and December 1967 storms and during the passage of Hurricane Iniki in 1992. Upstream areas are also at risk of flooding, as demonstrated by several recent events, including the October 2004 storm that flooded the Manoa Valley and the March 2006 storm that flooded Makiki. The October 2004 event was estimated to be a 4% annual exceedance probability (AEP) flood event—an event with a 4% chance of being equaled or exceeded in any given year— and caused more than $85M in damages. Analyses conducted in support of this project show that the 1% AEP flood event affects approximately 3,111 structures with an estimated $905,327,000 in structural damages alone (2023 price levels), not accounting for loss in business income or other similar economic losses. This Draft GRR/SEIS analyzes a series of preliminary alternatives designed to reduce the on-going flood risks throughout the Ala Wai watershed, including a no action plan, as well as various combinations of structural, non-structural, and natural and nature-based measures.

1.7 Problems and Opportunities

Two main problems that encompass numerous sub-problems were identified:

- Elevated life risk resulting from riverine flooding along Makiki, Manoa, and Palolo streams and the interplay between riverine and storm surge flooding along the Ala Wai Canal.
    - Elevated life risk to individuals living, working, and visiting areas within the floodplain.
    - Elevated life risk due to the flashy nature of flooding within the watershed and the resulting limited time for warning and evacuation.
    - Elevated life risk resulting from exposure to contaminated floodwaters.
    - Elevated life risk due to inundation of critical facilities.
    - Elevated life risk due to inundation of transportation infrastructure, including access and egress from the watershed, isolation of residents and/or communities, and inundation of occupied vehicles.
- Economic damages resulting from riverine flooding along Makiki, Manoa, and Palolo streams and the interplay between riverine and storm surge flooding along the Ala Wai Canal.
    - Damage to residential and commercial structures and public infrastructure.
    - Impacts to the local economy through disruption of commerce and tourism.
    - Economic damages associated with traffic delays and detours.

Opportunities identified during the charrette were broken down into federal and local opportunities as described below.

Federal opportunities
- Educate the public/stakeholders on current and future flood risks.
- Protect and preserve historical sites and cultural resources throughout the watershed.
- Increase resiliency of communities by managing current and future flood risks.
- Improved ecological conditions through actions that improve habitat and water quality.
- Potential to provide and/or improve recreational opportunities.
- Improved ecosystem services and community relationships with water.
- Reduced life risk throughout the watershed, particularly socially vulnerable populations.
- Reduced economic damages associated with disruptions to commerce and tourism.
- Reduced economic and life safety impacts due to inundation of transportation infrastructure.
- Opportunity to engage with broad stakeholder groups regarding flood risk management desires and opportunities.

Local opportunities
- Opportunity to learn needed climate resilience practices that can be applied in other watersheds and neighborhoods.
- Opportunity to set the stage for additional capital projects.
- Decreased flood insurance costs.

1.8 Objectives and Constraints

An initial scoping charrette held on July 27-30, 2021, that included members of the USACE study team and representatives from the local sponsor and other key stakeholders resulted in the development of the following problems, opportunities, objectives, and constraints.

The following study objectives were developed to provide a means of determining whether project alternatives can address identified problems while maximizing the potential to realize identified opportunities:
- Reduce risks to life and safety associated with direct inundation of structures (residential, non-residential, and critical facilities) and transportation infrastructure due to riverine flooding along Makiki, Manoa, and Palolo streams and the interplay between riverine and storm surge flooding along the Ala Wai Canal over the period of analysis.
- Reduce economic damages associated with direct inundation of structures (residential, non-residential, and critical facilities) & public infrastructure due to riverine flooding along Makiki, Manoa, and Palolo streams and the interplay between riverine and storm surge flooding along the Ala Wai Canal over the period of analysis.
- Reduce economic impacts associated with disruption of commerce and tourism due to riverine flooding along Makiki, Manoa, and Palolo streams and the interplay between riverine and storm surge flooding along the Ala Wai Canal over the period of analysis.

The following constraints (i.e., restrictions that limit the planning process) were identified:
- Inducing further development within the floodplain cannot be included as a goal of the project.

Additional considerations include:
- Presence of protected species and critical habitats throughout the watershed.
- The upper portion of the watershed is zoned as a Conservation District, which is intended to protect natural and cultural resources, including the island's aquifer.
- Real estate costs and limited availability of available real estate may limit feasibility of certain measures.

- Strong cultural ties to the environment and natural resources may affect the acceptability of certain management measures.
- Varied property ownership throughout the watershed (e.g., state or city/county owned but encumbered by a5omple or executive order).
- Private ownership of streambeds represents an important real estate consideration.
- Groundwater influence and high water table may affect applicability of certain measures.
- Potential seismic considerations may influence applicability of certain measures.
- Sea level rise and climate change will likely alter future flood risk.
- Dense development in the lower portions of the watershed may limit the implementability of certain measures.
- Large number of engaged stakeholder groups with potentially competing objectives and desires.
- Potential solutions could have significant impacts on local and regional economy.
- Per Engineer Regulation 1105-2-100, mitigation should be investigated and recommended to address induced flooding when economically justified or if there are overriding reasons of safety, economic or social concerns, or a determination of a real estate takings has been made.

1.9 Study Scope

The study will examine flood risk reduction measures related to inland riverine flooding in the Ala Wai Watershed. This study will not examine coastal storm risk management measures.

Chapter 2: Plan Formulation and Evaluation

2.1 Planning Framework

The USACE's planning process is based on the *Economic and Environmental Principles and Guidelines for Water and Related Land Resources Implementation Studies* promulgated in 1983 (U.S. Water Resources Council 1983). The Principles and Guidelines provide for development of reasonable plans that are responsive to federal, state, and local concerns. Planning project benefits are quantified in this process as National Economic Development (NED) output, National Ecosystem Restoration (NER) output, or a combination of NED/NER output.

2.2 Assumptions

The following assumptions underpin the development, evaluation, and comparison of alternative flood risk management plans:

- Engineering and economics model outputs created as part of the 2017 engineering documentation report are sufficient to inform the initial development and assessment of flood risk management measures.
- A full interior drainage analysis will be completed during the PED phase. Thus, modifications to the recommended plan could be required during PED based on the outcome of those analyses.
- Efforts to address potential induced flooding were undertaken in accordance with USACE policy and guidance, which directs development of mitigation when economically justified, if there are overriding reasons of safety, economic, or social concerns, and/or if a determination of a real estate taking has been made. The study team acknowledges that recent case law regarding what level of induced flooding constitutes a takings may change how USACE interprets and implements policy regarding induced flooding and will include those potential risks in discussions and analyses moving forward.

2.3 Management Measures

A total of 224 management measures—or actions that can be taken to meet the planning objectives throughout the watershed—were identified by the USACE study team or brought forth by members of the public during public workshops held during the current Ala Wai Canal General Reevaluation Study or the previous feasibility study. The main management categories and associated descriptions, comprising the 224 management measures which were assessed, are provided in Table 1. Management measure types were categorized as follows:

- Structural (S) Measures: Measures that reduce or avoid damages by modifying the nature and/or extent of the flood hazard.
- Nonstructural (NS) Measures: Measures that reduce or avoid damages by modifying the consequences of the flood hazard.
- Natural and Nature-Based (NNB): Measures that alter, restore, use, or mimic natural landscape features or processes to manage flood risk.

The total number of management measures in each category are also provided in Table 1.

Table 1: Management Measure Categories.

Category	Description	Type	No.
Bridge Modification	Modify bridges identified as choke points on tributaries to increase capacity and reduce risk of adjacent inundation.	S	4

Category	Description	Type	No.
Bypass	Construction of a channel bypass to divert floodwaters away from a damage center or problem area, discharging back into the same drainage. Channel bypasses could be above or below ground, including large-scale tunnels or conduits.	S	44
Channel Modification	Widening, deepening, and/or lining of the channel to increase capacity and conveyance and prevent overtopping. Modification could occur along the tributaries, as well as the Ala Wai Canal.	S	20
Pumps	Construction of interior pumping stations to increase the rate at which floodwaters drain, reducing inundation extents and durations.	S	9
Debris Management	Measures designed to strategically capture debris during high-flow events to reduce downstream risks (e.g., direct damage and blockage/altered hydraulics).	S	11
Detention	Detention basins to store water either on (online) or off (offline) the stream network during high-flow events. Offline detention could be above ground within existing open space and/or underground.	S	58
Floodwall/Levee	Construction of a floodwall or levee along the Ala Wai Canal (i.e., construction of new floodwall or raising of existing canal walls) or its tributaries to reduce risk of inundation in adjacent areas. Floodwalls and levees could be integrated into more aesthetic, park-like features.	S	14
Gates	Control structures within or at the outlet of the Ala Wai Canal to permit lowering the water level and increasing storage and/or controlling tidal and storm surge influence. Also includes flap gates on existing drainage systems.	S	6
Grade Control Structure	Construction of grade control structures (e.g., weirs, stilling basin) to slow water velocities in the tributaries, reducing peak flows downstream and decreasing erosion and sediment.	S	6
Other	Structural measures that do not fit cleanly into more common management measure types.	S	3
Nonstructural	Physical (e.g., acquisition and relocation, floodproofing, and elevation) and nonphysical (e.g., flood warning system, risk communication, education, and planning) measures.	NS	10
Reforestation	Actions taken to protect, preserve, manage, and restore natural resources at the watershed scale (e.g., reforestation and restoring native vegetation) that restore natural process and reduce flood risk.	NNB	8
Water Quality	Measures, such as filter strips, that could be implemented in coordination with other flood risk management measures to improve water quality, as permitted by USACE policy.	NNB	4

Category	Description	Type	No.
Wetland/Floodplain	Creation or restoration of wetlands, riparian areas, and floodplains within available open space to store and dissipate flood waters.	NNB	11
Channel Naturalization	The process of restoring the geomorphic characteristics of natural stream channels, such as geometry, access to adjacent floodplains, and meanders, to increase the natural capacity of the river and reduce flood risk. This measure could also include restoring the natural stream bed and daylighting.	NNB	6
Impervious Surface Reduction	Reduce impervious surfaces and increase pervious surfaces (e.g., pervious pavement, green roofs) to reduce runoff and promote infiltration.	NNB	9
No Action	No measures would be implemented by the federal government to achieve the planning objectives.	NA	1

All 224 management measures were evaluated and either retained or screened from further consideration prior to alternative formulation. Management measure screening was conducted in two phases. Phase 1 involved a high-level assessment of engineering feasibility and policy compliance. Measures remaining after Phase 1 screening were then tiered to prioritize additional analyses and maximize analytical efficiency. Phase 2 screening criteria, descriptions, and metrics are provided below in Table 2. When possible, existing data were used for screening during Phase 2.

Table 2: Screening Criteria for Management Measures.

Criteria	Description	Metric(s)
Efficiency	Cost effectiveness—comparison of economic benefits and project costs.	Semi-quantitative – comparison of preliminary costs and expected benefits
Effectiveness (Damages Reduced)	Damages to buildings, related contents, and vehicles.	Semi-quantitative – expected benefits based on previous study iterations
Effectiveness (Life Safety)	Changes in life safety risk expected with alternative implementation.	Semi-quantitative – expected benefits based anticipated water surface elevation reductions.
Acceptability	The viability and appropriateness of an alternative from the perspective of the nation's general public and consistency with existing federal laws, authorities, and public policies.	Qualitative – Description
Environmental Effects	Effects to aquatic (stream, wetland) and terrestrial (riparian, upland) habitats, water quality, and threatened/endangered species	Qualitative – Low, medium, high based on footprint of each alternative.

Screening results for all measures are provided in the management measures tracking spreadsheet which can be found on the City & County of Honolulu's website (https://www.honolulu.gov/alawai/resources.html) and it is also provided in the Plan Formulation Appendix (Appendix A) for this report.

2.4 Arrays of Alternatives

The names and descriptions of the 30 management measures incorporated into the formulation of alternative plans is provided in Table 3.

A cornerstone approach, also known as the first added plan formulation approach, was used to formulate alternative flood risk management plans. The cornerstone approach utilizes a single measure as the starting point for formulating an alternative plan. Subsequently, additional measures are added which complement the cornerstone measure and the additional measures are intended to increase both the effectiveness and efficiency of the alternative plan. Formulation of the alternative plan stops once no further measures can be incorporated into the alternative plan which make it more effective and efficient. Table 3 provides the outcome of the initial plan formulation process, indicating whether each measure was included in each alternative (Y=yes) within the initial array and whether it was included as a cornerstone (C=cornerstone). The description and each measure type (S=structural; NS=nonstructural; NNB=natural and natures based; NA=not applicable) are also provided.

Table 3: Management Measures Used in Formulation of Alternative Plans

	Inclusion in at Least 1 Iteration of Plan Formulation										
Name	**0**	**1**	**2A**	**2B**	**2C**	**3**	**4**	**5**	**6**	**Description**	**Type**
Ala Wai Canal Floodwall		Y	Y	C	Y	Y	Y	C		Floodwall system along the Ala Wai Canal that may extend up the Manoa-Palolo Canal and Makiki.	S
Ala Wai Canal Tunnel (2nd Outlet)				Y						Eastern end of canal will be extended via subsurface tunnel as a second outlet to the ocean.	S
Ala Wai Golf Course Detention		C				Y	Y	Y		Design the Ala Wai Golf Course to include berm features for increased storage near the canal.	S
Daylight Ala Wai Canal (2nd Outlet)					C					Eastern end of canal will be extended via daylighting as a second outlet to the ocean.	S
Dredge Ala Wai Canal			Y	Y				Y		Ala Wai Canal will be dredged to its design depth or acceptable level of dredging, considering environmental impacts, stability, and structural integrity.	S
Dredge Manoa-Palolo Canal			Y	Y			Y			Dredge Manoa-Palolo Canal to increase storage and conveyance from Palolo and Manoa.	S
Kaimuki High School Berm / Floodwall		Y					Y			Extension of the Ala Wai Canal floodwall adjacent to/in the playing fields of the Kaimuki High School.	S
Kanaha Floodwall		Y	Y	C	Y		Y	Y		Floodwall on the Kanaha Stream where water jumps bank and flows towards Ala Moana.	S
Kapiolani Park Detention Basin		Y								Divert water to Kapiolani Park for additional flood storage.	S
Koali Road Floodwall		Y	Y	C	Y		Y	Y		Floodwall along the Manoa and Palolo Streams along Koali Rd, downstream of Kanewai Park.	S
Makiki District Park Detention		C		Y	Y		Y	Y		Makiki District Park multi-purpose detention pond.	S
Makiki Tunnel						C				Subsurface tunnel diverting water from the headwaters	S

	Inclusion in at Least 1 Iteration of Plan Formulation										
Name	**0**	**1**	**2A**	**2B**	**2C**	**3**	**4**	**5**	**6**	**Description**	**Type**
										of the Makiki Stream to the harbor/ocean.	
Manoa Valley District Park Detention		C	Y				Y	C		Manoa Valley District Park multi-purpose detention pond.	S
Waikiki Bypass			C	Y						Utilize existing storm sewer system or add bypasses from the Ala Wai Canal to the ocean.	S
Paki Ave Bypass			C							Utilize existing storm sewer system along Paki Ave as a bypass for Ala Wai Canal waters.	S
Palolo Channel Modification			Y				Y	Y		Deepen or widen channel to provide more within-bank storage.	S
Palolo Culverts			C							Bypass from Palolo Stream along Kapahulu Ave to Waikiki Wall outfall by upgrading existing storm sewer infrastructure.	S
Palolo Valley District Park Detention		Y					Y			Palolo Valley District Park multi-purpose detention pond.	S
Piikoi Street Bypass			C			Y	Y	Y		Bypass from Kanaha Stream down Piikoi Street to Ala Moana Park by upgrading/utilizing existing storm sewer infrastructure.	S
Pumps/other structures		Y	Y	Y	Y	Y	Y	Y		Pumps and other structures, such as flap gates, to mitigate interior drainage impacts of other measures.	S
SWIFT Tunnel (Manoa)						C				Subsurface tunnel diverting water from the headwaters of the Manoa Stream to the harbor/ocean.	S
SWIFT Tunnel (Palolo)						C				Subsurface tunnel diverting water from the headwaters of the Palolo Stream to the harbor/ocean.	S
Woodlawn Drive Floodwall		Y	Y	C	Y	Y	Y	Y		Floodwall along Manoa Stream at Woodlawn Drive bridge.	S

	Inclusion in at Least 1 Iteration of Plan Formulation										
Name	**0**	**1**	**2A**	**2B**	**2C**	**3**	**4**	**5**	**6**	**Description**	**Type**
Woodlawn Bridge Modification		Y								Modify the bridge at Woodlawn Drive to increase conveyance.	S
Woodlawn Channel Modification		Y			Y		Y	Y		Channel modification along Manoa Stream near Woodlawn Drive bridge.	S
Woodlawn Drive Bypass		Y	C	Y			Y	C		Bypass of Manoa Stream at Woodlawn Drive by constructing new inlet and upgrading/utilizing existing storm water infrastructure.	S
Nonstructural Measures		Y	Y	Y	Y	Y	Y	Y	Y	Physical (e.g., acquisition and relocation, floodproofing, and elevation) and nonphysical (e.g., flood warning system, risk communication, education, and planning) measures.	NS
Watershed Management							C			Removing invasive species and replanting with native species; controlling ungulates to reduce destruction of vegetation; and reducing impervious surfaces.	NNB
Daylight Makiki Stream		Y	Y				Y			Increasing conveyance and reducing restrictions along Makiki Stream by daylighting.	NNB
No Action	Y									No federal action.	NA

A summary of screening results for the final iteration of each alternative are provided in Table 4. A full description and evaluation of all iterations for each alternative is presented in the Plan Formulation Appendix.

Table 4: Evaluation Summary of the Initial Array of Alternatives.

Alt.	Effic.	Effect. (Damages)	Effect. (Lif. Saf.)	Effect. (Comm./Tour.	Accept.	Env.	Comp.
0	No	No	No	No	No	No	Positive
1	Positive	Positive	Positive	Positive	No	Positive	Positive
2A	Negative	Negative	Negative	Negative	No	No	Positive
2B	Positive	Positive	Positive	Positive	No	No	Positive

3	Negative	No	No	No	No	Negative	Positive
4	Negative	Negative	Negative	Negative	Positive	Positive	Positive
5	Positive	Positive	Positive	Positive	No	No	Positive
6	Positive	Positive	No	Positive	No	Positive	Positive

The rationale for screening or retaining alternatives is provided below:

Alternative 0. No Action Plan. USACE planning policy (Engineering Regulation 1105-2-100) and NEPA require consideration of 'No Action'. The No Action alternative assumes no measures would be implemented by the federal government to achieve the planning objectives.

Alternative 1. Storage Cornerstone. Based on the benefits calculations provided by previous studies, the storage cornerstone is likely to have positive net benefits. It is also expected to be effective at providing flood risk reduction benefits associated with all 3 study objectives—damage reduction, life safety risk reduction, and reduced impacts to commerce and tourism—throughout the watershed. Alternative 1 would also have minimal impacts to aquatic and terrestrial habitats, as well as some benefit to water quality through increased infiltration. Benefits to socially vulnerable populations in the lower portion of the watershed would likely still experience risks due to flooding along the Ala Wai Canal. Alternative 1 would be compatible with laws, regulations, and policies; however, use of public parks as detention facilities could reduce acceptability by the public.

Alternative 2A. Conveyance (Existing Infrastructure) Cornerstone. Cornerstone measures included in Alternative 2A, including the Piikoi, Woodlawn Drive, Waikiki, and Paki Avenue Bypasses, and the Palolo Culverts, were found to be largely ineffective at reducing water surface elevations and were screened out during various iterations of the plan formulation process. As a result, Alternative 2A was screened from further consideration.

Alternative 2B. Conveyance (Floodwalls) Cornerstone. Based on the benefits calculations provided by previous studies, the storage cornerstone is likely to have positive net benefits. It is also expected to be effective at providing flood risk reduction benefits associated with all 3 study objectives—damage reduction, life safety risk reduction, and reduced impacts to commerce and tourism—throughout the watershed. Alternative 2B would have some impact to riparian and marine habitats, including increasing the rate at which contaminants reach the ocean. Alternative 2B would be compatible with laws, regulations, and policies; however, extensive floodwalls along the Ala Wai Canal could reduce acceptability by the public.

Alternative 2C. Conveyance (2nd Outlet) Cornerstone. Based on the benefits calculations provided by previous studies and preliminary costs, it was determined that the Ala Wai Canal 2nd Outlet would not have positive net benefits. Through coordination with partnering resource agencies, it was also determined that a 2nd canal outlet would also have significant environmental effects on marine resources and would also impact the tourism industry through

impacted water quality along Waikiki Beach. As a result, Alternative 2C was screened from further consideration.

Alternative 3. Tunnel Cornerstone. Modeling results and preliminary cost estimates indicate that the water surface elevation reductions and associated benefits would not be sufficient to offset the costs of tunnel construction. Through coordination with partnering resource agencies, it was also determined that a 2nd canal outlet would also have significant environmental effects on marine resources. As a result, Alternative 3 was screened from further consideration.

Alternative 4. Natural and Nature-Based Cornerstone. Sensitive analysis and modeling results quantifying the potential benefits associated with watershed management activities, including reforestation, invasive management, and reducing imperviousness, indicate that these activities would not be effective at modifying hydrology and hydraulics at events larger than the 50% AEP event. Thus, the cornerstone measures for Alternative 4 would be ineffective at reducing risk during the events that drive risk throughout the watershed. As a result, Alternative 4 was screened from further consideration.

Alternative 5. Hybrid Cornerstone. Based on the benefits calculations provided by previous studies and preliminary costs, Alternative 5 is likely to have positive net benefits. It is also expected to be effective at providing flood risk reduction benefits associated with all 3 study objectives—damage reduction, life safety risk reduction, and reduced impacts to commerce and tourism—throughout the watershed. Alternative 5 would have some impact to riparian and marine habitats, including increasing the rate at which contaminants reach the ocean; however, increasing storage and infiltration may work to reduce impacts to water quality. Alternative 5 would be compatible with laws, regulations, and policies; however, use of public parks as detention facilities and extensive floodwalls along the Ala Wai Canal could reduce acceptability by the public.

Alternative 6. Nonstructural Cornerstone. Based on the benefits calculations provided by previous studies and preliminary costs, it was determined that nonstructural measures would have positive net benefits in many portions of the watershed. It is also expected to be effective at providing flood risk reduction benefits associated with all 3 study objectives—damage reduction, life safety risk reduction, and reduced impacts to commerce and tourism—throughout the watershed. However, lower participation rates could render this alternative incomplete and impact overall efficiency. Alternative 6 would have minimal impact on environmental resources.

Final Array of Alternatives.
The final array consisted of 5 alternatives, as outlined below.

No Action (Future Without-Project)

As discussed above, USACE planning policy (Engineering Regulation 1105-2-100) and the NEPA require consideration of 'No Action'. The No Action alternative or the future without-project condition assumes no measures would be implemented by the federal government to achieve the planning objectives.

The future without-project condition is defined as the most likely condition expected to exist in the future in the absence of the project and serves as the benchmark against which other alternatives are evaluated. In general, future without-project forecasting should account for conditions such as climate variability, sea-level rise, subsidence, geomorphologic changes, and changes in development over the 50-year period of analysis. Based on an analysis of the anticipated future conditions within the watershed, the future without-project condition for the

study area was defined according to changes in sea-level, rainfall frequency, debris generation, and transport, and extent of impervious area. Substantial changes in land subsidence, seismic influences, and geomorphologic conditions are not expected over the period of analysis, so were not further evaluated. A detailed discussion of these conditions is provided in Chapter 3.

Under the No Action Alternative (future without project), a variety of flood-related effects would not be addressed, and the Honolulu community would remain vulnerable to the effects of flooding and storm damage. If no action is taken, it is anticipated that (1) vegetated areas within the floodplain would be subject to flooding; (2) recreational areas would continue to be subject to flooding; (3) roadways would continue to be at risk of flooding; (4) flood-related health and safety risks would not be addressed; and (5) critical infrastructure would not be removed from the floodplain. There would also be the risk of heavy metals and petroleum products being mobilized due to potential flood damage to residential and non-residential structures and vehicles and that such contaminants may present a risk to natural resources within the Ala Wai watershed. A large portion of the watershed, including approximately 52,000 residents (plus between 70,000 and 100,000 visitors daily), would remain within the 1% AEP flood event. In addition to threatening public health and safety, a large-scale flood event would be expected to result in significant structural damages associated with the 1% AEP flood, which are approximately $960 million. Emergency costs associated with responding to the flood event, impacts to critical infrastructure, and disruptions to local business would also be substantial.

Alternative 1 (Storage Cornerstone)

Alternative 1 primarily focuses on increasing storage throughout the Ala Wai watershed to reduce flood risk. Implementation of this alternative would include the construction of the following detention basins and floodwalls in strategic locations.

Makiki District Park Detention Basin–- At Makiki District Park, in Makiki Valley, a detention basin (i.e., Makiki District Park Detention Basin) would be constructed to temporarily store stormwater runoff. The detention basin would collect, and store stormwater which would then be released gradually back into Makiki Stream until the detention basin is completely drained. The detention basin would be constructed by excavating down approximately 6 to 10 ft and constructing a floodwall made of steel sheetpile and earthen slopes and 6 ft in height around the perimeter of the park (floodwall would be approximately 1,200 ft in length). The Makiki District Park Detention Basin would have a storage volume of approximately 22 acre-feet. An approximately 20 ft (H) x 4 ft (W) x 525 ft (L) concrete box culvert would be constructed at the upstream end of the detention basin as an inlet for stormwater from Makiki Stream. An approximately 1.75 ft (H) x 1.75 ft (W) X 1,205 ft (L) concrete box culvert would be constructed at the downstream end of the detention basin as an outlet for collected stormwater to slowly drain to Makiki Stream. Also, within Makiki Valley, a floodwall extending 6 ft above ground level (i.e., Kanaha Floodwall) would be constructed along the right descending bank of Makiki Stream. The floodwall would be approximately 2,200 ft long and would be constructed of macropiles with a concrete fascia. The Kanaha Floodwall would extend approximately from Mott Smith Drive downstream to Anapuni Street. Five road closure structures would be constructed to bridge the gap between the floodwall as it crosses (1) Liholiho Street, (2) private driveway, (3) Kewalo Street, (4) Ke'eaumoku Street, and (5) Makiki Street. The road closure structures would likely be constructed of aluminum stop logs that would be inserted in anticipation of a storm event to form a continuous line of protection with the floodwall; however, the actual design has not been determined yet. The purpose of the Makiki District Park Detention Basin is to work in conjunction with the Kanaha Floodwall to reduce the risk of flooding for adjacent residential communities located to the south of the floodwall.

Manoa Valley District Park Detention Basin–- At Manoa Valley District Park, in Manoa Valley, a

detention basin (i.e., Manoa Valley District Park Detention Basin) would be constructed. The detention basin would collect, and store stormwater which would then be released gradually back into Manoa Stream until the detention basin is completely drained. The detention basin would be constructed by excavating down approximately 6 to 8 ft and constructing a floodwall made of steel sheetpile and earthen slopes and 6 ft in height around the perimeter of the park (floodwall would be approximately 1,580 ft in length). The Manoa Valley District Park Detention Basin would have a storage volume of approximately 54 acre-feet. An approximately 15 ft (H) x 4.5 ft (W) x 445 ft (L) concrete box culvert would be constructed at the upstream end of the detention basin as an inlet for stormwaters from Manoa Stream. An approximately 2 ft (H) x 2 ft (W) channel would be excavated at the downstream end of the detention basin as an outlet for collected stormwater to slowly drain to Manoa Stream. The purpose of the Manoa Valley District Park Detention Basin is to reduce the risk of flooding to residential structures downstream of the park.

Woodlawn Drive Floodwall and Koali Road Floodwall–- Also within Manoa Valley, a floodwall extending 6 ft above ground level (i.e., Woodlawn Drive Floodwall) would be constructed along the right descending bank of Manoa Stream. The floodwall would be approximately 1,270 ft in length. A single road closure structure at Woodlawn Drive would be constructed. The Woodlawn Drive Floodwall would reduce the risk of flooding to the University of Hawaii and downstream residential structures due to overtopping at Woodlawn Drive Bridge. At Koali Road, near the convergence of Manoa and Palolo streams, a floodwall extending 6 ft above ground (i.e., Koali Road floodwall) would be constructed along the left descending bank of Manoa Stream and the right descending bank of Palolo Stream. The floodwall would be approximately 2,510 ft in length. Two concrete drainage structures would be constructed to provide interior drainage of stormwater flows from the residential neighborhood behind the Koali Road floodwall. Two flap gates would be retrofitted on smaller stormwater culverts along this feature. Two road closure structures would be constructed — one at Koali Road and one at the pedestrian bridge crossing Palolo upstream (approximately 690 ft upstream of Koali Road Bridge) — to bridge the gap between the floodwall as it crosses these two throughways. The purpose of the Koali Road Floodwall is to reduce risk to adjacent residential structures, including induced damages caused by the Woodlawn Drive Floodwall. Thus, the Woodlawn Drive Floodwall and Koali Road Floodwall function as a system.

Kaimuki High School Floodwall–- At Kaimuki High School, adjacent to the Manoa-Palolo Canal, a floodwall extending 6 ft above ground (i.e., Kaimuki High School Floodwall) would be constructed along the left descending bank of Manoa-Palolo Canal. The floodwall would be approximately 4,400 ft long and would be constructed of a combination of steel sheetpile (2,700 ft) and macropiles (1,700 ft) with concrete fascia. The Kaimuki High School floodwall would extend around the perimeter of Kaimuki High School's athletic fields. Two road closure structures would be constructed — one at Kapiolani Boulevard and one as South King Street along the left descending bank of the Manoa-Palolo Canal — to bridge the gap between the floodwall as it crosses these two throughways. The purpose of the floodwall would be to reduce the risk of flooding to residential structures east/southeast of Kaimuki High School.

Ala Wai Golf Course Detention Basin–- At Ala Wai Golf Course, adjacent to the Manoa-Palolo Canal and the Ala Wai Canal, an earthen levee approximately 6 ft in height would be constructed around the perimeter of Ala Wai Golf Course to create a detention basin (i.e., Ala Wai Golf Course Detention Basin). The total length of the earthen levee would be approximately 10,665 ft in length. The golf course detention basin would have a storage volume of approximately 314 acre-feet. A concrete in-stream weir diversion structure would be constructed approximately 50 feet downstream of the Date Street Bridge, along the left descending bank of

the Manoa-Palolo Canal, and at the downstream end of an existing drainage ditch running parallel to Date Street. The dimensions of the weir would be approximately 33 ft (W) x 147 ft (L) x 14.5 (H). The diversion weir would allow stormwater to enter the golf course detention basin starting at the 5% AEP—an event with a 5% chance of being equaled or exceeded in any given year— flood event. Three concrete drainage structures with flap gates would be constructed along the southwest side of the Ala Wai Golf Course to allow collected stormwater to slowly drain into the Ala Wai Canal. The three drainage structures would be approximately 3 ft (W) X 3 ft (H) and would be located at the downstream end of three existing natural drainages along the southwest side of the golf course (west of the Ala Wai Golf Course Clubhouse). Three road closure structures would be constructed – one at the entrance to the golf course maintenance facility (off Date Street), one at Date Street to connect the Kaimuki High School floodwall, and one at Ala Wai Golf Course Drive – to bridge the gap between the floodwall as it crosses these two roadways. The purpose of the Ala Wai Golf Course Detention Basin would be to reduce the risk of flooding within Waikiki.

Mitigation Measures – Mitigation measures related to induced flooding include potentially adding permanent pump station(s) of moderate to large size, ranging from 500 to 20,000 cubic feet/second (cfs). At the time of compiling this Draft Report, it is unknown as to the number of pumps that may be necessary to minimize induced flooding, the size of the pumps, or the location of pumps within the watershed. If Alternative 1 moves forward, additional analysis would be conducted during the PED to determine the above and appropriate supplemental NEPA analysis and coordination would be conducted as necessary. In addition to considering pumps as potential mitigation for induced flooding within the watershed, nonstructural measures such as dry/wet floodproofing, elevation, and acquisition are also under consideration. Similar to the above, if Alternative 1 moves forward, additional analysis would be conducted during PED to determine the precise number and location of structures recommended for dry/wet floodproofing, elevation, or acquisition. Appropriate supplemental NEPA analysis and coordination would be conducted as necessary.

Alternative 2B (Conveyance Cornerstone)

In addition to the measures listed below, Alternative 2B also includes the Makiki District Park Detention Basin, Woodlawn Drive Floodwall, and Koali Road Floodwall all of which are described above under Alternative 1.

Kaimuki High School Floodwall– At Kaimuki High School, adjacent to the Manoa-Palolo Canal, a floodwall extending 6 ft above ground (i.e., Kaimuki High School Floodwall [extension of Ala Wai Canal Floodwall]) would be constructed along the left descending bank of Manoa Manoa-Palolo Canal. The floodwall would be approximately 3,360 ft long and would be constructed of a combination of macropiles (1,030 ft) and steel sheetpile (2,330 ft) with concrete fascia. The floodwall would extend around the perimeter of Kaimuki High School's athletic fields. This floodwall differs from the Kaimuki High School Floodwall described under Alternative 1 because th12ompleteall essentially stops near the Kaimuki High School's discus and shot put throwing area. Instead of running parallel to Date Street, the Kaimuki High School's floodwall would join up with the Ala Wai Canal Floodwall discussed below. The purpose of the floodwall would be to reduce the risk of flooding to residential structures east/southeast of Kaimuki High School.

Ala Wai Canal Floodwall– At Ala Wai Golf Course, Manoa-Palolo Canal, and Ala Wai Canal, a floodwall extending 6 ft above ground (i.e., Ala Wai Canal Floodwall) would be constructed. The floodwall would be approximately 24,745 ft long and constructed of a combination of macropiles (20,005 ft) and steel sheetpile (4,740 ft) with concrete fascia. The floodwall would extend along (1) the right descending bank of Manoa-Palolo Canal from approximately Interstate H-1

downstream to the Ala Wai Canal, (2) from Kaimuki High School Floodwall along Date Street to the southeast (adjacent to the Ala Wai Golf Course) and extending along the east/southeast side of the golf course that runs parallel to Kapahulu Avenue, and (3) along the left and right descending banks of the Ala Wai Canal downstream to Ala Moana Boulevard. Six existing stormwater sewers inletting into the Ala Wal Canal would be modified to include a flap gate which would permit the free flow of interior drainage into the Ala Wai Canal while preventing and sealing against backflow. One existing stormwater sewer inlet that would be modified runs parallel to Date Street, adjacent to the Ala Wai Golf Course. The remaining stormwater sewer inlets that would be modified are located along the right descending bank of the Ala Wai Canal within the area between Ala Wai Elementary School and Sunset Towers. Nine road closure structures would be constructed at (1) Kapiolani Boulevard, (2) Date Street (near the Date Street and Laau Street junction), (3) Date Street (near the vicinity of the Kaimuki High School's discus and shot put throwing area, (4) Ala Wai Golf Course Maintenance Facility driveway, (5) Ala Wai Golf Course Drive, (6) McCully Street (Ala Wai Canal right descending bank), (7) McCully Street (Ala Wai Canal left descending bank), (8) Kalakaua Avenue (Ala Wai Canal right descending bank), and (9) Kalakaua Avenue (Ala Wai Canal left descending bank). The purpose of the road closure structures would be to bridge the gap between the Ala Wai Canal Floodwall as it crosses these nine roadways. The purpose of the Ala Wai Canal Floodwall would be to reduce the risk of flooding within the McCully-Moiliili neighborhood, Diamond Head neighborhood, and Waikiki.

Mitigation Measures – Mitigation measures related to induced flooding include potentially adding permanent pump station(s) of moderate to large size, ranging from 500 to 20,000 cfs. At the time of compiling this Draft Report, it is unknown as to the number of pumps that may be necessary to minimize induced flooding, the size of the pumps, or the location of pumps within the watershed. If Alternative 2B moves forward, additional analysis would be conducted during the Preconstruction Engineering and Design (PED) phase to determine the above and appropriate supplemental NEPA analysis and coordination would be conducted as necessary. In addition to considering pumps as potential mitigation for induced flooding within the watershed, nonstructural measures such as dry/wet floodproofing, elevation, and acquisition are also under consideration. Similar to the above, if Alternative 2B moves forward, additional analysis would be conducted during PED to determine the precise number and location of structures recommended for dry/wet floodproofing, elevation, or acquisition. Appropriate supplemental NEPA analysis and coordination would be conducted as necessary.

Alternative 5.3 (Hybrid and Tentatively Selected Plan)

In addition to the measures listed below, Alternative 5.3 includes the Woodlawn Drive Floodwall and Koali Road Floodwall, both of which are described above under Alternative 1.

Kaimuki High School Floodwall– At the Kaimuki High School, adjacent to the Manoa-Palolo Canal, a floodwall extending 6 ft above ground (i.e., Kaimuki High School Floodwall [extension of Ala Wai Canal Floodwall]) would be constructed along the Kaimuki High School's track field and extending down to the vicinity of the Kaimuki High School's discus and shot-put throwing area. The floodwall would be approximately 3,260 ft long and would be constructed of a combination of steel sheetpile (1,460 ft) and macropiles (1,800 ft) with a concrete fascia. The Alternative 5.3 Kaimuki High School Floodwall would be shorter in length than the Kaimuki High School Floodwall described under Alternative 1 and Alternative 2B. Like Alternative 2B, though, the Kaimuki High School Floodwall would join up with the Ala Wai Canal Floodwall discussed below. The purpose of the floodwall would be to reduce the risk of flooding to residential structures east/southeast of Kaimuki High School.

Ala Wai Golf Course Detention Basin – At Ala Wai Golf Course, adjacent to the Manoa-Palolo Canal and the Ala Wai Canal, an earthen levee approximately 6-9 ft in height would be constructed around the perimeter of Ala Wai Golf Course to create a detention basin (i.e., Ala Wai Golf Course Detention Basin). The total length of the earthen levee would be approximately 8,315 ft in length and would extend along the perimeter of the Ala Wai Golf Course along the Manoa-Palolo and Ala Wai canals. On the left descending bank of the Manoa-Palolo Canal, there is an overtopping spillway section, approximately 100 feet in length, that is reinforced with erosion protection. The levee along the Manoa-Palolo Canal is also lined with erosion protection on the canal-side. A portion of the existing drainage ditch that runs along the north side of the golf course (parallel to Date Street) would be riprapped and used as an inlet location for overflow into the Ala Wai Golf Course Detention Basin. A small inlet channel would be excavated and lined with erosion control material to improve the flow onto the golf course. Three concrete drainage structures and three flap gates would be constructed along the levee alignment of the Ala Wai Golf Course to allow collected stormwater within the basin and from local runoff to slowly drain into Ala Wai Canal. The three drainage structures would be approximately 3 ft (W) x 3 ft (H) and would be located at the downstream end of three existing natural drainages along the southwest side of the golf course (west of the Ala Wai Golf Course Clubhouse). The detention basin also includes a floodwall along the golf course parking lot near the Ala Wai Canal, which is 9 ft in height. The floodwall has one concrete drainage structure and two flap gates. The drainage structure at this location serves to outlet flow from the Diamond Head neighborhood. The original outlet will be enclosed by concrete (instead of daylighted) and will need reconstruction of the vehicle and pedestrian access at this location. A small section of floodwall near the Kapahulu Avenue and Ala Wai Boulevard intersection at the Diamond Head end of the canal will tie-in to the golf course levee and Ala Wai Canal floodwall system. This section is 6 ft in height and includes one road closure structure and one drainage structure. Finally, there is one canoe access point in this location. The Ala Wai Golf Course Detention Basin would reduce the risk of flooding within the lower watershed.

Ala Wai Canal Floodwall–- At the Manoa-Palolo Canal and Ala Wai Canal, a floodwall extending 6 ft above ground (i.e., Ala Wai Canal Floodwall) would be constructed. The floodwall would be approximately 22,852 ft long and would be constructed of a combination of J-wall on macropiles (17,125 ft), L-wall on macropiles (4,069 ft), and tieback I-wall (1,658 ft) with a lava rock fascia. Existing stormwater sewers inletting into the Ala Wai Canal would be modified so that fourteen would be drainage structures and 59 would be retrofitted with flap gates. Eleven road closure structures would be constructed: (1) King Street (Manoa-Palolo Canal right descending bank), (2) King Street (Manoa-Palolo Canal left descending bank), (3) Kapiolani Boulevard (Manoa-Palolo Canal right descending bank), (4) Kapiolani Boulevard (Manoa-Palolo Canal left descending bank), (5) Date Street (near the Date Street and Laau Street junction), (6) Date Street (near the vicinity of the Kaimuki High School's discus and shot put throwing area, (7) Ala Wai Golf Course Maintenance Facility driveway, (8) Ala Wai Golf Course Drive, (9) McCully Street (Ala Wai Canal right descending bank), (10) McCully Street (Ala Wai Canal left descending bank), (11) Kalakaua Avenue (Ala Wai Canal right descending bank), and (12) Kalakaua Avenue (Ala Wai Canal left descending bank). The typical cross section of this feature varies along the alignment, but all are assumed to be 6 ft above ground. The floodwall along the Ala Wai Canal and the lower right descending bank of the Manoa-Palolo Canal will include an elevated walking path. On the left descending bank of the Manoa-Palolo Canal and near Kaimuki High School, there will be a floodwall on macropiles with no walking path. Where space is constricted, along the upper right descending bank of the Manoa-Palolo Canal, tieback I-walls will be constructed, with no walking path. The purpose of the Ala Wai Canal Floodwall system would be to reduce the risk of flooding within the McCully-Moiliili neighborhood, Diamond Head neighborhood, and Waikiki.

Mitigation Measures – Mitigation measures related to induced flooding include potentially adding permanent pump station(s) of moderate to large size, ranging from 500 to 20,000 cfs. At the time of compiling this Draft Report, it is unknown as to the number of pumps that may be necessary to minimize induced flooding, the size of the pumps, or the location of pumps within the watershed. If Alternative 5.3 moves forward, additional analysis would be conducted during the Preconstruction Engineering and Design (PED) phase to determine the above and appropriate supplemental NEPA analysis and coordination would be conducted as necessary. In addition to considering pumps as potential mitigation for induced flooding within the watershed, nonstructural measures such as dry/wet floodproofing, elevation, and acquisition are also under consideration. Similar to the above, if Alternative 5.3 moves forward, additional analysis would be conducted during PED to determine the precise number and location of structures recommended for dry/wet floodproofing, elevation, or acquisition. Appropriate supplemental NEPA analysis and coordination would be conducted as necessary.

Alternative 6 (Standalone Nonstructural Plan)

Alternative 6 consists of floodproofing and elevation of approximately 1,544 structures—43 to be elevated and 1501 with dry floodproofing—within three separate reaches with positive NED benefits. Structures within the 1% AEP floodplain in reaches AW1 (953) and AW2R (542) would be elevated or floodproofed to the 1% AEP flood stage (see Figure 3 for location of each reach). Structures within the 2% AEP floodplain in reach AW7R (49) would be elevated or floodproofed to the 2% AEP flood event. The target stage for all reaches is the 1% AEP flood event. Dry floodproofing involves sealing flood prone structures from water with door and window barriers, small scale rapid deployable floodwalls, or sealants. Dry floodproofing is generally feasible and effective up to a maximum height of three feet above ground level. Floodproofing is only recommended for non-residential structures, such as commercial buildings and critical infrastructure that cannot be elevated due to their large size. Elevation of structures is limited to residential structures, largely single-family homes. Whether a structure may be elevated depends on several factors including the foundation type, size of the structure, condition, etc. Elevating a home raises the finished floor elevation to a height where it is less likely that the structure and/or contents will be damaged by flooding. Residential structures can be raised up to 12 feet above ground level but cannot be raised beyond that height due to structural constraints and wind loading concerns.

Figure 3: Targeted Reaches for Alternative 6.

2.5 Plan Evaluation

2.5.1 Federal Objective

As specified in the USACE Planning Guidance Notebook (ER 1105-2-100), the federal objective of water and related land resources planning is to contribute to national economic development (NED) consistent with protecting the Nation's environment, pursuant to national environmental statutes, applicable Executive orders (eOs), and other federal planning requirements. To demonstrate consistency with the federal objective, the effects of a project must be analyzed to demonstrate that the project benefits outweigh the costs within the context of the NED account. The NED account displays changes in the economic value of the national output of goods and services.

2.5.2 Contribution to Objectives and Avoidance of Constraints

Contributions to Objectives:

Objective 1. Reduce risks to life and safety associated with direct inundation of structures (residential, non-residential, and critical facilities) and transportation infrastructure due to riverine flooding along Makiki, Manoa, and Palolo streams and the interplay between riverine and storm surge flooding along the Ala Wai Canal over the period of analysis. Alternative 0 (No Action) would not result in a reduction to life safety risk. Alternative 1 and Alternative 2B are

expected to slightly induced life safety risk in the study area through induced flooding. Alternative 5 is expected to marginally decrease life safety risk. Alternative 6 is expected to have negligible effects on life safety risk.

Objective 2. Reduce economic damages associated with direct inundation of structures (residential, non-residential, and critical facilities) & public infrastructure due to riverine flooding along Makiki, Manoa, and Palolo streams and the interplay between riverine and storm surge flooding along the Ala Wai Canal over the period of analysis. Alternatives 1, 2B, 5, and 6 all reduce economic damages throughout the study area. Alternative 0 would not result in a reduction in economic damages, and damages could increase without federal action due to the effects of climate change and sea level rise on riverine flood risk.

Objective 3. Reduce economic impacts associated with disruption of commerce and tourism due to riverine flooding along Makiki, Manoa, and Palolo streams and the interplay between riverine and storm surge flooding along the Ala Wai Canal over the period of analysis. Alternatives 1, 2B, 5, and 6 are all expected to reduce impacts to commerce and tourism within the study area. Alternatives 1, 2B, and 5 are expected to reduce risk and economic impacts to commercial areas, including along Manoa Stream and along the Ala Wai Canal. Alternative 6 would include floodproofing of commercial facilities along the Manoa Stream and Ala Wai Canal. Alternative 0 would not result in a reduction in impacts to commerce and tourism, and impacts could increase without federal action due to the effects of climate change and sea level rise on riverine flood risk.

Avoidance of Constraints
The only study-specific constraint is that inducing further development within the floodplain cannot be included as a goal of the project. Alternatives 1, 2B, 5, and 6 all satisfy this constraint. Essentially all developable space within the floodplain has already been developed.

2.5.3 PR&G Criteria

Alternatives were also evaluated based on the four evaluation criteria outlined in the USACE Principles, Requirements, and Guidelines (PR&G) (USACE, 2013) and defined and described below:

Completeness: The extent to which the measure provides and accounts for all necessary investments or other actions to ensure the realization of the planned effects. Alternatives 0, 1, 2B, 5, and 6 represent complete alternatives in that they account for all necessary investments and actions (including potential mitigation measures described above) required to ensure realization of the planned effects. However, floodproofing and structure elevation are voluntary and participation rate could affect overall benefits accrued by each alternative.

Effectiveness: The extent to which each measure would alleviate the specified problems and achieves the specified opportunities. Alternatives 1, 2B, 5, and 6 are effective at addressing the identified problems and realizing the identified opportunities; albeit the extent to which each alternative is effective varies drastically. Alternatives 1, 2B, 5, and 6 reduce economic damages and provide $22.7M, $39M, $52.3M, and $32.4M in average annual benefits, respectively. These benefits are associated with residential, commercial/industrial facilities, and public facilities, thus, each alternative would benefit private residences, industry and commerce, and the local government. Alternative 5 is the only alternative which is expected to reduce life safety risk associated with direction inundation of occupied residential, commercial, industrial, and public structures. Alternatives 1 and 2B are expected to slightly induce life safety risk through induced flooding. Alternative 6 is expected to result in minor reductions in life safety due to

decreases in the number of structures experiencing first floor flooding and associated damages. Alternative 0 would have no effect on economic damages or life safety risk.

Efficiency: The extent to which each alternative is a cost-effective means of alleviating the specified problems and realizing the specified opportunities, consistent with protecting the Nation's environment. Alternatives 1, 2B, 5, and 6 are all cost-effective, as assessed by having positive net economic benefits and a BCR that is higher than 1.0. Specifically, the net annual economic benefits for Alternatives 1, 2B, 5, and 6 are $13.6M, $18.7M, $30.6M, and $14M, respectively, and the BCRs for each alternative are 2.5, 1.9, 2.4, and 1.76, respectively. Alternative 0 would not result in any cost or associated benefits. None of the alternatives would have a significant impact on the Nation's environment. A detailed analysis of environmental effects is presented in Chapter 3 of this report.

Acceptability: The viability and appropriateness of an alternative from the perspective of the nation's general public and consistency with existing federal laws, authorities, and public policies. Alternatives 0, 1, 2B, 5, and 6 would be acceptable in that they are all compatible with existing laws, regulations, and policies. All alternatives have the potential to garner some level of public controversy.

Environmental Effects. Effects on aquatic (stream, wetland) and terrestrial (riparian, upland, critical) habitats, water quality, and threatened/endangered species. Environmental effects of each alternative are presented in detail in Chapter 3 of this report. Alternatives 0, 1, 2B, 5, and 6 do not have significant impacts to aquatic or terrestrial habitats, water quality, or threatened and endangered species. Any environmental impacts would be minor and temporary.

A summary of the evaluation of the final array of alternatives is presented below in Table 5.

Table 5: Summary of Evaluation Criteria for Final Array of Alternatives

Evaluation Criteria	Alt. 0 (No Action)	Alt. 1 (Storage Plan)	Alt. 2B (Conveyance Plan)	Alt 5. (Hybrid Plan)	Alt 6. (Nonstruct. Plan)
Efficiency	No effect	Positive effect	Positive effect	Positive effect	Positive effect
Effectiveness (Economic Damages)	No effect	Positive effect	Positive effect	Positive effect	Positive effect
Effectiveness (Life Safety)	No effect	Negative effect	Negative effect	Positive effect	Positive effect
Effectiveness (Comm./Tour.)	No effect	Positive effect	Positive effect	Positive effect	No effect
Acceptability	No effect	Positive effect	Positive effect	Positive effect	Positive effect
Completeness	Positive effect	Positive effect	Positive effect	Positive effect	Positive effect
Environmental Effects	No significant effect	No significant effect	No significant effect	No significant effect	No significant effect

2.5.4 System of Accounts

The USACE planning process incorporates four accounts to facilitate the display and comparison of the beneficial and adverse effects of each alternative plan. The mode of analysis,

commonly referred to as the "System of Accounts," displays the positive and negative effects of broad categories of impacts in a tabular format. The accounts include those that relate to contributions to NED, Environmental Quality (EQ), Regional Economic Development (RED), and Other Social Effects (OSE). As previously described, the NED account displays changes in the economic value of the national output of goods and services. The EQ account displays the beneficial and adverse effects of the plans on ecological, cultural, and aesthetic resources. The RED account displays changes in the distribution of regional economic activity (e.g., income and employment). The OSE account displays plan effects on social aspects such as community impacts, health and safety, and recreational opportunities.

Table 6 outlines the definitions and analyses, along with the associated metrics, used to assess benefits across the four accounts described in PR&G (USACE, 2013).

Table 6: The Four Accounts.

Account	Definition	Analysis/Metrics
National Economic Development (NED)	The NED account represents the change in the economic value of the national output of goods and services that result from each alternative.	The NED account was assessed using the Hydrologic Engineering Center's Flood Damage Reduction Analysis (HEC-FDA) software. Metrics include net annual economic benefits and BCR.
Regional Economic Development (RED)	The RED account characterizes changes in the distribution of regional economic activity that result from each alternative.	The USACE Regional Economic System (RECONS) was used to estimate regional economic impacts and contributions associated with the various alternatives. Metrics include increases in employment and labor income.
Other Social Effects (OSE)	The OSE account characterizes effects that are relevant to the planning process but not reflected in the other three accounts.	Qualitative assessment of effects on life safety risk. Qualitative assessment of benefits to resiliency, social vulnerability, and community cohesion within reaches identified as socially vulnerable using the Center for Disease Control's (CDC's) Social Vulnerability Index (SVI).
Environmental Quality (EQ)	The EQ account characterizes non-monetary effects (positive or negative) on significant natural and cultural resources that result from each alternative.	Qualitative analysis that considers benefits to aquatic and riparian habitats and downstream water quality.

A summary of how each alternative contributes to the four accounts is provided in the following sections and is summarized in Table 7.

NED. Alternatives 1, 2B, 5, and 6 would contribute to the National economy, having positive net economic benefits and positive BCRs. There would be no benefit to the National economy under Alternative 0.

RED. Alternatives 1, 2B, 5, and 6 would contribute to the regional economy by supporting both regional employment and labor income. There would be no benefit to the regional economy under Alternative 0.

EQ. Environmental effects of each alternative are presented in detail in Chapter 3 of this report. In general, none of the alternatives are expected to have significant impacts to aquatic or terrestrial habitats, water quality, or threatened and endangered species. Any impacts would be minor and temporary. Environmental resources would continue to be degraded due to flooding under Alternative 0.

OSE. Alternatives 5 is expected to reduce life safety risk associated with direct inundation of occupied residential, commercial, industrial, and public structures. Alternative 6 is also expected to result in minor reductions in life safety due to decreases in the number of structures experiencing first floor flooding and associated damages. Alternatives 1 and 2B are expected to marginally elevated life safety risk further by inducing flooding. Alternative 0 would have no effect on life risk throughout the study area.

Alternatives 1 and 5 are expected reduce economic damages and life safety risk within socially vulnerable communities (i.e., communities identified as socially vulnerable by the Environmental Protection Agencies Environmental Justice Screening Tool and/or the Council on Environmental Quality Climate & Economic Justice Screening Tool). Alternative 2B would induce flooding in communities identified as socially vulnerable. Alternative 6 is expected to have no significant impact of socially vulnerable communities. Alternative 0 would have no effect on communities identified as socially vulnerable.

Table 7: Summary Table Evaluation of Alternatives–- Four Accounts.

Account	Alt. 0 (No Action)	Alt. 1 (Storage Plan)	Alt. 2B (Conveyance Plan)	Alt 5. (Hybrid Plan)	Alt 6. (Nonstruct. Plan)
NED	No effect	Positive effect	Positive effect	Positive effect	Positive effect
RED	No effect	Positive effect	Positive effect	Positive effect	Positive effect
OSE	No effect	Negative effect	Negative effect	Positive effect	No significant effect
EQ	No effect	No significant effect	No significant effect	No significant effect	No significant effect

2.5.5 Risk and Uncertainty

Risk and uncertainty are fundamental to all water resource planning and communication, and each aspect of a flood risk assessment must account for risk and uncertainty. USACE risk assessment procedures were followed in this study to account for uncertainty in the information to the extent practicable. However, there is some project performance uncertainty in all studies, even with the risk assessment procedures. This study incorporated risk management framework principles and risk-informed planning into the plan formulation process. Specific examples include the following:

- Risk analysis and communication was conducted, consistent with ER 1105-2-101, Risk Analysis for Flood Damage Reduction Studies, and EM 1110-2-1619, Risk-Based Analysis for Flood Risk Management Studies.

- The PDT incorporated risk-informed decision making into the planning process. An internal document (referred to as the risk register) was developed and used to document and carry forward those risk management concepts. Risks that were identified included unknowns that will be addressed in more detail during future design efforts, for example field investigations of geotechnical information, cultural resources, and biological resources, and updated of available information about construction costs. Subsequent technical, agency, and public reviews aid in identifying and assessing the relative risks associated and identify ways to reduce them to acceptable levels. Opportunities for value engineering will be incorporated as well to reduce the risks of missed opportunities for identifying more effective, more cost-efficient project features, designs, and/or construction.

- Uncertainty will be captured through cost engineering's mandatory cost and schedule risk assessment (CSRA) process to establish cost contingencies. The economic analysis developed ranges of economic outputs with mid and mean number ranges to best capture uncertainties and identify risks in the risk register.

- Risk and uncertainty ranges were iteratively refined for costs and economics with each subsequent level of design. This analysis confirmed the conceptual numbers were still within the established ranges of uncertainty, validating assumptions and risk decisions.

Residual Risk

Residual risk represents existing, future, or historical risk that remains or might remain after an alternative has been implemented. Every alternative in the Final Array of Alternatives would have residual risk of inundation and associated residual life safety risk. Table 8 summarizes the residual risk of each alternative in the Final Array of Alternatives, should they be implemented. Residual economic risk is presented in Fiscal Year (FY) 2023 price levels and annualized values use an FY23 federal discount rate of 2.5%. Residual Life safety risk is presented as increases, decreases, or no change from the existing and future without-project conditions (FWOPC).

Table 8: Summary of Residual Risk for Final Array of Alternatives.

Residual Risk	Alt. 0 (No Effect)	Alt. 1 (Storage Plan)	Alt. 2B (Conveyance Plan)	Alt 5. (Hybrid Plan)	Alt 6. (Nonstruct. Plan)
Economic Risk (Residual Damages)	$70.0M	$67.5M	$50.9M	$42M	$68.4M
Life Safety Risk	No change	Marginal increase from without-project condition	Marginal increase from without-project condition	Marginal decrease from without-project condition	No significant change from without-project condition

Uncertainty

Identifying and managing risk is critical to making informed planning decisions in the face of uncertainty. However, some level of uncertainty will remain following any decision. Understanding and characterizing this remaining uncertainty is also critical as it can affect the

outcome of any decision. This section characterizes remaining uncertainty under each alternative.

Uncertainty remains regarding the necessary mitigation required for potential induced damages under Alternatives 1, 2B, and 5. Contested litigation surrounding the Ideker Farms, Inc. et al. vs. the United States of America has the potential to change mitigation requirements related to induced flooding; however, the case is still being adjudicated and a final ruling is pending.

Uncertainty also remains with respect to how Alternatives 1, 2B, and 5 may affect, or be affected by, interior drainage. A full interior drainage analysis was not conducted as part of the Ala Wai Canal General Reevaluation Study and will be conducted during preconstruction engineering and design. Modifications to management measures included in each alternative and/or additional features may need to be added to each alternative to address risk associated with interior drainage.

Alternative 6 has a large degree of uncertainty pertaining to the participation rate of the proposed nonstructural measures. This alternative consists entirely of management measures with voluntary participation. Participation rates could affect the overall benefits achieved by each alternative and the amount of residual risk following implementation. Alternatives 6 is based on visual surveys and existing data, including first floor elevations. Additional information and data obtained during subsequent projects phases could result in additional structures being incorporated or current structures being removed from each alternative.

Chapter 3: Existing, Future Without Project Conditions, and Environmental Effects & Consequences

This chapter provides the existing conditions (a baseline), as well as a forecast of the Future Without Project (FWOP) conditions. The existing conditions provide a description of the human environment, which is subdivided into the natural, physical, economic, and built environments. The 2017 Ala Wai Canal Flood Risk Management Feasibility Study with Integrated Environmental Impact Statement (IFR/EIS) (USACE, 2017) is a reference for detailed information on resource categories within the study area that are discussed in this Chapter. Therefore, the 2017 Ala Wai Canal Flood Risk Management IFR/EIS (USACE, 2017) is hereby incorporated by reference, as per 40 CFR 1502.21. The following resource category descriptions within this Chapter provide brief overviews of the existing condition of resources within the study area as well as any updates to information since 2017.

This chapter also includes environmental consequences of the proposed project upon the existing environment. The environmental impacts were assessed following the 1978 Council for Environmental Quality (CEQ) Regulations. USACE took into consideration context and intensity in determining potential impact significance, as defined in 40 CFR part 1508.27 (CEQ, 1978). The intensity of a potential impact is the impact's severity and includes consideration of beneficial and adverse effects, the level of controversy associated with a project's impacts on human health, whether the action establishes a precedent for future actions with significant effects, the level of uncertainty about project impacts and whether the action threatens to violate federal, state, or local laws established for the protection of the human and natural environment. The severity of an environmental impact is characterized as none/negligible, less than significant, significant, or beneficial. The impact may also be short-term or long-term in nature.

- **None/Negligible** – This effect would cause no discernible change in the environment as measured by the applicable significant criteria; therefore, no mitigation would be required.
- **Less than Significant** – This effect would cause no substantial adverse change in the environment as measured by the applicable significance criteria; in general, no mitigation would be required (but in some cases may be incorporated as a best practice or to meet other regulatory requirements).
- **Significant** – This effect would cause a substantial adverse change in the physical conditions of the environment or as otherwise defined based on the significance criteria. Effects determined to be significant fall into two categories: those for which there is feasible mitigation available that would avoid or reduce the environmental effects to less-than-significant levels, and those for which there is either no feasible mitigation available or for which, even with implementation of feasible mitigation measures, there would remain a significant adverse effect on the environment. Those effects that cannot be reduced to a less-than-significant level by mitigation are identified as significant and unavoidable.
- **Beneficial** – This effect would provide benefit to the environment as defined for that resource.
- **Direct** – An effect on a resource by an action at the same place and time.
- **Indirect** – An effect from an action that occurs later or possibly at a different place and often to a different resource but is still reasonably foreseeable.
- **Short-term** – Temporary in nature and does not result in permanent long-term beneficial or adverse effect to a resource. For example, temporary construction-related effects (such as, an increase in dust, noise, traffic congestion) that no longer occur once construction is complete. May be minor, significant, adverse, or beneficial in nature.

- **Long-term** – Permanent (or for most of the project life) beneficial or adverse effects to a resource. For example, permanent conversion of a wetland to a parking lot. May be minor, significant, adverse, or beneficial in nature.

The USACE used quantitative and qualitative analysis, as appropriate, to determine the level of potential impact from proposed alternatives. Based on the results of the analyses, this SEIS identifies whether a particular potential impact would be adverse or beneficial, and to what extent. CEQ Regulations (1978) also require that a proposed action's cumulative impact be addressed as part of a NEPA document. Cumulative impacts are discussed in Section 3.7.

Like the existing conditions, the 2017 Ala Wai Canal Flood Risk Management Study IFR/EIS (USACE, 2017) detailed the effects of proposed measures on the human environment that are included in the current effort. Table 9 shows the measures from the 2017 study that are still being considered for implementation as part of the current effort as well as measures that were not part of the 2017 study but are part of the current effort. The measures that are the same as the 2017 study have already been evaluated in the 2017 IFR/EIS will be analyzed in the impact analysis below.

Table 9: Comparison of Included Measures for the 2017 Recommended Plan and the 2023 GRR Alternatives.

Measures	2017 IFR/EIS Recommended Plan	2023 GRR Alternative 1	2023 GRR Alternative 2B	2023 GRR Alternative 5.3[1]	2023 GRR Alternative 6

[1] Alternative 5.3 is the same as Alternative 5, but optimized. Because Alternative 5.3 is the Tentatively Selected Plan, the potential environmental impacts of the optimized alternative are analyzed in this Chapter 3.

3.1 Period of Analysis

The period of analysis is 50 years.

3.2 General Setting

The Ala Wai Watershed is located on the island of Oahu, which has undergone major land-use changes in the past 100 years. Since 1950 the resident population of the island has more than doubled (State of Hawaii, 2000). Honolulu, the capital city located on the island of Oahu, is now considered the most densely populated city in the Nation (Fulton et al., 2001). Urbanization on Oahu has been accompanied by substantial alterations to stream systems, including changes in water quality, instream habitat, riparian habitat, and the introduction of nonnative species. An extensive study conducted in the 1970s, showed that 57% of the streams on the island of Oahu had been channelized, 58% had water exported from them, and all had roads crossing over them (Timbol and Maciolek, 1978). Modifications of the stream ecosystems have been most severe at the lower elevations where urban growth is greatest (Timbol and Maciolek, 1978). Artificially straightened reaches with concrete-lined flat-bottomed channels and revetted (reinforced) banks are common in the urban areas of the study area. Such modifications are commonly accompanied by removal of riparian vegetative cover, and a reduction in substrate complexity (removal of large boulders).

3.3 Physical Environment

3.3.1 Climate and Climate Change

Regulatory Setting

No federal regulations regarding climate change apply to the study area. The U.S. Environmental Protection Agency (USEPA) has started the process of regulating large sources of greenhouse gas (GHG) emissions (e.g., power plants, cement manufacturing, etc.), but these proposed regulations are not applicable to the study area. Hawaii laws that address climate change include:

- Act 234 (State Legislature Hawaii [SLH] 2007)
- Act 286 (Hawaii Revised Statutes [HRS] § 226-109), *Climate Change Adaptation Priority Guidelines*
- Act 83 (HRS Chapter 225P), *Hawaii Climate Adaptation Initiative Act*

Existing Conditions

The climate of the study area is characterized by mild temperatures, which vary little between seasons. The small temperature difference between the warmest and coolest months is largely attributable to the influence of the surrounding ocean, the persistence of cool trade winds, and the small seasonal variation in solar radiation (Blumenstock and Price, 1967; Sanderson, 1993). Daylight hours also change little from season to season. The length of the longest day and the shortest day of the year vary only by a few hours. The rainy season occurs from October through April and a dry season occurs from May through September; however, high rains and storm flows can occur throughout any given year. During heavy storms, 24-hour rainfall can exceed 10 inches over coastal areas and 20 inches over mountainous areas (Giambelluca et al., 1984).

The Pacific region is subject to various patterns of climate variability (USGCRP, 2018). The effects of the El Niño-Southern Oscillation (ENSO) and other patterns of oceanic and atmospheric variability in the region are significant. They include large variations in sea surface temperatures, the strength and persistence of the trade winds, the position of jet streams and

storm tracks, and the location and intensity of rainfall. The ENSO-related extremes of El Niño and La Niña generally persist for 6 to 18 months and change phase roughly every 3 to 7 years. The Pacific Decadal Oscillation (PDO) and the Interdecadal Pacific Oscillation (IPO) are patterns that operate over even longer time horizons and include the weather and climate of the region. Even after accounting for these natural patterns, the waters around Hawaii have been warming since the 1950s, with temperatures from the surface to a depth of 660 feet rising by as much as 3.6°F. If emissions continue to increase, future sea surface temperatures are projected to increase 1.7°F by 2030, 2.3°F by 2055, and 4.7°F by 2090 (USGCRP, 2018).

The future trend for precipitation within Hawaii is uncertain currently (USGCRP, 2018). For nearly a century, the average precipitation, average stream discharge, and stream baseflow have been trending downward for Hawaii. However, there is high variability due to the cyclical patterns described above (i.e., ENSO, PDO, and IPO) and there is uncertainty as to whether this trend will continue. In addition, while rainfall in Hawaii generally has been decreasing, it is also becoming more extreme. Both extreme heavy rainfall events (causing increased runoff, erosion, and flooding) and droughts (causing water shortages) have become more common. The number of consecutive wet days and the number of consecutive dry days are both increasing in Hawaii (USGCRP, 2018).

Surface air temperatures within the region have increased and are expected to continue to rise over the entire region (USGCRP, 2018). In Hawaii, the rate of increase has been greater at high elevations. If emissions continue to increase, projected annual surface air temperature is expected to increase 3.5°F by 2055. On most islands, increased temperatures coupled with decreased rainfall and increased drought will reduce the amount of freshwater available (USGCRP, 2018).

Regarding sea level change, global mean sea level rose at a rate of 0.047 $\pm$ 0.008 inches (in) per year (yr) from 1993 to 2016, and that rate accelerated to 0.134 $\pm$ 0.016 in/yr (Nerem et al., 2010). The semi-diurnal tide range in Honolulu is about 1.903 feet and the rate of sea level rise is about 0.056 + 0.008 in/yr, based on Honolulu tide station from 1905-2015 (NOAA, 2017). Church et al. (2013) estimates that global mean sea level could rise to 3.215 feet by 2100. Others, such as Sweet et al. (2017) suggest that sea level could rise by 6.562 feet in the Hawaii region by 2100. Flooding from sea level rise is anticipated to increase in frequency and intensity in the coming decades and it is anticipated that Honolulu will encounter as many as 100 tidal floods per year (Thompson et al., 2019). It is suggested that coastal groundwater will play a significant role in contributing to flooding in Honolulu through marine inundation (Rotzoll and Fletcher, 2013). A byproduct of marine inundation will be the infiltration of marine waters backing up into sewer mains and storm drain systems (Habel, 2019). Onsite sewage disposal systems, a common form of sewage treatment in Hawaii, are at risk of discharging contaminated groundwater and pose a risk to public health (Whitter and El-Kadi, 2014; Balaraman, 2016).

All the climate change factors described above will have an impact on human communities in Hawaii (USGCRP, 2018). Because Hawaii is almost entirely dependent upon imported food, fuel, and material, the vulnerability of ports and airports to extreme events, sea level rise, and increasing wave heights is of great concern. Climate change is expected to have serious effects on human health and natural resources. In addition, sea level rise and flooding are expected to overwhelm sewer systems and threaten public sanitation (USGCRP, 2018).

Significance Criteria

The environmental consequences of the proposed project related to climate change are evaluated using the criteria listed below. An effect was considered significant if it would:

- Generate GHG emissions, either directly or indirectly, that may have a significant impact on the environment.
- Conflict with an applicable plan, policy, or regulation adopted for the purpose of reducing emissions of GHGs or addressing climate change.

Environmental Consequences

No Action

No Impact: Under the No Action Alternative, none of the flood risk management measures would be implemented, such that no construction equipment from implementation of the project would be used or generate GHG emissions that could have an effect on the environment. Construction of other projects (federal or non-federal), operations of other projects, and maintenance of other projects within the watershed would continue but are not expected to have a significant contribution of GHG emissions that could have an impact on the environment.

Alternative 1

Less than Significant Impact: Effects from Alternative 1 on climate change through GHG emissions produced during construction of the structural and mitigation measures and use of diesel backup generators for pump stations, if found to be necessary, would result in only slight increases in GHG emissions and be below thresholds under the present status of attainment for air quality. Therefore, the project would result in short-term less than significant adverse impacts to climate change while construction of the structural features and mitigation measures is occurring. The completed project would consist mainly of statis features that would not produce on-going GHG emissions. If pumps are implemented as a mitigation measure, the operation of those pumps during a storm event would result in only slight increases in GHG emissions. Similarly, the maintenance of the project would require functionality assessments and minor repairs as well as clean up and disposal of debris, especially within the Ala Wai Golf Course detention basin following a storm event. Maintenance activities would require the use of small construction equipment and maintenance vehicles. Therefore, the project would result in long-term less than significant adverse impacts to climate change primarily when operation of the pumps is occurring and/or maintenance activities are occurring. The consideration of GHG emissions focused on the use of heavy machinery, assumed to be fueled by diesel and/or gasoline.

Published USEPA data indicate that approximately 22 pounds of carbon dioxide are produced for every gallon of diesel fuel burned, and approximately 19 pounds are produced for every gallon of gasoline used (EPA, 2023). In 2018, the State of Hawaii used approximately 511 million gallons of fuel for ground-based transportation (HSEO, 2019), including all vehicles. The average passenger vehicle in Hawaii travels 9400 miles per year (HSEO, 2019); the island of Oahu has over 790,000 passenger vehicles registered (Honolulu Civil Beat, 2019). Construction equipment represents a relatively small fraction of petroleum use, however, compared to road vehicles such as passenger cars. The transportation industry (trucks and cars) uses approximately 77% of diesel fuel in the U.S., while the entire industrial sector (including all factories, commercial uses and construction equipment) uses approximately 13% (USEIA, 2022). In general, construction equipment emissions are a small fraction of GHG emissions.

Efforts are on-going for all equipment manufacturers to reduce emissions and increase the fuel efficiency of construction equipment. Best management practices (BMPs) can also be used to

decrease GHG emissions from diesel engines. Some BMPs that are commonly implemented on construction projects and that would be implemented on this project include:

- Minimize waiting times and idling times by staging equipment to be present and operating only when needed.
- Conduct operations in sequence and bundle work to minimize the time needed for any piece of equipment.
- Ensuring haul loads are full all legs of a round trip, instead of empty return trips.

Each individual measure in the alternative will likely be constructed as a discrete project, so that travel distances to staging areas and stockpiles can be minimized. Each individual feature would be a comparatively small and local project, without large area impacts beyond the feature footprint. Given the scale of the project, the total amount of emissions resulting from construction would be insignificant at a regional scale; further, the emission levels would be significantly under the federal reporting threshold (25,000 metric tons per year). Once constructed, the alternative would have a long-term negligible effect would have no long-term direct or indirect on-going emissions or fuel consumption. As such, Alternative 1 would be expected to have a short-term indirect less than significant effect on climate change due to GHG emissions during construction activities.

Construction of Alternative 1 and the long-term operation and maintenance associated with the alternative would not conflict with an applicable plan, policy, or regulation adopted for the purpose of reducing emissions of GHGs or addressing climate change. The purpose of Act 286 HRS § 226-109, *Climate Change Adaptation Priority Guidelines*, is "to encourage collaboration and cooperation among county, state, and federal agencies, policy makers, businesses, and other community partners to plan for the impacts of climate change and avoid, minimize, or mitigate loss of life, land, and property of future generations." Alternative 1 would meet the purpose of Act 286 by constructing flood risk management features with the objective of minimizing potential flood induced damages to property and life safety due to climate change induced flooding. Therefore, Alternative 1 would have long-term direct and indirect beneficial effects for adaptation to climate change.

Alternative 2B

Less than Significant Impact: In general, the type of project features included in Alternative 2B would have similar construction, operation, maintenance, and mitigation requirements as Alternative 1, such that the nature and degree of potential climate and climate change impacts are generally expected to be similar. Therefore, refer to the analysis under Alternative 1 for Alternative 2B project impacts. Overall, Alternative 2B would be expected to have a short-term less than significant effect on climate change due to GHG emissions during construction activities. Similarly, Alternative 2B would have a long-term less than significant effect on climate change due to GHG emissions during pump operations and maintenance activities. Alternative 2B would also be expected to have long-term direct and indirect beneficial effects for adaptation to climate change.

Alternative 5.3

Less than Significant Impact: In general, the type of project features included in Alternative 5.3 would have similar construction, operation, maintenance, and mitigation requirements as Alternatives 1 and 2B, such that the nature and degree of potential climate and climate change impacts are generally expected to be similar. Therefore, refer to the analysis under Alternatives 1 and 2B for Alternative 5 project impacts. Overall, Alternative 5.3 would be expected to have a short-term less than significant effect on climate change due to GHG emissions during

construction activities. Similarly, Alternative 2B would have a long-term less than significant effect on climate change due to GHG emissions during pump operations and maintenance activities. Alternative 5.3 would also be expected to have long-term direct and indirect beneficial effects for adaptation to climate change.

Alternative 6

Less than Significant Impact: Alternative 6 involves temporary construction on existing structures, construction access, and/or acquisition of existing structures. GHG emissions resulting from implementation of Alternative 6 would occur from the use of construction equipment necessary to elevate or demolish existing structures, as determined necessary. The GHG emissions would have a short-term less than significant adverse effect on climate change. Long-term, there would be a negligible adverse effect on climate change due to minor maintenance activities that would be required to maintain the elevated or floodproofed structures. In addition, Alternative 6 would have long-term direct and indirect beneficial effects for adaptation to climate change, as this is the purpose of these nonstructural measures. Elevation and dry/wet floodproofing would both aid in adaptation of thousands of structures to potentially significant future flooding due to climate change.

Environmental Commitments

No additional environmental commitments other than the BMPs discussed below would be implemented to minimize impacts to climate or climate change.

Best Management Practices

The following BMPs are focused on minimizing potentially adverse impacts to air quality; however, many of these BMPs would also help reduce GHG emissions. Therefore, the following BMPs would be implemented by the contractor to further reduce GHG emissions attributable to the project.

- Improve fuel efficiency from construction equipment by minimizing idling time either by shutting equipment off when not in use or reducing the time of idling to no more than five minutes. Provide clear signage that posts this requirement for workers at all entrances to a construction site.
- Maintain all construction equipment in proper working condition according to manufacturer's specifications. The equipment must be checked by a certified mechanic and determined to be running in proper condition before it is operated.
- Use equipment with new technologies when feasible (e.g., repowered engines, electric drive trains, etc.).
- Perform on-site material hauling with trucks equipped with on-road engines (if determined to be less emissive than the off-road engines).
- Encourage and provide carpools, shuttle vans, transit passes, and/or secure bicycle parking for construction worker commutes.

3.3.2 Geology, Seismicity, and Soils

Regulatory Setting

- Federal Soil Protection Act
- HRS, Title 12, Chapter 180 – *Soil and Water Conservation Districts*

Existing Conditions

The Island of Oahu is constructed from two shield volcanoes, Waianae and Koolau (Rowland and Garcia, 2004). Waianae is the older of the two volcanoes (subaerial flows are ~3.9 to ~2.8

million years old) and makes up the western part of Oahu, while Koolau is younger (subaerial flows are ~2.9 to 2.1~ million years old) and makes up the eastern part of the island (Rowland and Garcia, 2004). The Ala Wai watershed lies on the southern slope of the Koolau volcano. Erosional forces such as wind and precipitation have eroded sediment from the valleys cut into Koolau and transported these sediments oceanward where they were deposited along the south coast of Oahu. The Honolulu coastal plain, which generally extends from Pearl Harbor to Koko Head, is comprised of interlayered terrigenous and marine sediments and calcareous materials, as well as volcanic deposits produced by rejuvenated-stage volcanism (Stearns, 1935). Metropolitan Honolulu (including Waikiki) is built on these sediments. The sediments have very little bearing strength and high-rise buildings in Honolulu are therefore built on concrete piles driven through the soft sediment until they bottom out on either limestone or rejuvenation-stage lava layer.

The U.S. Department of Agriculture, Natural Resources Conservation Service's Web Soil Survey was queried for soil types present within the study area. Table 10 displays the soil types within the study area and their general characteristics.

Seismic activity around Oahu is related to tectonic activity along seafloor fractures and faults, such as the Diamond Head Fault, which extends along the seafloor northeast of Oahu (Furumoto et al., 1990). Oahu is considered relatively stable in terms of subsidence and rates of uplift have been less than 0.004 in/yr since the last interglacial period with an estimated mean of 0.002 in/yr over the last 200,000 years (Fletcher and Jones, 1996; Caccamise, 2003). Landslides have been documented within the Ala Wai watershed and involve the incremental movement of land that remains saturated over a relatively long period of time (Baum and Reid, 1992). In contrast, debris flows are the mass sliding of soil with the underlying bedrock and overtopping vegetation moving rapidly, typically down a drainage channel, potentially damaging homes and other structures located in the path.

Table 10: Characteristics of Soil Types in the Study Area (USDA-NRCS, 2022).

Soil Type	Soil Characteristics	Hydric Soil Rating	Depth to Water Table	Drainage Class	Frequency of Flooding	Farmland Classification
Ewa Silty Clay Loam, Moderately Shallo, 0 to 2 percent slopes	Found on moderately shallow footslopes	No	More than 80 inches	Well Drained	None	Prime farmland if irrigated
Fill Land, Mixed	Fill found on flats and toeslopes	No	More than 80 inches	Well Drained	Rare	Not prime farmland
Hanalei Silty Clay, 0 to 2 percent slopes	Alluvium derived from basalt and found on flood plains on valley floors	No	About 24 to 60 inches	Poorly Drained	Frequent	Not prime farmland
Kaena Very Stony Clay, 10 to 35 percent slopes	Formed in alluvium and colluvium and found on fans	No	About 24 to 60 inches	Poorly Drained	None	Not prime farmland
Kawaihapai Clay Loam, 0 to 2 percent slopes	Alluvium derived from basalt and found on drainageways on mountain slopes and drainage ways on alluvial fans	No	More than 80 inches	Well Drained	None, Occasional	Prime farmland if irrigated
Kawaihapai Stony Clay Loam, 2 to 6 percent slopes	Alluvium derived from basalt and found on drainageways on mountain slopes and drainageways on alluvial fans	No	More than 80 inches	Well Drained	Occasional	Prime farmland if irrigated
Makiki Clay Loam, 0 to 2 percent slopes	Alluvium found on alluvial fans	No	More than 80 inches	Well Drained	None	Prime farmland if irrigated
Makiki Stony Clay Loam, 0 to 3 percent slopes	Alluvium found on alluvial fans	No	More than 80 inches	Well Drained	None	Prime farmland if irrigated
Molokai Silty Clay Loam, 3 to 7 percent slopes	Residuum weathered from basalt found on hillslopes	No	More than 80 inches	Well Drained	None	Prime farmland if irrigated
Rock Land	Basalt found on pahoehoe lava flows	No	More than 80 inches	Well Drained	None	Not prime farmland
Tantalus Silty Clay Loam, 15 to 40 percent slopes	Volcanic ash found on backslopes	No	More than 80 inches	Well Drained	None	Not prime farmland

Significance Criteria

The proposed project would result in a potentially significant impact to geology, soils, and seismicity if it would:

- Cause potential substantial adverse effects, including risk of loss, injury, or death involving strong seismic ground shaking; seismic-related ground failure, including liquefaction; or landslides.
- Result in substantial soil erosion or the loss of topsoil.
- Be located on a geologic unit or soil that is unstable, or that would become unstable as a result of the project, and potentially result in on- or off-site landslide or collapse.
- Destroy a unique geologic feature.

Environmental Consequences

No Action

No Impact: Under the No Action Alternative, none of the flood risk management measures would be implemented. As no features would be constructed, there would be no project-related activities that would affect geologic, seismic, or soil conditions. The physical conditions within each of the measure locations would be expected to be generally commensurate with the current onsite conditions.

Erosional processes, including debris flows and landslides, are expected to continue across the watershed, especially in areas of potential hazard including steep slopes and high annual rainfall, as noted by Ellen et al. (1993). Given the potential for more intense episodes of rainfall, these events could potentially occur on a more frequent basis. In addition, expansion of invasive tree species (particularly those that easily uproot because of shallow root systems [such as *Miconia calvescens*]) into the steep upper slopes of the watershed could further contribute to increased frequency of mass wasting events.

Alternative 1

Less than Significant Impact with Environmental Commitments Incorporated: In terms of seismicity, the alternative footprint is located approximately 9.5 miles from the nearest fault, the Diamond Head Fault which is located along the seafloor northeast of Oahu. The alternative footprint is the physical location of an alternative and all included measures, either individually or collectively, that will be impacted to facilitate construction associated with alternative. Although no project features would be constructed over or near a fault zone, project features, including mitigation measures for induced flooding, would be located on sites with potential to experience periodic shaking, possibly of considerable intensity. This is because thousands of earthquakes occur every year in Hawaii, but most have an epicenter on or around the Island of Hawaii. Since the Island of Oahu is located northwest of the Island of Hawaii, the alternative footprint would have the potential for periodic shaking of moderate intensity with slight damage possible. However, project features, including mitigation measures for induced flooding, would follow seismic design requirements which would provide structural stability. Also, the project is not expected to draw a substantial amount of people, either during project construction activities (less than 40 construction personnel would be on site during construction) or permanently (no structures intended for human occupancy would be built; however, mitigation measures would alter existing structures with human occupancy), and only a small number of personnel would be needed for maintenance and operation activities, which are expected to be minimal. Therefore, short-term construction and long-term operation and maintenance of the project is not expected to expose people or structures to significant adverse, impacts related to fault rupture.

Regarding liquefaction, the U.S. National Earthquake Hazard Reduction Program (NEHRP) soil classes were used to assess potential for seismic amplification which in turn could cause liquefaction of soils. Under the NEHRP heirarchy, locations designated as class A soils are least susceptible to seismic amplification (i.e., least susceptible to liquefaction), while class E soils are the most susceptible to seismic amplification (i.e., most susceptible to liquefaction). As shown in Figure 4, the alternative footprint is primarily underlain by NEHRP class D and B soils with a scattering of class C soils. NEHRP class D soils are primarily prevalent in the Waikiki District of the alternative footprint, which is understandable since places in Waikiki include deep fill that is more susceptible to liquefaction. Under this alternative, there are no features proposed within the Waikiki District. Therefore, while project features, including mitigation measures for induced flooding, could be susceptible to liquefaction, most features would be located on class B soils which are on the lower end of the scale in terms of susceptibility to liquefaction. Project features, including proposed mitigation measures for induced flooding, would also follow seismic design requirements which would provide structural stability and EC GSS-1 would further reduce potential adverse impacts by following conclusions and recommendations in the Geotechnical Investigation Appendix (Appendix D). Moverover, project features would not include structures intended for human occupany; although existing structures with human occupancy could be modified as part of proposed mitigation measures for induced flooding. Operation and maintenance activities are expected to be minimal with periodic checking of the floodwalls/earthen berms, debris clearing from detention basins post storm, minor repairs to floodwalls/earthen berms after a significant storm event, minor repairs/replacement of equipment related to potential pump stations, and minor repairs to elevated/floodproofed homes. Therefore, short-term construction and long-term operation and maintenance of the project is expected to expose people or structures to less than significant adverse impacts, with environmental commitments incorporated, related to seismic-related ground failure such as liquefaction.

According to Figure 5, a majority of the alternative footprint has little potential for landslides. The Waahila Ridge within the alternative footprint is the only area with a moderate susceptibility to landslides. Project features closest to the Waahila Ridge are the Manoa Valley District Park Detention Basin (approximately 0.41 mile north of Waahila Ridge) and the Koali Road Floodwall (approximately 0.45 mile south/southwest of Waahila Ridge). Due to the distance of these sites from Waahila Ridge, construction of the project as well as long-term operation and maintenance is not expected to contribute to landslide potential or increase the risk of people or structures being exposed to landslides.

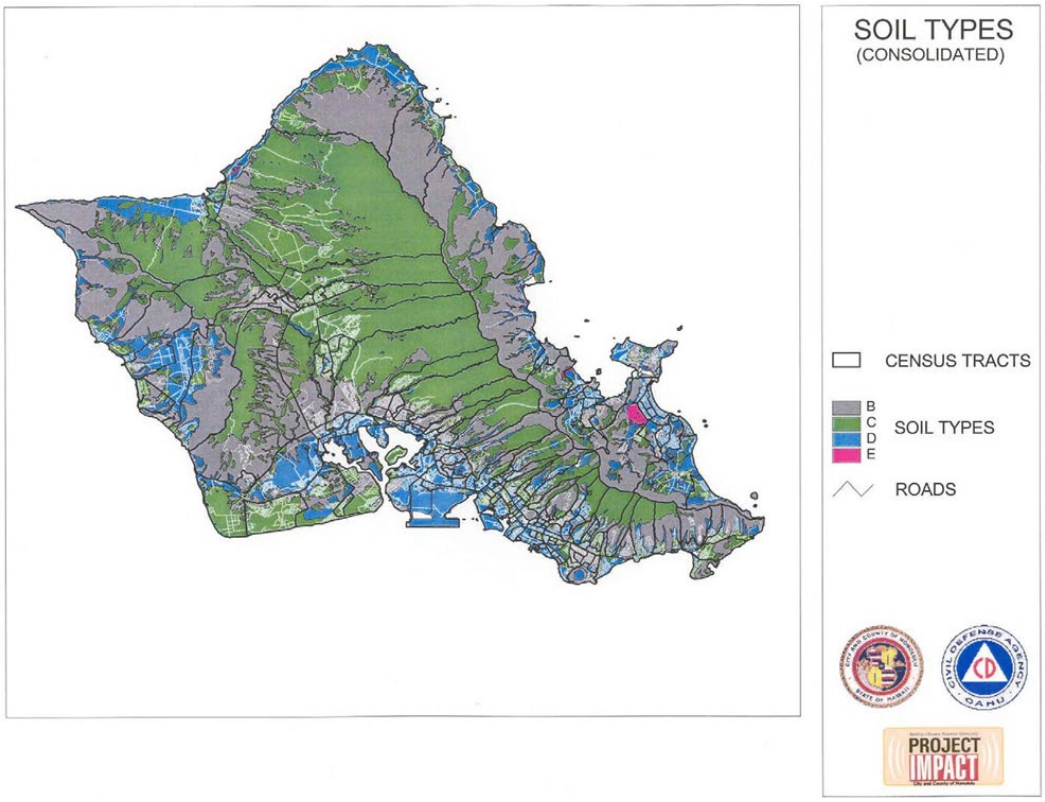

Figure 4: NEHRP Soil Types (Consolidated) within Oahu.

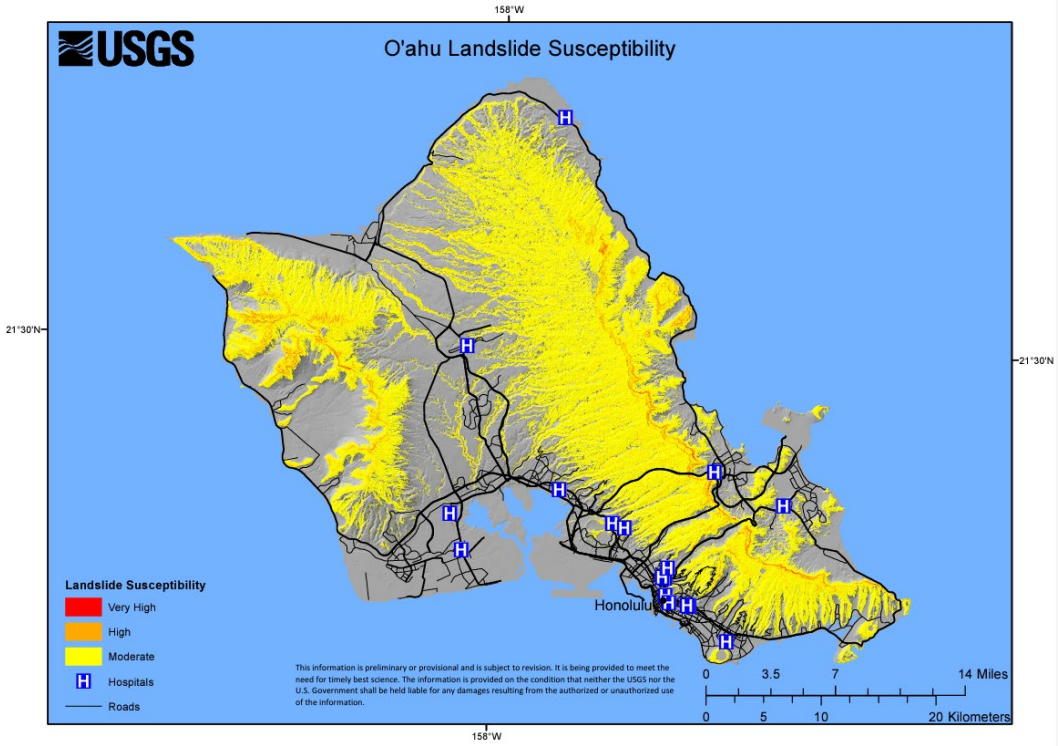

Figure 5: Potential Landslide Susceptibility for Oahu.

The project would involve excavation activities that would expose soils. The exposed soils could be subject to erosion impacts caused by water and wind. In addition, the construction of pump stations and the elevation of existing structures may involve embedment into the substrate. These potential effects on the subsurface geology would be permanent but considered to be minor based on other common residential or commercial construction projects in the area.

Alternative 1 also includes potential mitigation measures for induced flooding. Construction of pump stations and of elevating homes may involve embedment into the subsurface. These potential effects on the subsurface geology would be permanent but considered to be minor based on other common residential or commercial construction projects in the area. Overall, temporary minor adverse impacts would be expected for topography and soils, and negligible impacts on geology.

Additionally, construction equipment and vehicles could indirectly transport sediment to offsite locations. Construction projects which disturb one or more acres of soil are required to obtain coverage under a General Construction Permit. The project would disturb more than one acre and would be required to obtain a General Construction Permit. The General Construction Permit would require the filing of a Notice of Intent with the State of Hawaii, Department of Health, Clean Water Branch and the preparation of a Storm Water Pollution Prevention Plan (SWPPP). The SWPPP would provide a list of BMPs to minimize potential soil erosion impacts. Additionally, after the project is completed, where feasible disturbed areas would be established and/or reestablished with vegetation to minimize long-term erosion impacts. Therefore, potential impacts associated with erosion would be less than significant with mandatory compliance with existing regulations and procedures outlined in the General Construction Permit and implementation of a SWPPP.

Unique geologic features within the vicinity of the alternative action area include Waikiki Beach, Diamond Head, Round Top, Sugar Loaf, Tantalus, and Punchbowl (H.T. Stearns, 1939). The alternative action area includes the alternative footprint and areas outside of the the alternative footprint where indirect impacts from construction or implementation of the alternative could occur as well as the marine aquatic habitat in the Ala Wai Small Boat Harbor and the marine aquatic habitat within 1,640 feet (500 meters) of the mouth of the Ala Wai Small Boat Harbor. The closest unique geologic feature to the alternative action area would be Waikiki Beach. However, although close, none of the project features are proposed to be constructed on the above unique geologic features. Because of the information above, no short-term or long-term impacts to a unique geologic feature would occur due to implementation of the project.

Alternative 2B

Less than Significant Impact with Environmental Commitments Incorporated: In general, the type of project features included in Alternative 1 would have similar construction, operation, maintenance, and mitigation requirements as those in Alternative 2B, such that the nature and degree of impacts are generally expected to be similar. However, due to additional floodwall locations, there is the potential for a different degree of impacts specifically related to liquefaction and soil erosion. Therefore, the analysis for potential liquefaction and soil erosion impacts specific to Alternative 2B is below. Refer to the analysis under Alternative 1 for all other potential project impacts to geology, soils, and seismicity from Alternative 2B.

Regarding liquefaction, as shown in Figure 4, the alternative footprint is primarily underlain by NEHRP class D and B soils with a scattering of class C soils. NEHRP class D soils are primarily prevalent in the Waikiki District of the alternative footprint, which is understandable since places in Waikiki include deep fill that is more susceptible to liquefaction. Under this alternative, there

would be a floodwall constructed on the left and right descending banks of the Ala Wai Canal from Manoa-Palolo Canal downstream to Ala Moana Boulevard. Since the Ala Wai Canal floodwall could be constructed on top of NEHRP class D soils, the project feature is susceptible to liquefaction. However, it is important to distinguish that the construction of the floodwall would not be expected to cause liquefaction of soils. In addition, project features would follow seismic design requirements which would provide structural stability and EC GSS-1 would further reduce potential impacts by following conclusions and recommendations in the Geotechnical Investigation Appendix (Appendix D). For long-term operation and maintenance, there is the possibility that the floodwall could experience subsidence from earthquakes causing soils to liquefy in the Waikiki area. However, the floodwall does not include structures intended for human occupancy and the floodwall would follow seismic design requirements which would be provide structural stability. Therefore, short-term construction and long-term operation and maintenance of the project is expected to have a less than significant impact, with environmental commitments incorporated, regarding exposer of people or structures to significant impacts related to seismic-related ground failure such as liquefaction.

The project would involve excavation activities that would expose soils. In addition, the construction of pump stations and the elevation of existing structures may involve embedment into the substrate. These potential effects on the subsurface geology would be permanent but considered to be minor based on other common residential or commercial construction projects in the area.

Alternative 2B also includes potential mitigation measures for induced flooding. Construction of pump stations and elevation of homes may involve embedment into the subsurface. These potential effects on the subsurface geology would be permanent but considered to be minor based on other common residential or commercial construction projects in the area. Overall, temporary minor adverse impacts would be expected for topography and soils, and negligible impacts on geology.

Additionally, construction equipment and vehicles could indirectly transport sediment to offsite locations. Construction projects which disturb one or more acres of soil are required to obtain coverage under a General Construction Permit. The project would disturb more than one acre and would be required to obtain a General Construction Permit. The General Construction Permit would require the filing of a Notice of Intent with the State of Hawaii, Department of Health, Clean Water Branch, and the preparation of a Storm Water Pollution Prevention Plan (SWPPP). The SWPPP would provide a list of BMPs to minimize potential soil erosion impacts. Additionally, after the project is completed, where feasible disturbed areas would be established and/or reestablished with vegetation to minimize long-term erosion impacts. Long-term, the operation of the project could increase erosion of stream banks within the Ala Wai watershed since Alternative 2B would increase conveyance of stormwaters through the system and out through the Ala Wai Small Boat Harbor. Long-term maintenance activities would include monitoring of the project features as well the stream banks for impacts. Any erosion of the stream banks caused by project features could be repaired. Therefore, potential impacts associated with erosion would be less than significant with mandatory compliance with existing regulations and procedures outlined in the General Construction Permit and implementation of a SWPPP.

Alternative 5.3

Less than Significant Impact with Environmental Commitments Incorporated: In general, the type of project features included in Alternative 5.3 would have similar construction, operation, maintenance, and mitigation requirements as those in Alternative 1 and Alternative

2B, such that the nature and degree of impacts are generally expected to be similar. Therefore, refer to the analysis under Alternative 1 and Alternative 2B for Alternative 5.3 project impacts.

Alternative 5.3 also includes potential mitigation measures for induced flooding. Construction of pump stations and of elevating homes may involve embedment into the subsurface. These potential effects on the subsurface geology would be permanent but considered to be minor based on other common residential or commercial construction projects in the area. Overall, temporary minor adverse impacts would be expected for topography and soils, and negligible impacts on geology.

Alternative 6

Less than Significant Impact: Alternative 6 involves temporary construction on existing structures, temporary construction access, and/or acquisition of existing structures. This would require the short-term use of heavy equipment, trucks, building materials such as lumber and jacks. There would be minor direct adverse effects to soils during construction; the preparation of a SWPPP would provide a list of BMPs to minimize potential soil erosion impacts. Long-term, there could be minor beneficial effects on soils since following construction disturbed areas would be reshaped if necessary for drainage and stabilization and seeded.

Environmental Commitments

Implementation of the environmental commitment listed below, would reduce to the extent feasible, impacts to geological resources and soils within the alternative footprint.

EC GSS-1: During construction activities, the project applicant shall incorporate the conclusions and recommendations included in the Geotechnical Investigation Appendix. Geotechnical conclusions and recommendations are in Appendix D and discuss geologic hazards such as slope stability, liquefaction, settlement potential, soil suitability, soil corrosivity, etc.

Best Management Practices

The following standard BMPs would be implemented by the contractor of by USACE to avoid or minimize any effects of potential erosion. Implementation of these BMPs would ensure that effects from erosion would remain at less than significant levels.

- Appropriate erosion control measures would be incorporated into the SWPPP to prevent sediment from entering waterways. The contractor would use a water truck or other appropriate measures to control fugitive dust on haul roads, construction areas, and stockpiles.
- Disturbed areas slated for revegetation would be planted in a timely manner to control erosion.

3.3.3 Air Quality

Regulatory Setting

Relevant federal and state laws/regulations include:

- Clean Air Act
- General Conformity Rule
- Department of Health, Public Health Regulations, Chapter 43, Air Pollution Control Regulations
- Department of Health, Title 11, Chapter 60, Air Pollution Control Regulations

- Department of Health, Title 11, Chapter 60.1, Air Pollution Control, Hawaii Administrative Rules
- Non-Road Diesel Fuel Rule
- Emissions Standards for On-Road Trucks
- Environmental Protection Agency Diesel Fuel Rule
- Off-Road Diesel Engine Rule

Existing Conditions

The federal Clean Air Act requires the U.S. Environmental Protection Agency (USEPA) to set national ambient air quality standards (NAAQS) for six criteria pollutants (i.e., carbon monoxide, lead, nitrogen dioxide, particulate matter, ozone, and sulfur oxides) which are considered harmful to public health and the environment. Areas not meeting the NAAQS for one or more of the criteria pollutants are designated as "nonattainment" areas by the USEPA. According to the USEPA Green Book, the study area does not fall within or near any designated non-attainment areas for any criteria pollutants (USEPA, 2022a).

Significance Criteria

Effects to air quality would be considered significant if the proposed project would result in any of the following:

- Exceed federal or State air quality standards established for criteria pollutants.
- Substantially contribute to an existing exceedance of a federal or State air quality standard (for pollutants in non-attainment).
- Expose sensitive receptors to substantial pollutant concentrations.
- Result in other emissions (such as those leading to odors) adversely affecting a substantial number of people.

Environmental Consequences

No Action

No Impact: Under the No Action Alternative, no federally funded flood risk management improvements would be implemented, such that no emissions of criteria pollutants would occur. The existing range of air pollution sources within the project area would not be expected to change substantially over the period of analysis. With continuing trade wind patterns, air quality levels are expected to remain relatively constant and would continue to be in compliance with federal and State standards.

Alternative 1

Less than Significant Impact: Construction of the project would involve a variety of ground disturbing activities, including site preparation, excavation, and grading. Use of heavy equipment and earthmoving operations conducted as part of these activities would generate internal combustion engine emissions and fugitive dust; potential air pollutants associated with these emissions include hydrocarbons; carbon monoxide; nitrogen; carbon; sulfur dioxide; and PM_{10} and $PM_{2.5}$. In general, these emissions would be temporary and localized in nature. In comparison to overall emissions in the region, the contribution by the project is relatively small; this contribution would only negligibly affect regional air quality and would not be expected to affect attainment of the federal or state ambient air quality standards. Furthermore, construction would be conducted in compliance with HAR Title 11 Chapter 60.1 (Air Pollution Control), which specifies that the best practical operation or treatment be implemented such that there is no discharge of visible fugitive dust beyond the property lot line.

Over the long-term operation and maintenance of the project, air emissions would occur from the use of vehicles for operations, maintenance activities, and operation of pump station(s) if needed as a mitigation measure for induced flooding. Other than emissions from maintenance equipment, vehicles, and potentially diesel engine(s) used to power the hydraulic pumps if electrical power is lost during a storm event, there would be no operational emissions from project features. Therefore, the emission levels from operation and maintenance would be negligible due to the infrequency of these activities occurring. Therefore, the proposed project would have short term minor adverse effects and long-term negligible adverse effects to air quality.

Alternative 2B

Less than Significant Impact: In general, the type of project features included in Alternative 2B would have similar construction, operation, maintenance, and mitigation requirements as Alternative 1, such that the nature and degree of impacts are generally expected to be similar. Therefore, refer to the analysis under Alternative 1 for Alternative 2B project impacts. Overall, short-term minor adverse effects and long-term negligible adverse effects would occur to air quality with Alternative 2B.

Alternative 5.3

Less than Significant Impact: In general, the type of project features included in Alternative 5.3 would have similar construction, operation, maintenance, and mitigation requirements as Alternative 1 and Alternative 2B, such that the nature and degree of impacts are generally expected to be similar. Therefore, refer to the analysis under Alternative 1 and Alternative 2B for Alternative 5.3 project impacts. Overall, short-term minor adverse effects and long-term negligible adverse effects would occur to air quality with Alternative 5.3

Alternative 6

Less than Significant Impact: Short-term air quality impacts resulting from implementation of Alternative 6 would occur from the use of construction equipment necessary to elevate or demolish existing structures, as determined necessary. Impacts to air quality resulting from construction equipment emissions would be short-term minor adverse effects. There would be no long-term direct or indirect adverse effects on air quality.

Environmental Commitments

No additional environmental commitments other than the BMPs discussed below would be implemented to minimize impacts to air quality.

Best Management Practices

The following BMPs would be implemented during construction of the project:

Basic Construction Emission Control Practices

- Cover or maintain at least two feet of free board space on haul trucks transporting soil, rock, or other loose material on the site. Any haul trucks that would be traveling along freeways or major roadways should be covered.
- Limit vehicle speeds on unpaved roads to 15 miles per hour (mph).
- Minimize idling either by shutting equipment off when not in use or reducing the time of idling to five minutes. Provide clear signage that posts this requirement for workers at the entrance to the construction site. Construction site includes the construction area, easements, access roads, and rights of way where construction occurs during the implementation of one or more measures.

- Maintain all construction equipment in proper working condition according to manufacturer's specifications. The equipment must be checked by a certified mechanic and determined to be running in proper condition before it is operated.

Fugitive Dust Control Practices

- Limit vehicle speeds on unpaved roads to 15 mph.
- Install one or more of the following track-out prevention measures:
    - A gravel pad to clean the tires of existing vehicles,
    - A tire shaker;
    - A wheel wash system;
    - Pavement extending at least 50-ft from the intersection with the paved public road, or
    - Any other measure(s) as effective as the measures listed above.
- Suspend any excavation operations when wind speeds are high enough to result in emissions across the property line, despite application of other dust control practices.

Additional Air Quality BMPs

- Model year 2010 (MY2010) or newer haul trucks would typically be used for the duration of the project. Use of these trucks would provide the best available emissions controls for nOx and PM emissions. There would potentially be occasions when availability of MY2010 or newer haul trucks is limited, thereby forcing the need to use older trucks to meet construction schedule goals. Should a situation like this arise, the construction contractor would first be required to demonstrate that MY2010 or newer trucks are not available in the general project region before the use of older trucks is authorized by USACE.
- All off-road diesel-powered construction equipment greater than 50 hp would meet Tier-4-off-road emission standards (reference 40 CFR 1039), where available. If a certain tier engine is not available for any off-road equipment larger than 50 hp, that equipment would be equipped with the next lower tier engine (e.g., if Tier 3 is not available use Tier 2), or an engine that is equipped with retrofit controls to reduce exhaust emissions of nOx and diesel PM to no more than the next available tier, unless certified by engine manufacturers that the use of such devices is not practical for specific engine types. If the construction contractor proposed to use off-road diesel-powered construction equipment greater than 50 hp that does not meet Tier 4 off-road emissions standards, such usage would first have to be approved by USACE.
- Construction equipment would incorporate emissions-reducing technology such as specific fuel economy standards.

3.3.4 Groundwater Resources

Regulatory Setting

Relevant federal and state laws/regulations include:

- HRS Chapter 174C (State Water Code)

Existing Conditions

Groundwater generally occurs within basal unconfined flank aquifers within the study area. The basal aquifers located within the Ala Wai watershed are the Nuuanu, Palolo, and Waialae-West aquifer systems, which are part of the Honolulu aquifer sector. It is expected that, where present, high-level dike-impounded and perched groundwater in the upper portions of the watershed contribute to the recharge of the underlying basal aquifers. The State of Hawaii Commission on Water Resource Management (CWRM) is responsible for determining the sustainable yield for each aquifer; the total estimated sustainable yield for the island of Oahu is

407 million gallons per day (mgd) (CWRM, 2008a). The estimated sustainable yield for the Honolulu aquifer sector is 50 mgd. Of this total, the Nuuanu, Palolo, and Waialae-West aquifer systems have estimated yields of 5, 14, and 4 mgd, respectively (CWRM, 2008b). Because of concerns for diminishing reserves of developable groundwater and threats to water quality at developed sources, protection of the Honolulu aquifer sector as a groundwater management area was instituted in 1981, resulting in a requirement for water use permits (CWRM, 1990).

Significance Criteria

Effects on groundwater resources would be considered significant if implementation of an alternative plan would result in any of the following:

- Substantially increase contaminant levels in groundwater.
- Substantially deplete groundwater supplies.
- Interfere substantially with groundwater recharge.

Environmental Consequences

No Action

No Impact: Under the No Action Alternative, none of the flood risk management measures would be implemented. The potential future without project condition assumptions are the same as those discussed in the 2017 Ala Wai Canal Study (USACE, 2017); therefore, that discussion is incorporated by reference.

Alternative 1

Less than Significant Impact: Construction of the project does not require the substantial conversion of pervious surfaces to impervious. The floodwalls constructed of steel sheetpile, concrete, and micro-piles as well as drainage structures would result in the conversion of approximately 2.44 acres of pervious surface area to impervious (Table 11). Conversely, the construction of detention basins and earthen levees would retain pervious surfaces that would continue to be permeable. During construction, storage and use of some hazardous materials would occur. If handled inappropriately, these materials could accidentally spill or inadvertently discharge to groundwater. Construction activities would involve the use of heavy equipment, cranes, compactors, and other construction equipment that use petroleum products such as fuels, lubricants, hydraulic fluids, and coolants, all of which are detrimental to groundwater quality. BMPs listed below would be implemented to minimize the risk of inadvertent spills. Construction activities may also require the use of water trucks to minimize potential fugitive dust during construction. The amount of water required during construction, though, would not substantially decrease groundwater supplies.

Table 11: The Area of Impervious Surface Created by Alternative 1 Project Features.

Feature	Length (ft)	Width (ft)	Area (ft^2)	Area (acres)	Impervious Surface (acres)

Road Closure Structure 1	180	6	1,080	0.025	0.025
Road Closure Structure 2	90	6	540	0.012	0.012
Ala Wai Golf Course Berm	10,665	48	511,920	3.917	N/A
Drainage Structure 1	147	33	4,851	0.111	0.111
Drainage Structure 2	50	4	200	0.005	0.005
Drainage Structure 3	50	4	200	0.005	0.005
Drainage Structure 4	50	4	200	0.005	0.005
Drainage Structure 5	50	4	200	0.005	0.005
Road Closure Structure 1	40	6	240	0.006	0.006
Road Closure Structure 2	80	6	480	0.011	0.011
				TOTAL	**2.44**
N/A = Not Applicable – would not convert pervious surface to impervious					

Long-term, the operation and maintenance of the project is not expected to result in any additional conversion of pervious surfaces to impervious; therefore, O&M would not interfere substantially with groundwater recharge. Similar to construction, heavy equipment may be needed during future maintenance activities for repairs or debris removal. Equipment used would need petroleum products which are detrimental to groundwater quality. BMPs listed below would be implemented during maintenance activities to minimize the risk of inadvertent spills. No heavy equipment is needed for operation of project features. O&M activities do not require the use of water; therefore, the project would not decrease groundwater supplies long-term. Alternative 1 also includes a broad range of mitigation measures that may be needed to minimize induced flooding. None of the proposed mitigation measures would involve extraction or withdrawals of groundwater. Dewatering may be required during construction of pump station(s) if found to be necessary to minimize induced flooding, however, any adverse effect to groundwater would be short-term and negligible. Overall, with the implementation of BMPs, the

project is expected to have a short-term less than significant adverse effect and a long-term negligible adverse effect on groundwater supplies, contaminant levels, or recharge.

Alternative 2B

Less than Significant Impact: In general, the type of project features included in Alternative 2B would have similar construction, operation, maintenance, and mitigation requirements as Alternative 1, such that the nature and degree of potential impacts to groundwater are generally expected to be similar. The primary difference between the alternatives is some of the project features and therefore the amount of impervious area created. Alternative 2B would convert approximately 8.67 acres of pervious surface to impervious surface (Table 12). Even though the amount of impervious surface created is greater in Alternative 2B than Alternative, the nature and degree of potential impacts to groundwater are generally expected to still be similar. Therefore, refer to the analysis under Alternative 1 for Alternative 2B project impacts. Overall, with the implementation of BMPs, the project is expected to have a short-term less than significant adverse effect and a long-term negligible adverse effect on groundwater supplies, contaminant levels, or recharge.

Table 12: The Area of Impervious Surface Created by Alternative 2B Project Features.

Feature	Length (ft)	Width (ft)	Area (ft^2)	Area (acres)	Impervious Surface (acres)

				TOTAL	**8.67**
N/A = Not Applicable – would not convert pervious surface to impervious					

Alternative 5.3

Less than Significant Impact: In general, the type of project features included in Alternative 5.3 would have similar construction, operation, maintenance, and mitigation requirements as Alternative 1 and Alternative 2B, such that the nature and degree of potential impacts to groundwater are generally expected to be similar. The primary difference between the alternatives is some of the project features and therefore the amount of impervious area created. Alternative 5.3 would convert approximately 8.03 acres of pervious surface to impervious surface (Table 13). Therefore, the amount of pervious surface being created under Alternative 5.3 is less than Alternative 2B but greater than Alternative 1. Even though the amount of pervious surface is different than Alternative 1 or 2B, the nature and degree of potential impacts to groundwater are generally expected to still be similar. Therefore, refer to the analysis under Alternative 1 and Alternative 2B for project impacts. Overall, with the implementation of BMPs, the project is expected to have a short-term less than significant adverse effect and a long-term negligible adverse effect on groundwater supplies, contaminant levels, or recharge.

Table 13: The Area of Impervious Surface Created by Alternative 5 Project Features.

Feature	Length (ft)	Width (ft)	Area (ft^2)	Area (acres)	Impervious Surface (acres)

				TOTAL	**8.03**
N/A = Not Applicable – would not convert pervious surface to impervious					

Alternative 6

No Impact: No short-term direct or indirect groundwater impacts would occur because of implementation of Alternative 6 because land disturbance for this alternative would be limited to modification of existing buildings. Implementation of alternative 6 would require construction access to all structures to be treated; this would be expected to be from existing roads. Similarly, localized maintenance such as repairs will be needed over time. Overall, no direct or indirect long-term adverse effects to groundwater would occur because of this alternative. Appropriate erosion and sediment control measures would be utilized during construction.

Environmental Commitments

No additional environmental commitments other than the BMPs discussed below would be implemented to minimize impacts to groundwater.

Best Management Practices

Implementation of the following BMPs would help ensure that effects on groundwater quality would remain at less than significant levels. Standard BMPs include:

- A fuel spill management plan would be developed for the project by the construction contractor and would be implemented by the contractor.
- Construction equipment and vehicles would be fueled and maintained in specific staging areas only, which would be designed to capture potential spills.
- Fuels and hazardous materials would not be stored on site. Any spills of hazardous material would be cleaned up immediately by the construction contractor.
- Construction vehicles and equipment would be inspected frequently and appropriately maintained by the construction contractor to help prevent dripping of oil, lubricants, or any other fluids.

3.3.5 Surface Water Resources

Regulatory Setting

Relevant federal and state laws/regulations include:

- Clean Water Act, Section 401, and Section 404
- Rivers and Harbors Act, Section 10
- HRS Chapter 174C (State Water Code)

Existing Conditions

The Ala Wai watershed is in urban Honolulu and has a drainage area of approximately 19 square miles. Communities within the drainage area include Manoa, Palolo, Makiki, McCully, Moiliili, and Waikiki. The watershed consists of three main tributaries, the Manoa, Palolo, and Makiki streams.

Makiki Stream is a relatively small stream originating near 1,850 feet on the southwestern flank of Mt. Tantalus in the Koolau Mountains and flows southwestwards for approximately 3.5 miles

to its terminus in the Ala Wai Canal. The stream has three major branches, these being from west to east the Kanaha, Kanealole, and Moleka streams, the latter two of which join prior to their confluence with the Kanaha. The upper half of the Makiki catchment lies in steep, forested terrain on the slopes of Mt. Tantalus and Round Top, an area that receives up to 134 inches of rain annually (Giambelluca et al., 2013). The stream in this section flows in natural, unmodified channels, heavily shaded by a forest, and is fed by two major springs, the Makiki Spring on the Kanealole branch, and the Herring Spring on the Moleka branch. At approximately 150 feet elevation, just downstream from Makiki Street, the stream channel is artificially confined within a concrete box culvert, which runs under the streets and neighborhoods of Honolulu before re-emerging at sea level near the intersection of Philip Street and Kalakaua Avenue. From this point the stream runs in an open concrete channel for another 0.4 miles to the Ala Wai Canal. There are no historic or active ditch diversions in the Makiki Stream catchment.

Manoa Stream is a large stream in a bowl-like catchment, originating near 2,800 feet on the southwestern flank of Konahuanui peak and adjacent ridgelines in the Koolau Mountains, and flows southwestwards for approximately 5.75 miles to its terminus in the Ala Wai Canal. The stream has two major branches, these being the Waihi on the west side of the basin, and the Waiakeakua on the east. The upper half of the Manoa catchment lies in steep, forested terrain on the slopes of the Koolau Mountains, in a very wet area that receives up to 151 inches of rain annually at the headwaters of the Waiakeakua branch (Giambelluca et al., 2013). The stream in its upper reaches flows in natural unmodified channels for approximately 2.25 miles, being heavily shaded by forest. Below Paradise Park, the stream passes through suburban neighborhoods in a partially modified channel for about 1.0 mile. At the Mano District Park, near 150 feet elevation the stream becomes confined within an artificial concrete channel, which continues downstream to the East Manoa Road bridge. Downstream from this bridge the stream flows in a re-aligned but partially natural channel mostly following the base of the steep eastern wall of Manoa Valley. Downstream from Kanewai Park, at approximately 30 feet elevation, the stream channel has been straightened, but not concrete-lined, and continues in this fashion for 1.4 miles, passing below the H-1 Freeway and then continuing to its confluence with the Ala Wai Canal.

Palolo Stream is another large stream in a somewhat more tightly confined catchment than adjacent Manoa Stream and originates near 2,665 feet on the southwestern flank of Mt. Olympus and adjacent ridgelines in the Koolau Mountains and flows southwestwards for approximately 4.4 miles before joining with Manoa Stream just upslope of the H-1 Freeway. The stream has two major branches, these being the Pukele on the west side of the basin, and the Waiomao on the east. The upper third of the Palolo catchment lies in steep, forested terrain on the slopes of the Koolau Mountains, in a wet area that receives up to 120 inches of rain annually at the headwaters of the Pukele branch, and 104 inches annually at the headwaters of the Waiomao branch (Giambelluca et al., 2013). The stream headwaters in these upper reaches traverse unmodified channels for approximately 2.0 miles, being shaded by a forest. At approximately 530 feet elevation both stream branches begin to traverse the suburban neighborhoods of Palolo Valley, with their channels becoming progressively more straightened and modified. Pukele Stream appears to be intermittent in its upper reaches but receives significant spring inflow just upstream of the 10th Avenue Bridge. Not far downstream of this bridge, at 250 feet elevation, the stream becomes confined within a concrete channel, and retains this artificial character for the remaining 0.30 mile of its length, until its confluence with Waiomao Stream at 225 feet elevation. The Waiomao Stream exhibits higher volume in its headwaters, receiving perennial inflow from the outlet of a perched wetland in Kaau Crater. This branch also retains a more natural character to its channel until just before its confluence with the Pukele Stream, at which point it is confined within an artificial concrete channel, which then

continues for the remaining 2.0 miles length of the stream until its confluence with Manoa Stream just downslope of Kanewai Park.

The Ala Wai Canal was man-made in the 1920s and is about 2 miles long, originally built to drain the wetlands and formed Waikiki. The width of the Canal ranges between 150 and 250 feet. The original depths of the Ala Wai Canal were approximately 10 to 20 feet below mean sea level (msl) behind Waikiki, 10 to 13 feet below msl between the confluence with Makiki Stream and Ala Moana Boulevard Bridge, and 25 feet below msl beyond the Ala Moana Boulevard Bridge (Noda, 1992). However, sedimentation has decreased the depths over time. Portions of the Ala Wai Canal have been dredged a total of four times: in 1967, 1978-1979, 2002-2003, and 2019-2021. The Canal intercepts flows from Manoa and Palolo stream (via the Manoa-Palolo Drainage Canal) and Makiki Stream (as well as numerous storm drain outfalls), and empties into the Ala Wai Boat Harbor. The boat harbor connects to Mamala Bay via a channel that was dredged through the reef platform when the harbor was built in 1935. Mamala Bay encompasses the ocean area offshore of southern Oahu from Diamond Head Crater to Barbers Point (Kalaeola) Deep Draft Harbor.

The upper reaches of the basin area very steep and rock and incised into the Koolau Volcano, between 40-feet and 2,400 feet elevation. The Makiki and Manoa basins typically receive more than 160 inches of rain annually, while Palolo valley receives less. The lower portion of the basin is much less steep and is urbanized. Significant portions of the lower watershed are hardened, impervious surfaces with sewer system drainage actively directing most of the runoff in less intense events. The Ala Wai Canal and Waikiki basin receive about 30 inches of precipitation, annually. High-intensity rainfall events in the mountains usually produce flashy flood events in the small drainage basin. Time to peak is usually one hour and even for large intense storms, the rise and recessions of the flood hydrography usually occurs within 6 hours (USACE, 2020).

The U.S. Fish and Wildlife Service's (USFWS) National Wetlands Inventory (NWI) Database was used to query wetlands that have been identified within the study area (Figure 6 and Figure 7). It is important to note that the NWI Database provides only reconnaissance level information on the location, type, and size of wetland resources. Certain wetland habitats are excluded from the NWI because of limitations of aerial imagery as the primary data source used to detect wetlands. Wetland habitats that are excluded from the NWI include seagrasses or submerged aquatic vegetation that are found in the intertidal and subtidal zones of estuaries and nearshore coastal waters. Some deepwater reef communities (e.g., coral or tuberficid worm reefs) have also been excluded from the database.

Manoa Stream is shown as having 24.07 acres of freshwater forested/shrub wetland (USFWS, 2022). The 24.07 acres of freshwater forested/shrub wetland include the headwater tributaries of Manoa and the Manoa mainstem down to its confluence with Palolo Stream. Additionally, riverine habitat is found within approximately 0.83 acres of Waihi Stream, 0.15 acres of Aihualama Stream, 0.56 acres of Waaloa Stream, and 1.2 acres of Mano Stream. The NWI Database also shows a single freshwater emergent wetland of approximately 0.19 acres located near Waihi Stream, about 0.15 miles upstream of the confluence of Waihi Stream with Waiakeakua Stream.

Makiki Stream is shown as having 12.28 acres of freshwater forested/shrub wetland, which is primarily located within the headwater tributaries (i.e., Kanealoloe Stream, Moleka Stream, and Kanaha Stream). The mainstem of Makiki Stream is comprised of approximately 4.03 acres of riverine habitat.

Palolo Stream has approximately 16.73 acres of freshwater forested/shrub wetland, which is mainly located within the headwater tributaries (i.e., Waiomao Stream and Pukele Stream). The Pukele Stream tributary also has 0.09 acre of freshwater emergent wetland and 0.78 acre of freshwater pond. The Waiomao tributary also has 20.74 acres of freshwater emergent wetland and an additional 15.66 acres of freshwater forested/shrub wetland. The Palolo Stream mainstem is primarily comprised of 4.75 acres of riverine habitat, extending from the convergence of its tributaries to the confluence of Palolo and Manoa streams.

The NWI Database shows 59.31 acres of the Ala Wai Canal as riverine habitat. The Ala Wai Boat Harbor is comprised of 58.86 acres of estuarine and marine deepwater habitat. Estuarine and marine wetlands extend along the nearshore areas of Aina Moana (Magic Island) Park, Kahanamoku Beach, Fort DeRussy Beach Park, and Waikiki Beach (approximately 8.85 acres).

Other nearby wetlands according to the NWI Database include 3.65 acres of freshwater forested/shrub wetland and 0.97 acres of freshwater pond at the Ala Wai Golf Course. The Kahanamoku Lagoon includes approximately 3.88 acres of estuarine and marine deepwater habitat and 0.73 acres of estuarine and marine wetland. The Aina Moana (Magic Island) Park includes approximately 5.09 acres of estuarine and marine deepwater habitat and 1.25 acres of estuarine and marine wetland (USFWS, 2022).

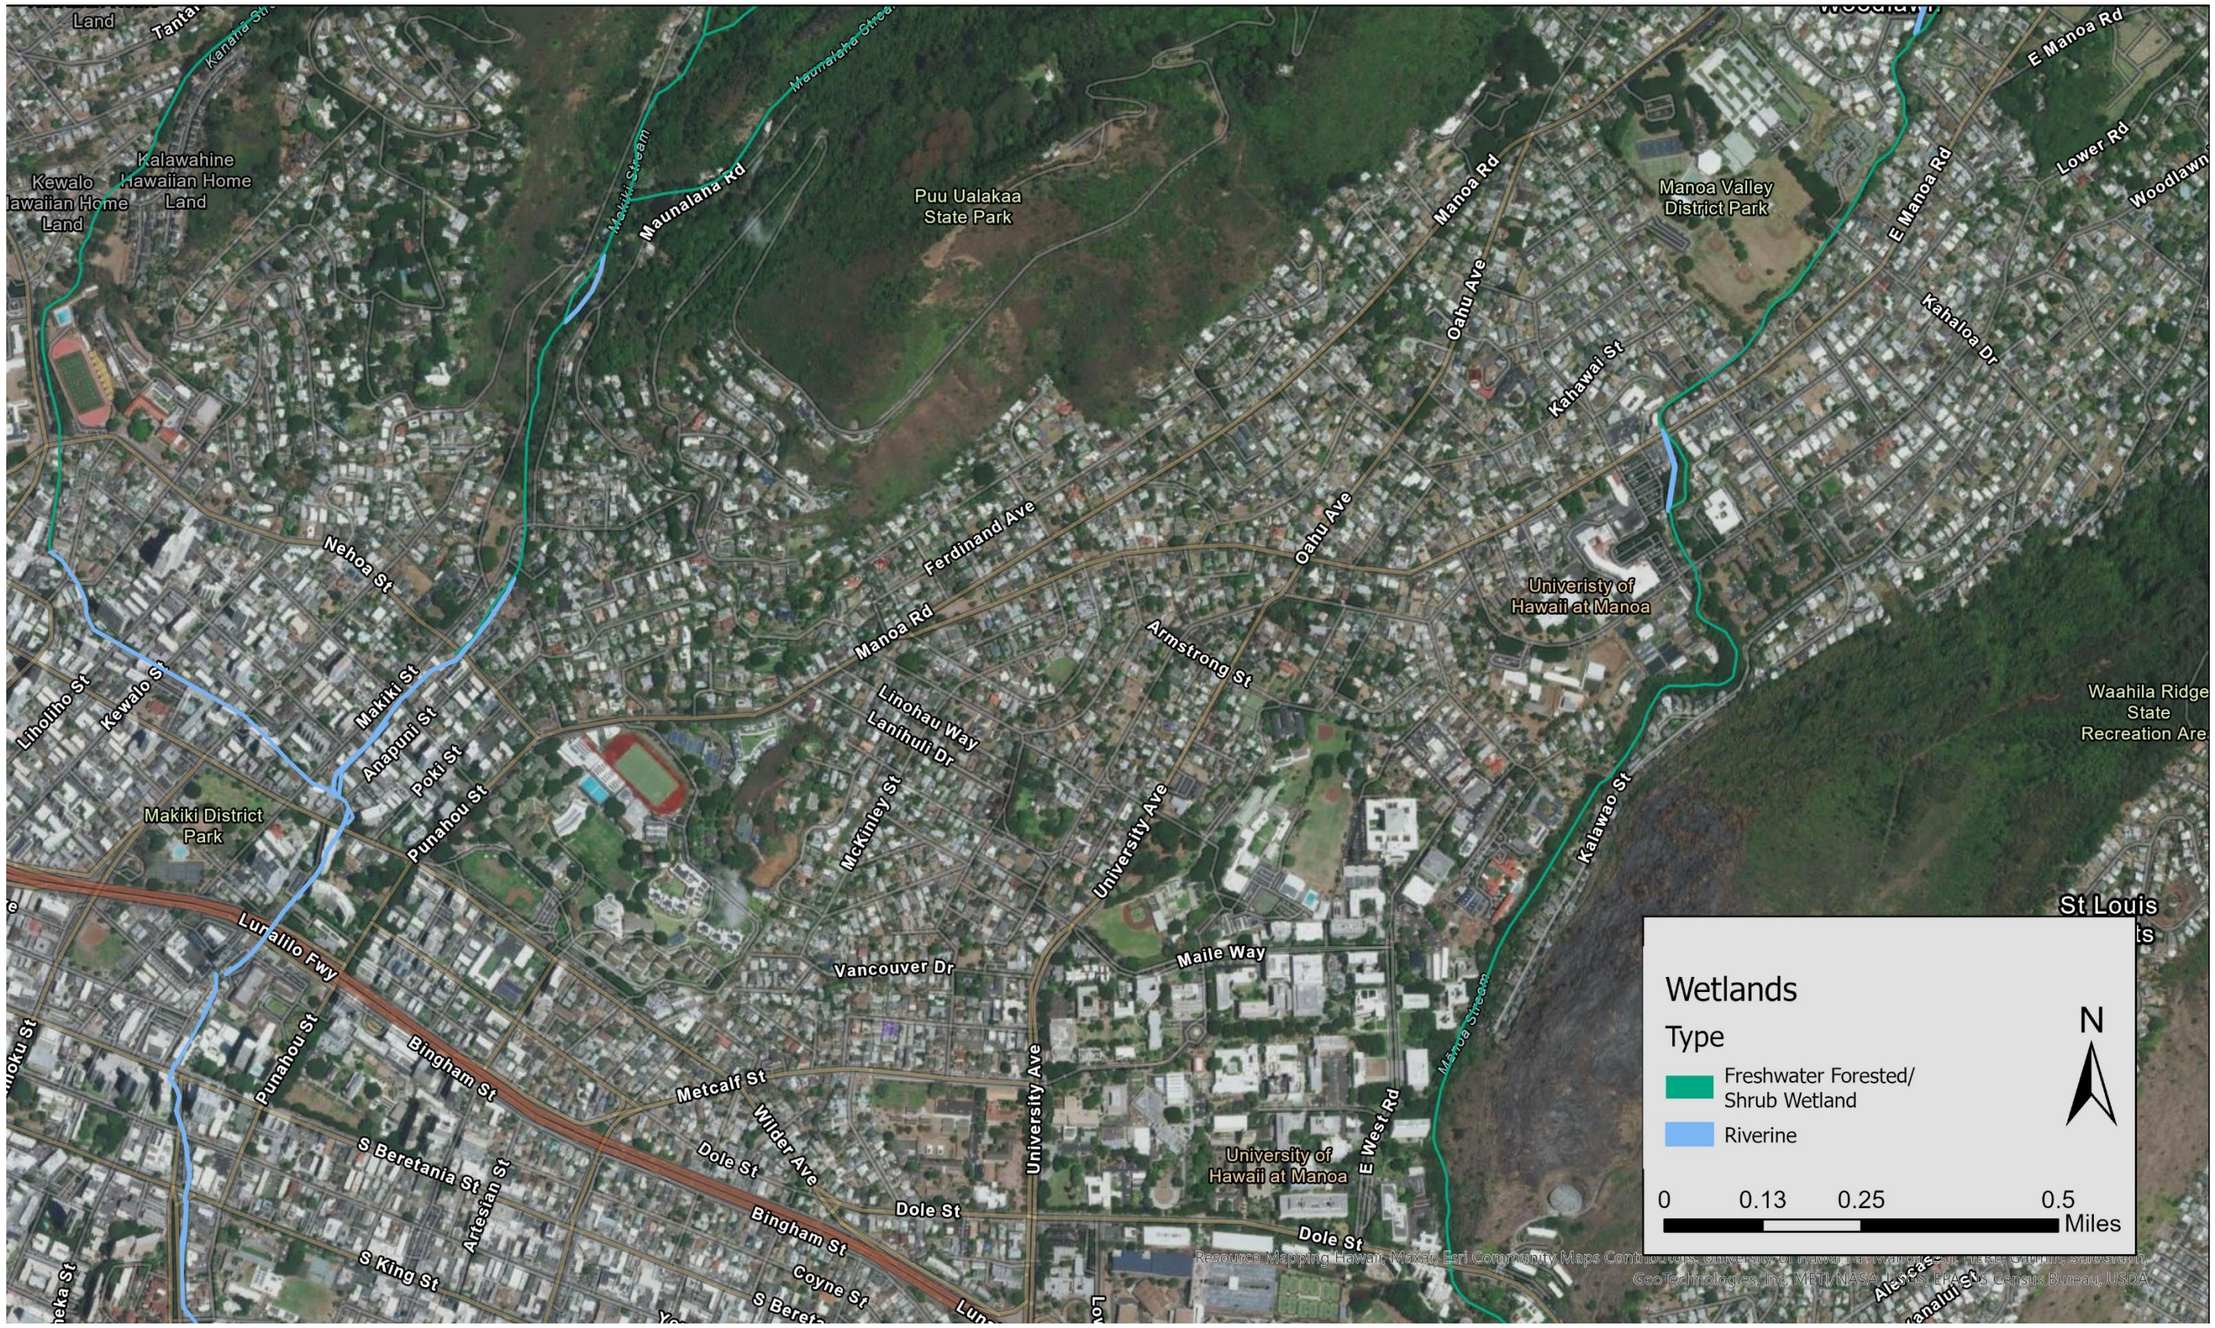

Figure 6: Location of National Wetland Inventory Wetlands Within the Lower Watershed of the Study Area.

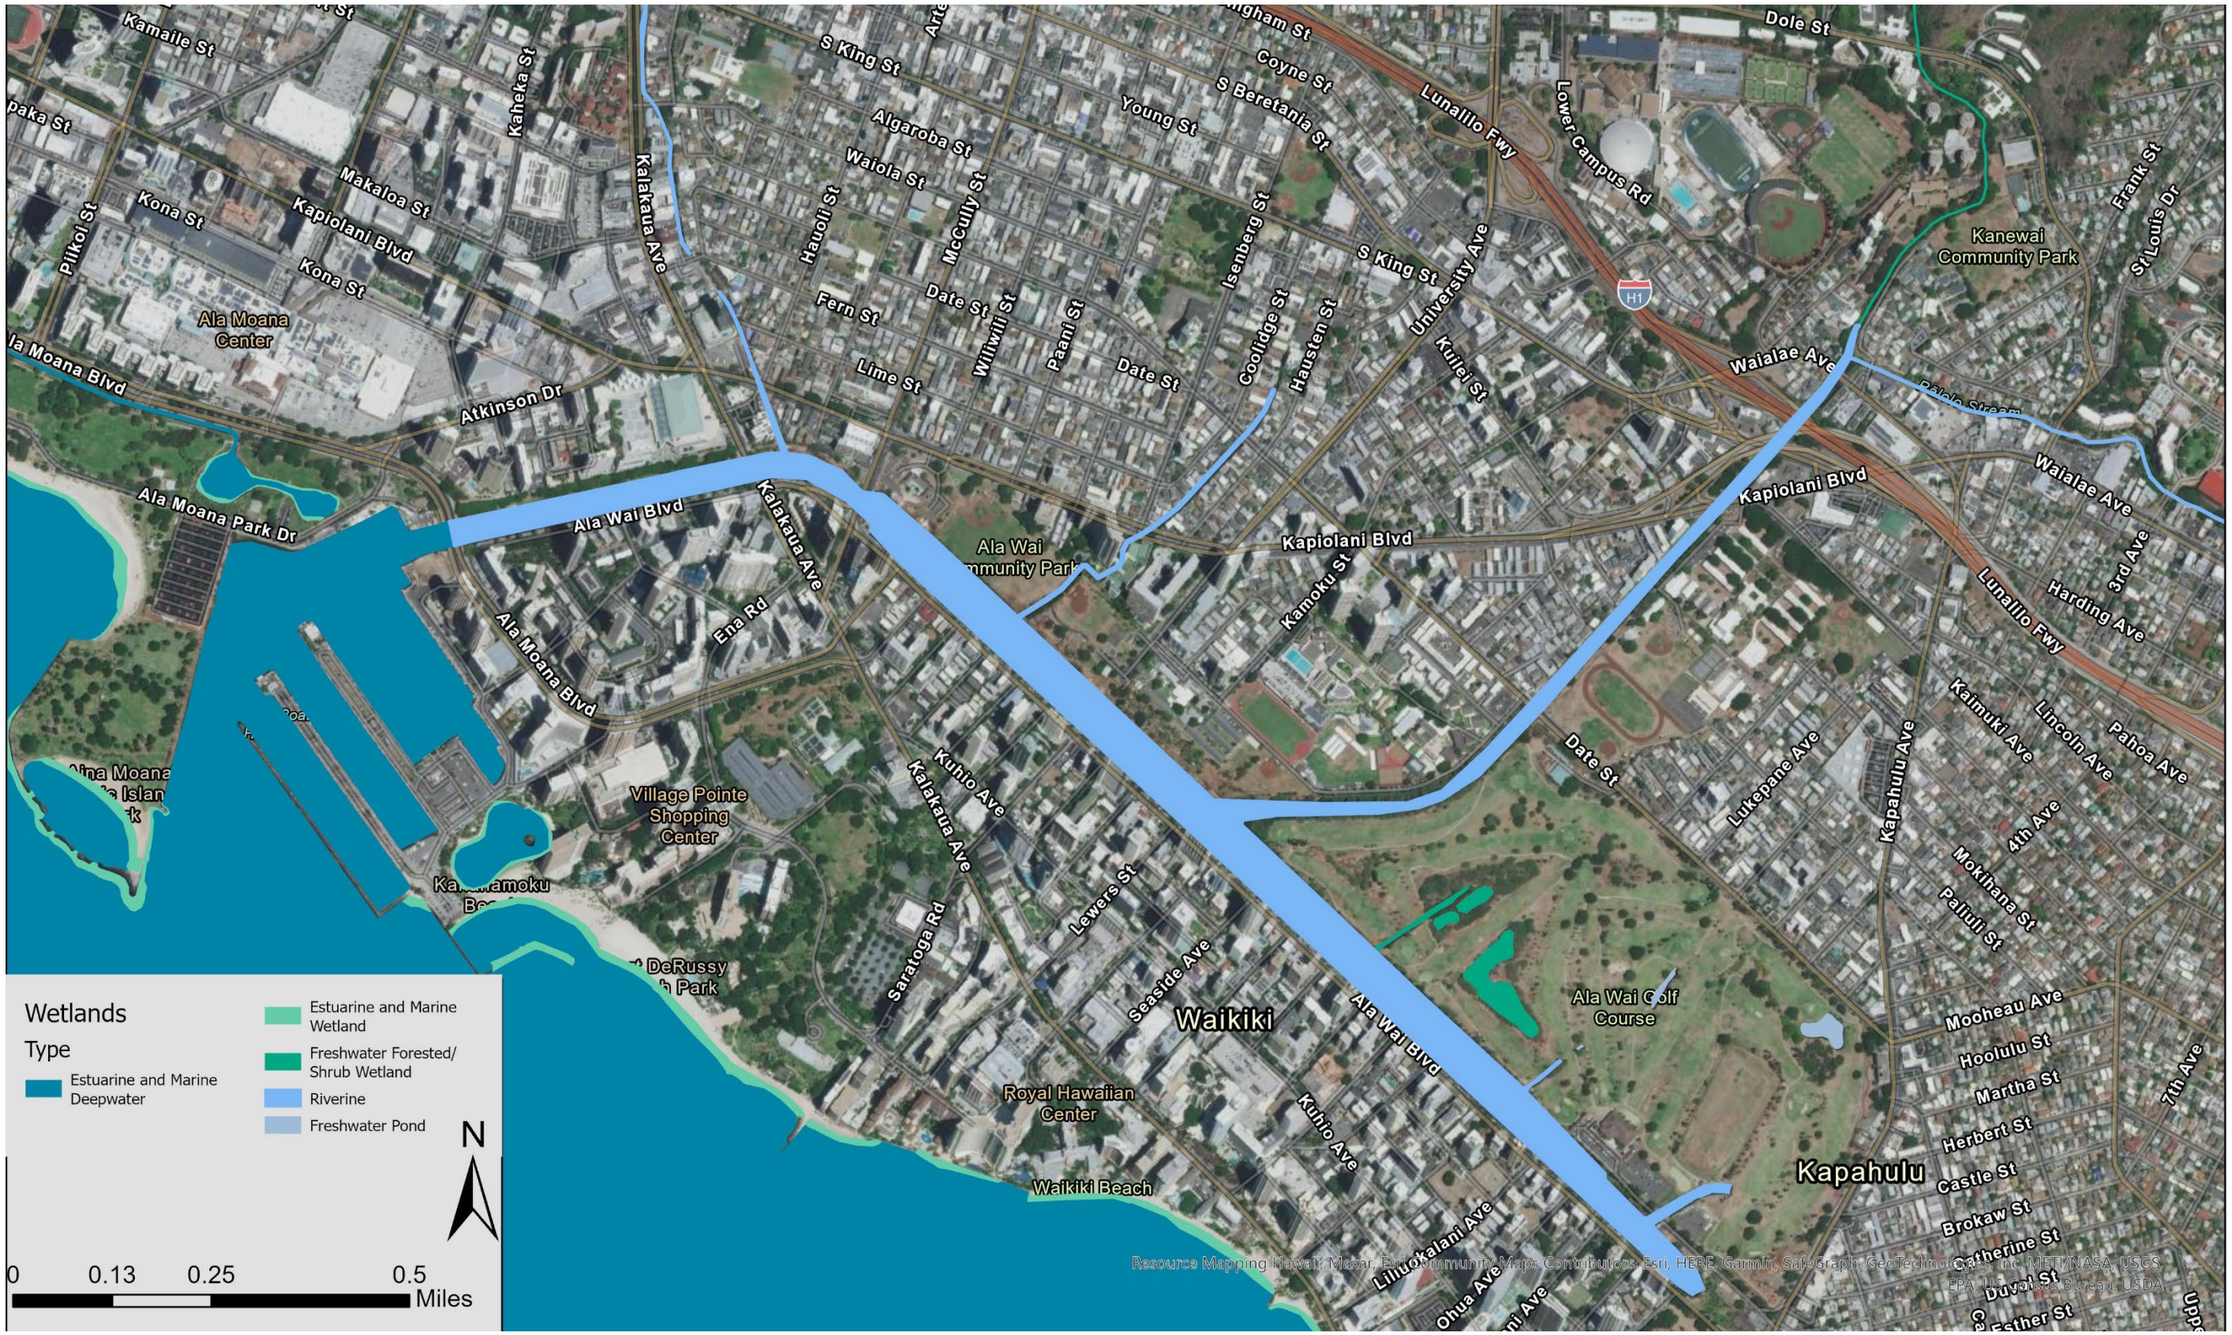

Figure 7: Location of National Wetland Inventory Wetlands Within the Lower Watershed of the Study Area.

Significance Criteria

Effects to surface water resources would be considered significant if the proposed project would result in any of the following:

- Obstruct or otherwise change the course of a stream or canal.
- Remove, fill, or substantially disturb a jurisdictional wetland or other Waters of the U.S.
- Substantially modify or otherwise adversely affect a floodplain.
- Significantly increase channel and/or bank erosion or reduce channel stability.
- Substantially affect sediment transport dynamics.

Environmental Consequences

No Action

No Impact: Under the No Action Alternative, none of the flood risk management measures would be implemented, such that no modifications to surface water features would occur. The potential future without project condition assumptions are the same as those discussed in the 2017 Ala Wai Canal Study (USACE, 2017); therefore, that discussion is incorporated by reference.

Alternative 1

Less than Significant Impact: Construction of Alternative 1 includes the Woodlawn Drive Floodwall, Koali Road Floodwall, Kaimuki High School Floodwall, and road closure structures which would not involve work within a stream or canal. The Makiki District Park Detention Basin (including the Kanaha Floodwall), Manoa Valley Park, and Ala Wai Golf Course detention basins are not instream detention basins like those analyzed in the 2017 Ala Wai Study (USACE, 2017). Instead, the detention basins are built on land adjacent to the streams within the Ala Wai watershed; therefore, the berms/floodwalls associated with these features would not involve work within a stream or canal. However, the construction of inlet and outlet structures for the detention basins would involve work within a stream or canal. None of these measures would permanently obstruct or change the course of a waterway, or substantially modify the existing floodplain. However, they would involve the placement of fill material within the channels, which are Waters of the U.S. Specifically, the construction of drainage structures for the detention basins would require the placement of materials including compacted fill and concrete. It is important to note that a formal jurisdictional determination of Waters of the U.S. have not yet been completed for the proposed project action area; however, all the streams and canals in the watershed are assumed to be Waters of the U.S. (AECOS, 2014). Jurisdictional wetlands are not expected to be present outside the defined channel limits. This information will be verified during the next phase of the project through a formal jurisdictional determination in accordance with the new Clean Water Rule: Definition of “Waters of the United States” (33 C.F.R. Part 328). The only wetland habitat, according to the NWI Database (Figure 7), that would be impacted by the project is located on the Ala Wai Golf Course. Approximately 0.005 acre of freshwater forested/shrub wetland would be permanently filled with a concrete weir that would act as one of the outlet drainage structures for the Ala Wai Golf Course detention basin.

Construction of the Makiki Park District and Manoa Valley Park District detention basins would also involve excavation to provide adequate detention capacity, but this excavation activity would not involve work within a stream or canal. Long-term, the inlet and outlet drainage structures would require periodic removal of debris and potentially sediment. The detention basins would also require periodic debris removal but this maintenance activity for the detention basins would not involve work within a stream or canal. All debris removed from the inlet and outlet structures and detention basins would be disposed of in an approved offsite location. The

estimated volume of fill material that would be placed within Waters of the U.S. is summarized in Table 14.

In addition to the above, implementation of Alternative 1 would likely include mitigation measures to minimize induced flooding within the watershed. Mitigation measures currently under consideration include nonstructural measures such as dry/wet floodproofing, elevation, and buy outs. For an analysis of nonstructural measures refer to Alternative 6 below. A structural mitigation measure under consideration is a pump station(s). If a pump station is found to be necessary additional design and analysis would occur. In general, the pump station would be constructed upland and adjacent to the stream, but not within the stream. Therefore, construction of the pump station if necessary is not expected have any short-term adverse effects to surface water by obstructing or otherwise changing the course of a stream; remove, fill or substantially disturb a jurisdictional wetland or other Waters of the U.S.; adversely affect a floodplain; increase channel and/or bank erosion or reduce channel stability; or substantially affect sediment transport dynamics.

Table 14: Estimated Excavation and Discharge of Fill Within Waters of the U.S. for Alternative 1.

Measure	Length of Stream to be Disturbed (linear feet)	Length of Stream in Permanent Footprint (linear feet)	Construction Excavation (yd^3)	Construction Fill (yd^3)	O&M Excavation (yd^3)	O&M Fill (yd^3)

Ala Wai Golf Course Detention Basin Drainage Structure 5	505	505	1179	571	0	0
TOTAL	**550**	**627**	**1,937**	**1,215**	**0**	**0**

Long-term operation and maintenance of Alternative 1 is not anticipated to increase channel and/or bank erosion. Overall, the detention basins are designed to reduce peak flows, which in turn could reduce erosion rates and provide some degree of benefit to channel stability. As discussed above, debris that accumulative within the inlet/outlet structures and the detention basins would be removed as part of routine O&M activities and disposed of at an approved, offsite location. However, this is expected to occur on an infrequent basis. The minimal discharge of fill material for the inlet/outlet structures is expected to result in a less than significant impact. Similarly, the operation and maintenance of a pump station, if found to be necessary, is not expected to have a long-term adverse effect to surface water. The pump station would only be trigged to begin operating in the event of a storm event; therefore, much of the time the pump station would not be in operation. BMPs listed below would be implemented during construction to ensure potential impacts remain less than significant to surface waters.

Alternative 2B

Less than Significant Impact: In general, the type of project features included in Alternative 2B would have similar construction, operation, maintenance, and mitigation requirements as Alternative 1, such that the nature and degree of potential impacts to surface water resources are generally expected to be similar. It is important to note that Alternative 2B also includes a floodwall around the Ala Wai Canal which would require interior drainage structures. It is important to note that a formal jurisdictional determination of Waters of the U.S. have not yet been completed for the proposed project action area; however, all the streams and canals in the watershed are assumed to be Waters of the U.S. (AECOS, 2014). Jurisdictional wetlands are not expected to be present outside the defined channel limits. This information will be verified during the next phase of the project through a formal jurisdictional determination in accordance with the new Clean Water Rule: Definition of “Waters of the United States” (33 C.F.R. Part 328). Refer to Table 15 for the estimated volume of fill that would be placed into Waters of the U.S.

Table 15: Estimated Excavation and Discharge of Fill Within Waters of the U.S. for Alternative 2B.

Measure	Length of Stream to be Disturbed (feet)	Length of Stream in Permanent Footprint (feet)	Construction Excavation (yd^3)	Construction Fill (yd^3)	O&M Excavation (yd^3)	O&M Fill (yd^3)
Makiki District Park Detention Basin Levee	0	0	0	0	0	0

Measure	Length of Stream to be Disturbed (feet)	Length of Stream in Permanent Footprint (feet)	Construction Excavation (yd^3)	Construction Fill (yd^3)	O&M Excavation (yd^3)	O&M Fill (yd^3)
Ala Wai Canal Floodwall Drainage Structure 4	50	9	3	2	0	0
Ala Wai Canal Floodwall Drainage Structure 5	50	8	2	1	0	0
Ala Wai Canal Floodwall Drainage Structure 6	50	10	4	3	0	0
TOTAL	**500**	**89**	**119**	**65**	**0**	**0**

Although Alternative 2B has additional features that are not included in Alternative 1 (e.g., Ala Wai Canal Floodwall), Alternative 2B also doesn't include all the features that Alternative 1 has (e.g., Manoa Valley District Park Detention Basin). Overall, Alternative 2B would disturb slightly less linear feet of stream than Alternative 1, but construction fill placed into waters of the U.S., primarily due to backfilling around the inlet/outlet/drainage structures, would be less than that required for Alternative 1. Alternative 2B would require approximately 65 cy^3 of fill into waters of the U.S. whereas Alternative60omplld require approximately 1,215 cy^3 of fill into waters of the U.S. Although Alternative 2B would require less fill into waters of the U.S., the general impacts to surface water resources during construction and post construction would be similar. Therefore, refer to the analysis under Alternative 1 for Alternative 2B project impacts.

Alternative 5.3

Less than Significant Impact: In general, the type of project features included in Alternative 5.3 would have similar construction, operation, maintenance, and mitigation requirements as Alternative 1 and Alternative 2B, such that the nature and degree of potential impacts to surface water resources are generally expected to be similar. It is important to note that Alternative 5.3 also includes a floodwall around the Ala Wai Canal. Since the floodwall is slightly different in length when compared to Alternative 2B, additional drainage structures are required for interior drainage. It is important to note that a formal jurisdictional determination of Waters of the U.S. have not yet been completed for the proposed project action area; however, all the streams and canals in the watershed are assumed to be Waters of the U.S. (AECOS, 2014). Jurisdictional wetlands are not expected to be present outside the defined channel limits. This information will be verified during the next phase of the project through a formal jurisdictional determination in accordance with the new Clean Water Rule: Definition of "Waters of the United States" (33 C.F.R. Part 328). The only wetland habitat, according to the NWI Database (Figure 7), that would be impacted by the project is located on the Ala Wai Golf Course. Approximately 0.005 acre of freshwater forested/shrub wetland would be permanently filled with a concrete weir that would act as one of the outlet drainage structures for the Ala Wai Golf Course detention basin. Refer to Table 16 for the estimated volume of fill that would be placed into Waters of the U.S.

Table 16: Estimated Excavation and Discharge of Fill Within Waters of the U.S. for Alternative 5.

Measure	Length of Stream to be Disturbed (feet)	Length of Stream in Permanent Footprint (feet)	Construction Excavation (yd^3)	Construction Fill (yd^3)	O&M Excavation (yd^3)	O&M Fill (yd^3)
Woodlawn Drive Floodwall	0	0	0	0	0	0
Koali Road Floodwall	0	0	0	0	0	0

Measure	Length of Stream to be Disturbed (feet)	Length of Stream in Permanent Footprint (feet)	Construction Excavation (yd^3)	Construction Fill (yd^3)	O&M Excavation (yd^3)	O&M Fill (yd^3)
Ala Wai Canal Floodwall Drainage Structure 13	50	10	6	3	0	0
Ala Wai Canal Floodwall Drainage Structure 14	50	10	6	3	0	0
TOTAL	**1,505**	**720**	**1,510**	**743**	**0**	**0**

Although Alternative 5.3 has fewer measures than both Alternative 1 and Alternative 2B it has the greatest impact to surface water resources in terms of linear feet of stream impacted and fill discharged into waters of the U.S. Although Alternative 5.3 does have a greater impact to surface waters, the impact is still considered less than significant since the linear feet of stream being permanently impacted is minimal. Alternative 5.3 would disturb approximately 1,505 linear feet during construction, but only 720 linear feet of stream would be permanently impacted. In addition, Alternative 5.3 includes the excavation of approximately 1,510 cy^3 of material from channel banks with 743 cy^3 of fill material discharged into waters of the U.S., primarily due to backfilling around drainage structures. No long-term excavation or fill material placement is anticipated to occur. Even though Alternative 5.3 would require more fill into waters of the U.S., the general impacts to surface water resources during construction and post construction would be similar. Therefore, refer to the analysis under Alternative 1 for Alternative 2B project impacts.

Alternative 6

No Impact: No short-term direct or indirect surface water impacts would occur as a result of implementation of Alternative 6 because land disturbance for this alternative would be limited to modification of existing buildings located upland. Implementation of Alternative 6 would require temporary construction access to all structures to be treated which would be expected to occur from existing roads. Similarly, localized maintenance such as repairs will be needed over time. Overall, no long-term direct or indirect adverse effects to surface waters would occur as a result of this alternative. Appropriate erosion and sediment control measures would be utilized during construction.

Environmental Commitments

No specific environmental commitments for surface waters apply.

Best Management Practices

No specific BMPS associated with impacts to surface waters apply. Refer to BMPs for water quality that would also be applicable to surface waters.

3.3.6 Hydrology and Hydraulics

Regulatory Setting

Relevant federal and state laws/regulations include:

- CCH Drainage Standards (2000)

Existing Conditions

The Ala Wai watershed is located on the leeward side of Oahu Island, Hawaii, on the southern slope of the extinct Koolau volcano between Punchbowl Crater and Diamond Head Crater. The watershed is about 19 square miles, bounded to the north by the Koolau Mountains (with ridge crest elevations about 2,400 feet), and by Mamala Bay, to the south. The Ala Wai watershed is comprised of three major drainages that include the Makiki drainage (1,687 acres), Manoa and Palolo drainage (6,247 acres) and storm water drainage from Kapahulu, Moiliili, Ala Moana, and Waikki areas (4,099 acres), all of which drain into the Ala Wai Canal. Makiki Stream, Manoa Stream, and Palolo Stream are considered perennial streams, supporting surface flows in all or part of each stream segment throughout the year. The drainage area encompassing Ala Wai Canal and Waikiki receives about 30 inches of annual rainfall. High-intensity rainfall on steep slopes of the small drainage basin can produce very flashy flood events in the lower basin. Time to peak is usually less than 1 hour and even for large intense storms, the rise and recession of the flood hydrograph usually occurs within 6 hours.

Several heavy rainfall events have occurred that have caused flooding within the study area (NOAA, 2022a):

- November 29 – December 8, 2003: Several rain gauges on Oahu recorded nearly 13 inches of rain, most of which fell in about 6 hours.
- August 2-4, 2004: Hurricane Darby remnants caused thunderstorms that affected the entire island of Oahu and dumped several inches of rain in a few hours. A few streams overflowed their banks and minor landslides occurred. Significant ponding occurred on roads.
- October 30, 2004: Heavy showers and thunderstorms led to significant rainfall amounts (at times over 5 inches per hour). The focus of the heaviest rain occurred over the southern portion of the Koolau Mountains on Oahu, resulting in Manoa Stream overflowing its banks and causing significant flooding in Mano Valley, including the University of Hawaii campus.
- February 19-21, 2006: Heavy rains on Oahu caused urban flooding near the Middle Street ramp on the H-1 freeway and in the low-lying Mapunapuna business district.
- March 1-3, 2006: Moderate to heavy rain experienced. Severe flooding occurred over the east-facing slopes of the Koolaus with significant damage in the Kaaawa, Hauula, and Punaluu areas.
- March 19, 2006: Strong thunderstorms dumped three to five inches of rain, mosly in a 6-hour period. Several properties were inundated in wets Oahu and, once again, along the north- and east-facing slopes of the Koolaus.
- March 23, 2006: Fast-moving thunderstorms swept over Honolulu and east Oahu during the evening of March 23 and caused considerable ponding in low lying areas such as Waikiki and another round of landslides in Tantalus.
- March 24, 2006: Strong, fast-moving thunderstorms hit Honolulu during the evening with 1- to 2-inch per hour rains producing more Tantalus landslides and causing the overflow of Makiki Stream near Fern Street and Moku Place.
- March 26, 2006: Heavy rains and flash flooding occurred on Oahu.
- March 31-April 2, 2006: Strong thunderstorms moved over the eastern half of the island during the late morning of March 31. The heavy rains coupled with very saturated ground produced severe runoff and flooding in several locations. Makiki Stream once again overflowed near Moku Place and inundated several blocks near Fern Street and Kalakaua Avenue. Manoa Stream overflowed at Woodlawn Drive.
- October 31, 2006 – November 2, 2006: Heavy rainfall occurred across much of Hawaii with rainfall amounts in some locations totaling over 15 inches. The excessive rains produced flooding over portions of windward Kauai and Oahu and triggered a significant landslide that closed Oahu's Pali Highway.
- December 10-14, 2008: Several rounds of rainfall occurred causing significant flooding. Several Oahu rain gauges recorded 10 to 13 inches in a 12-hour period.
- June 4, 2011: Strong thunderstorms produced intense rainfall and record-breaking stream flow over the windward slopes of Oahu. Flash floods from 5 to 10 inches of rain in a 3-hour period inundated roads and homes and severely damaged agricultural properties from Punaluu to Kailua. Emergency managers also report several rescues of people from stranded vehicles, but no deaths or serious injuries reported.
- April 13-15, 2018: Thunderstorms resulted in torrential rainfall and severe flooding over portions of Oahu.
- December 5-7, 2021: A kona low produced widespread heavy rainfall leading to flash flooding. Thunderstorms with heavy rainfall moved over Oahu from the south, causing flooding in numerous locations across the south side of the island and especially from Pearl City to Kahala. One notable impact was flooding damage to the Iwilei power substation which cut electrical service to Downtown Honolulu businesses and residents. Also, a section

of the H-1 Freeway westbound through Honolulu was closed due to waist-deep water near the Vineyard off ramp. On December 6, Mayor Rick Blangiardi of the City and County of Honolulu signed an Emergency Proclamation and Governor David Ige signed the "Heavy Rains and Flooding Proclamation for the State of Hawaii" due to the ongoing severe weather damaging public and private property. Based on both a precipitation frequency analysis and flow frequency analysis of gages within the basin, the storm event was characterized as approximately a 20% AEP—an event with a 20% chance of being equaled or exceeded in any given year—event.

Hydrologic and hydraulic modeling studies were conducted to estimate peak stream flow discharges and associated water surface elevations that could occur in the Ala Wai watershed because of a range of potential storm events, like those above. These models built upon previous modeling work and incorporated up-to-date topographic and hydro-meteorological data. More detailed information regarding the modeling assumptions, techniques, methodologies, results, and uncertainties can be found in Appendix B.

Hydrology

Hydrologic modeling was conducted to calculate peak flow discharges at key locations throughout the watershed. Discharge estimates for the 99%, 50%, 20%, 10%, 5%, 2%, 1%, 0.5%, and 0.2% AEP flood events were determined based on the results of various hydrologic methods that were used, depending on the location in the watershed and the availability of data. The main method used was the USACE HEC-HMS Version 4.3 hydrologic model. HEC-HMS Version 4.3 model results were compared with results from other regional methods, including the U.S. Geological Survey (USGS) regional peak-discharge regression equations, the CCH Drainage Standards Plate 6 curve, existing peak flow values from the FEMA Flood Insurance Study, and site-specific frequency analysis at USGWS gage locations using the USACE Hydrologic Engineering Center-Statistics Software Package (HEC-SSP). Regional methods are primarily dependent on drainage area and do not account for other physical or meteorological factors in the watershed, which can be accounted for in a HEC-HMS Version 4.3 model.

The resulting values for selected locations are shown in Table 17. As shown, the flow at the mouth of the Ala Wai Canal based on the 1% AEP flood event was computed to be 19,500 cubic feet per second (ft^3/s). Previous estimates of the 1% AEP peak flow value in this location ranged from 22,900 ft^3/s (Noda, 1994) to 28,200 ft^3/s (FEMA, 2004) and were based on regional methods. The current value is lower than previous estimates because of detailed modeling methods and accounting for channel and canal storage, which reduces the peak flow in the canal.

Table 17: Hydrologic Model Results for Peak Flow Discharge (ft^3/s) at Select Locations Within the Watershed at various percent probability events.

		Peak Flow Discharge (cfs)							
Watershed	**Location**	**2**	**5**	**10**	**20**	**50**	**100**	**200**	**500**

Hydraulics

Hydraulic modeling was conducted to estimate peak storm flow discharge as well as water surface elevations from peak discharge data and evaluate sensitivity to stage-discharge relationships in the Ala Wai watershed. Peak storm flow discharges (Table 18) and water surface elevations (Table 19) were estimated for the 50%, 20%, 10%, 5%, 2%, 1%, 0.5%, and 0.2% AEP flood events. The modeling was conducted using HEC-RAS and GIS software utilizing the best available data, using a one-dimensional, steady state flow model with sub-critical flow step-backwater computations. A detailed discussion on the methodology and assumptions used in the modeling effort is presented in Appendix B.

[1] Numbers shown are in cubic feet per second

Floodplain inundation maps were created for the 5% AEP (Figure 8), 2% AEP (Figure 9), and 1% AEP (Figure 10) flood events under the existing condition. Because of the relatively flat terrain around the Ala Wai Canal, the floodplain extents are similar for many of higher frequency storm events, with differences only in the depth of flooding. As further discussed in Appendix B, it is important to note that floodplain extent maps are a tool which help characterize the flood hazard but are not exact because of inherent limitations in the modeling process.

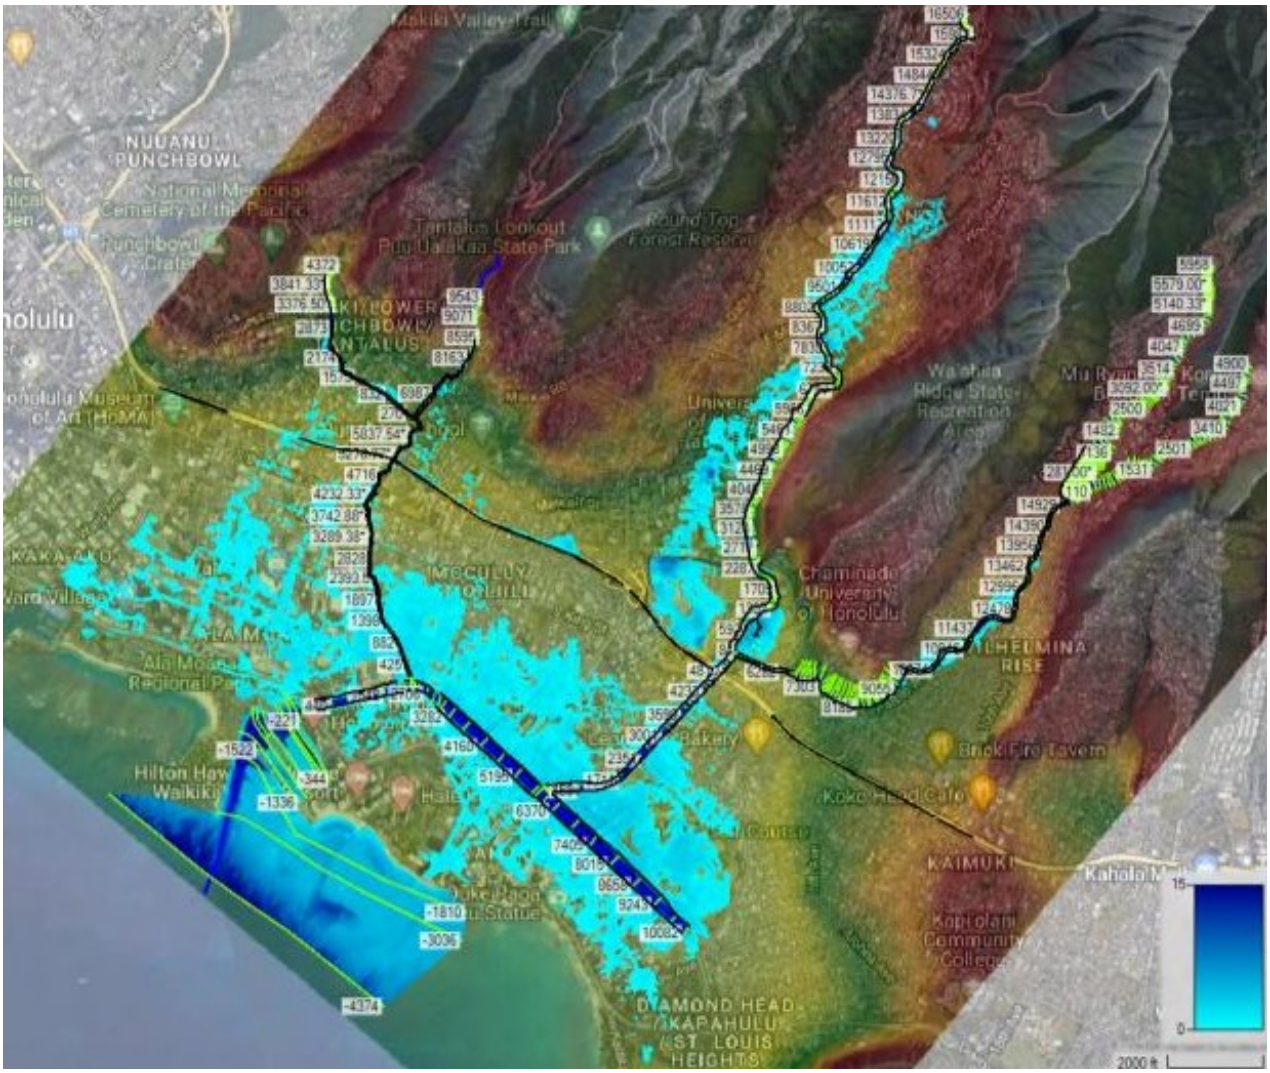

Figure 8: Existing Floodplain Inundation Map for the 5% AEP Flood Event.

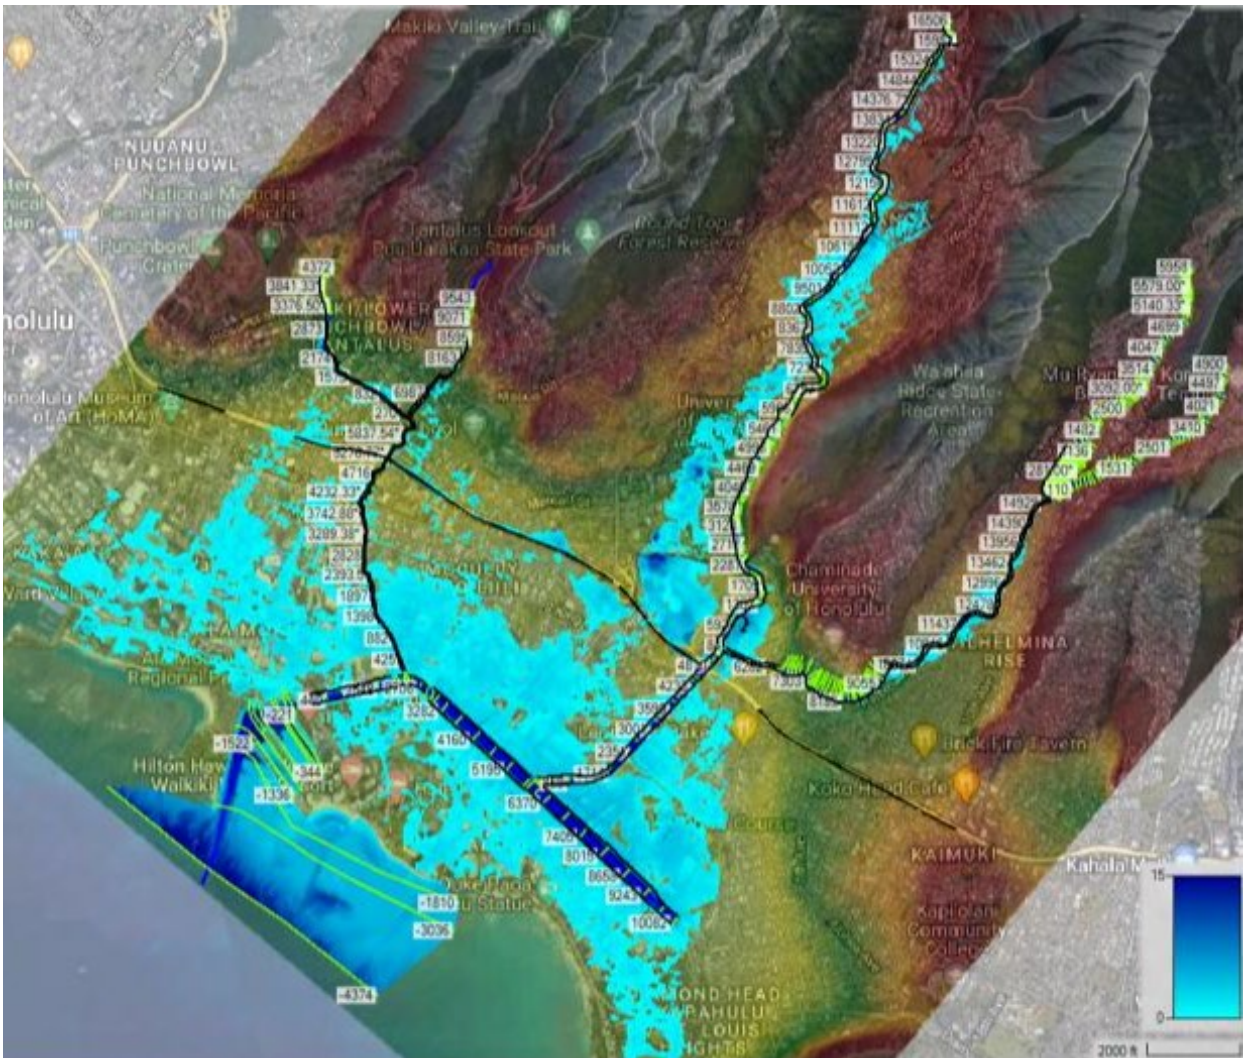

Figure 9: Existing Floodplain Inundation Map for the 2% AEP Flood Event.

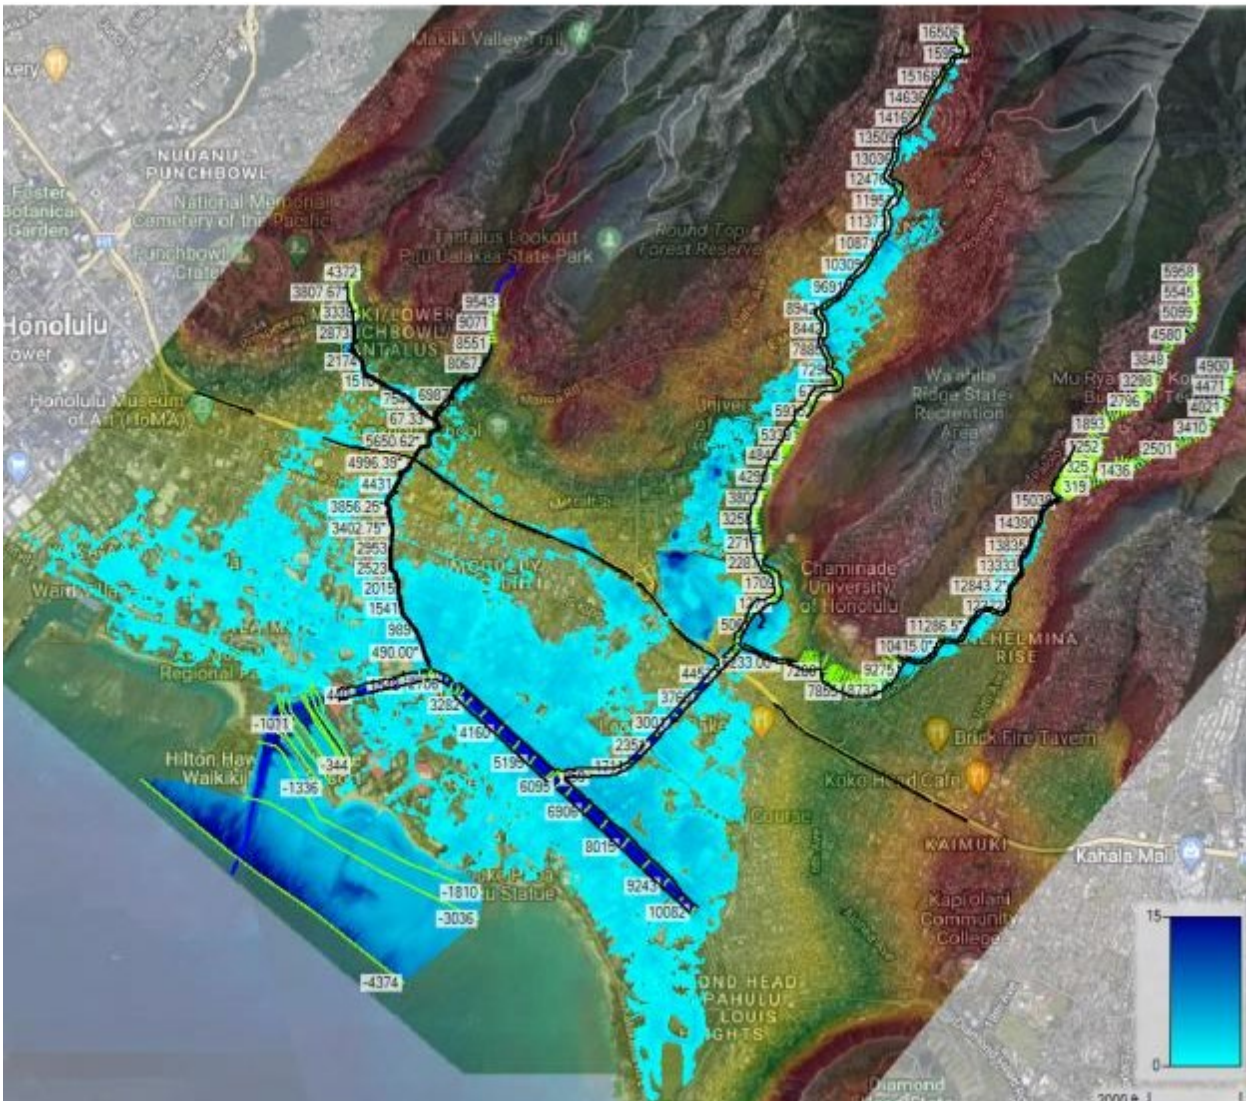

Figure 10: Existing Floodplain Inundation Map for the 1% AEP Flood Event.

Based on the 1% AEP flood event, a flow of approximately 3,475 ft^3/s leaves the system and flows into the ocean through Waikiki. Accounting for the effects of floodplain storage and the backwater along Makiki Stream, the peak flow at the mouth of the Canal is reduced from its upstream peak of 14,620 ft^3/s. This results in a greatly reduced flood inundation area between Kalakaua Avenue and Ala Moana Boulevard. Based on the peak flow values computed for this study, the Ala Wai Canal has about a 20% AEP flood capacity before overtopping the banks. This is less than the 10% AEP flood capacity documented by E.K. Noda (1994), even with the dredging completed in 2008. The reduced capacity may be because of the use of mean higher high water (MHHW) as a downstream boundary condition for all flood recurrence intervals and the use of a steady flow HEC-RAS model (which tends to be more conservative than the in-house model used by E.K. Noda [1994]). The McCully Street Bridge is the main reason for high water-surface elevations in the upstream sections of the Canal. The model results also indicate other key limitations in channel capacity, including the following:

- Makiki Stream has the lowest channel capacity of all the streams in the watershed. Flooding primarily occurs because high water surface elevations in the Ala Wai Canal cause water to back up into Makiki Stream and overtop the channel. Most of the flooding along Makiki

Stream occurs between King Stret and Kapiolani Boulevard. The elevations along Kapiolani Boulevard are slightly higher than the surrounding ground, and as a result, this feature acts as a weir preventing most of the flow from flooding the downstream area. A small area in the vicinity of Kaheka Street allows water to flow over Kapiolani Boulevard and eventually into the lower area of the parking facility of the Ala Moana Center.

- The confluence of Kanaha Ditch and Makiki Stream causes a backwater effect, which does not allow Kanaha Ditch to drain. Water overtops the channel, flows down slope across Wilder Street and floods the area approximately bounded by Kewalo Street and Keeaumoku Street. Flows are stopped at the H-1 Freeway where they would presumably drain into the stormwater drainage system.
- The model includes a detailed analysis of Palolo Stream which has not been previously available or documented on the FIRM. Results of the detailed modeling indicate a channel capacity capable of containing a 2% AEP flood event, with the section between Palolo Avenue Bridge to Kalua Road Bridge having a lower capacity (between 5% and 2% AEP flood event).
- Consistent with previous documentation (USACE, 2006; Oceanit, 2008), the modeling results indicate Manoa Stream has channel capacity limitations between Kahaloa Drive Bridge and Woodlawn Drive Bridge, which creates a flooding hazard for the nearby residences and the UH campus.

Flood depths for the 1% AEP flood event around the Ala Wai Canal, Manoa-Palolo Drainage Canal, and lower Makiki Stream are about 1.5 to 3 feet deep, on average, for the out of channel floodplain areas. Flood depths are about 2 to 3 feet deep, on average, for the split flow reaches of Kanaha and University overland flow areas. In upper Makiki, Manoa, and Palolo streams, flood depths may be up to 5 feet, depending on location.

Significance Criteria

Effects to hydrology and hydraulics would be considered significant if the proposed project would result in any of the following:

- Substantially alter the existing drainage pattern of the site or area.
- Substantially change drainage patterns within the watershed.
- Substantially increase the extent, frequency, or duration of flooding.
- Create or contribute to runoff that would exceed the capacity of existing or planned stormwater drainage systems.

Environmental Consequences

No Action

Significant Impact: Under the No Action Alternative, none of the flood risk management measures would be implemented, such that the existing flood-related threats would remain. In addition, future climate changes are expected to contribute to increased water surface elevations due to sea-level rise.

Extensive urban development throughout the Ala Wai watershed, coupled with the basin's unique topography and hydrology (i.e., steep mountainous terrain and propensity for intense rainfall events within the headwaters) would continue to result in an elevated flood risk for a large proportion of the population both along the Ala Wai Canal and within the Makiki, Manoa, and Palolo valleys without implementation of flood risk management measures. Past flooding that has occurred within the watershed has resulted in property damages and health and safety risks. These risks are expected to remain under the No Action alternative. The potential impact

of flooding could be significant. Analyses conducted in support of this study show that the 1% AEP flood event—an event with a 1% chance of being equaled or exceeded in any given year—could affect approximately 3,111 structures with an estimated $905,327,000 in structural damages alone (2023 price levels). This figure does not account for loss in business income or other similar economic losses. Safety risks in the event of flooding would also remain under the No Action alternative. The Ala Wai watershed has approximately 200,000 residents that would remain under threat of flooding. The watershed also contains the University of Hawaii and the Waikiki District—a prime tourist destination that attracts more than 79,000 visitors per day and accounts for approximately 8% of the gross state product and 11% of all civilian jobs in the state. Overall, under the No Action alternative, local flooding issues would continue in the manner as they currently occur. Under existing conditions, the 20%, 10%, 4%, 2%, 1%, 0.5%, and 0.2% AEP events cause flooding in the overbanks including comingling flooding between the channel systems. Widespread flooding begins at approximately the 10% AEP flood event throughout the study area and is caused by overtopping of the channels. Widespread overtopping of the channels would still occur between the 10% and 0.2% AEP events within the Ala Wai watershed, thereby leaving homes and businesses at risk to impacts from flooding.

Current water quality issues associated with storm water and with flood events would remain unchanged under the No Action Alternative. No new water quality issues would be introduced, and no water quality issues would be addressed.

Consistent with the USACE EC 1165-2-212 and ECB 2013-27, three scenarios (low, intermediate, and high) were modeled to define the future without-project hydrologic and hydraulic conditions, with each scenario defined based on the corresponding rate of change in the input conditions. Low is considered the best-case scenario (with a continuation in the current trends for sea-level rise and rainfall intensity), intermediate is the most probable scenario, and high is considered the worst-case scenario. The modeling inputs for these three scenarios are summarized in Table 20. Refer to Appendix H for a detailed discussion sea level change.

Table 20: Future Without-Project Scenario for Sea Level Change by 2080.

Component	Low	Intermediate (Most Probable)	High
Sea Level Rise	+ 0.43 ft	+ 1.12 ft	+ 3.31 ft

Alternative 1

Less than Significant Impact with Mitigation Incorporated: The overall objective of the project is to reduce the risk of riverine flooding. Therefore, Alternative 1 has been designed to detain floodwaters and/or improve conveyance to minimize the risk of flooding within the watershed. Construction of the project is primarily on land with work near/in water required just for drainage structures. Where in water work may need to occur a coffer dam or similar type structure would be constructed, but the sizes of these structures would be small and would not be expected to substantially alter the existing drainage pattern of a site or area not substantially change drainage pattern within the watershed. The long-term operation and maintenance of the project, including maintenance of pump station(s) if determined to be necessary, would have a similar effect as the short-term effects on drainage patterns in the area. Overall, short-term, and long-term negligible adverse effects to drainage patterns in the area and/or watershed would occur. The 5%, 2%, and 1% AEP floodplain inundation maps for Alternative 1 are shown in Figure 11, Figure 12, and Figure 13. Anticipated peak flow discharges and surface water elevations for the 5%, 2%, and 1% AEP floodplains are shown in Table 21. Model results for other APE probabilities are presented in Appendix B.

[1] Numbers shown for peak flow discharge are in cfs while water numbers shown for water surface elevation are in feet.

The outlets draining the detention basins proposed under Alternative 1 are generally designed to pass all flows under 10% to 20% AEP; in other words, 80% to 90% of all expected flow events will pass without increase to inundation beyond existing conditions. However, less frequent events such as the 0.2% AEP increase the extent of flooding beyond the extent that currently occurs under existing condition. Since the proposed project would cause induced flooding where it does not always occur under the existing condition, mitigation measures would need to be implemented to minimize the impacts of induced flooding. Nonstructural mitigation measures currently under consideration but not yet fully developed include dry/wet floodproofing (EC HH-2), elevation (EC HH-3), and buy outs (EC HH-4). For a discussion of the potential impacts to hydrology and hydraulics refer to Alternative 6 which includes similar nonstructural measures. The only structural measure currently under consideration, but unlikely to be implementable, is the construction of a pump station(s) located along Makiki Stream where most induced flooding is occurring (EC HH-1). The pumping station would mitigate for interior flooding that could be induced by the floodwalls during a storm event. The number and precise location of a permanent pump station(s) is unknown at this time; however, the pumping capacity that would be needed ranges between 500 and 20,000 cubic feet/second (cfs), which would be a large pump station(s). A permanent pump station(s) would likely consist of a wet well installed in a low-lying area where water naturally flows. The wet well would consist of a concrete inlet box with mesh screens for debris and wildlife protection, hinged lid for pump removal for maintenance, etc. The outlet from the wet well would be routed to the floodwall and would either pass over the wall or through it with a check valve to prevent inflow from the river side. The wet well would connect to a pump house. The pump house would be elevated and would hold the electrical infrastructure and other operating equipment, and a backup generator to minimize pump failure in the event of power disruption. The pumps (if necessary) would be designed to mitigate for induced flooding; however, pumps alone would not fully mitigate for induced flooding. The precise size and location of a pump station(s), if found to be necessary, and design would be analyzed during the Preconstruction Engineering and Design (PED) phase. Therefore, implementation of Alternative 1 would have long-term significant adverse effects to surface water by increasing the extent of flooding in some areas during less frequent storm events. Conversely, there would also be long-term beneficial effects to hydrology and hydraulics with the implementation of Alternative 1 which would also minimize the extent of flooding in some areas as well as potentially remove flooding potential for some areas in the watershed. Even though there could be a benefit for some areas in the watershed, the mitigation measures discussed above (i.e., nonstructural and pump station(s)) would need to be implemented to offset significant adverse impacts to those areas that would experience induced flooding.

The proposed project is designed to detain in-stream flows and/or improve conveyance within the stream channels, such that it is not expected to affect the quantity of stormwater runoff or the capacity of the stormwater drainage system. By reducing the floodplain, the proposed project would reduce the extent of the stormwater drainage system that is subject to inundation. Overall, the implementation of Alternative 1 would have short-term negligible adverse effects to hydrology and hydraulics. Long-term beneficial effects to hydrology and hydraulics are expected by minimizing the extent of flooding in some locations. However, long-term significant adverse effects to hydrology and hydraulics are also expected due to less frequent storm events causing flooding where it does not occur under the existing condition (i.e., induced flooding). The implementation of mitigation measures EC HH-1 through EC HH-4, which are still being explored, are anticipated to reduce this significant adverse impact to a less than significant adverse impact.

Alternative 2B

Less than Significant Impact with Mitigation Incorporated: In general, the type of project features included in Alternative 2B would have similar construction, operation, maintenance, and mitigation requirements as Alternative 1, such that the nature and degree of potential impacts to hydrology and hydraulics are generally expected to be similar. Therefore, refer to the analysis under Alternative 1 for Alternative 5.3 project impacts. Differences in the reduction of flood risk between Alternative 2B and Alternative 1 are discussed below.

Like Alternatives 1, Alternative 2B would minimize the occurrence of flooding within various areas of the watershed for frequent storm events. The minimization of flooding under Alternative 2B is less than that provided with Alternative 1. Also, like Alternative 1, the proposed project would induce flooding within the watershed in various areas that currently do not experience flooding. Induced flooding would be greater than that experienced under Alternative 1 and would be anticipated to occur only during large storm events that occur less frequently. The 5%, 2%, and 1% AEP floodplain inundation maps for Alternative 2B are shown in Figure 14, Figure 15, and Figure 16. Anticipated peak flow discharges and surface water elevations for the 5%, 2%, and 1% AEP floodplains are shown in Table 22. Model results for other APE probabilities are presented in Appendix B.

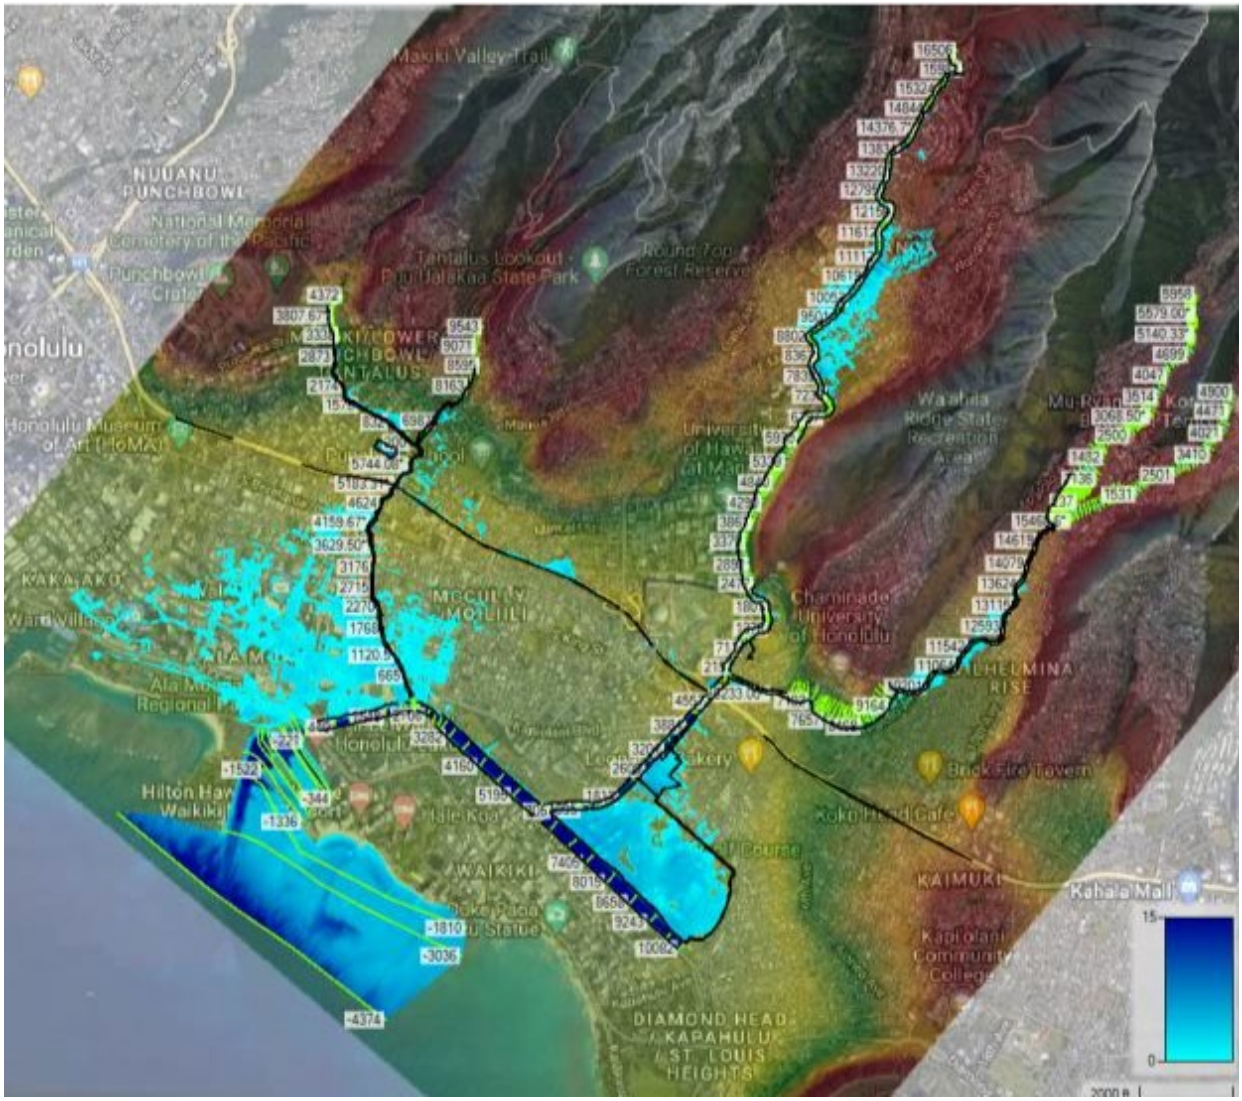

Figure 14: Alternative 2B Floodplain Inundation Map for the 5% AEP Flood Event.

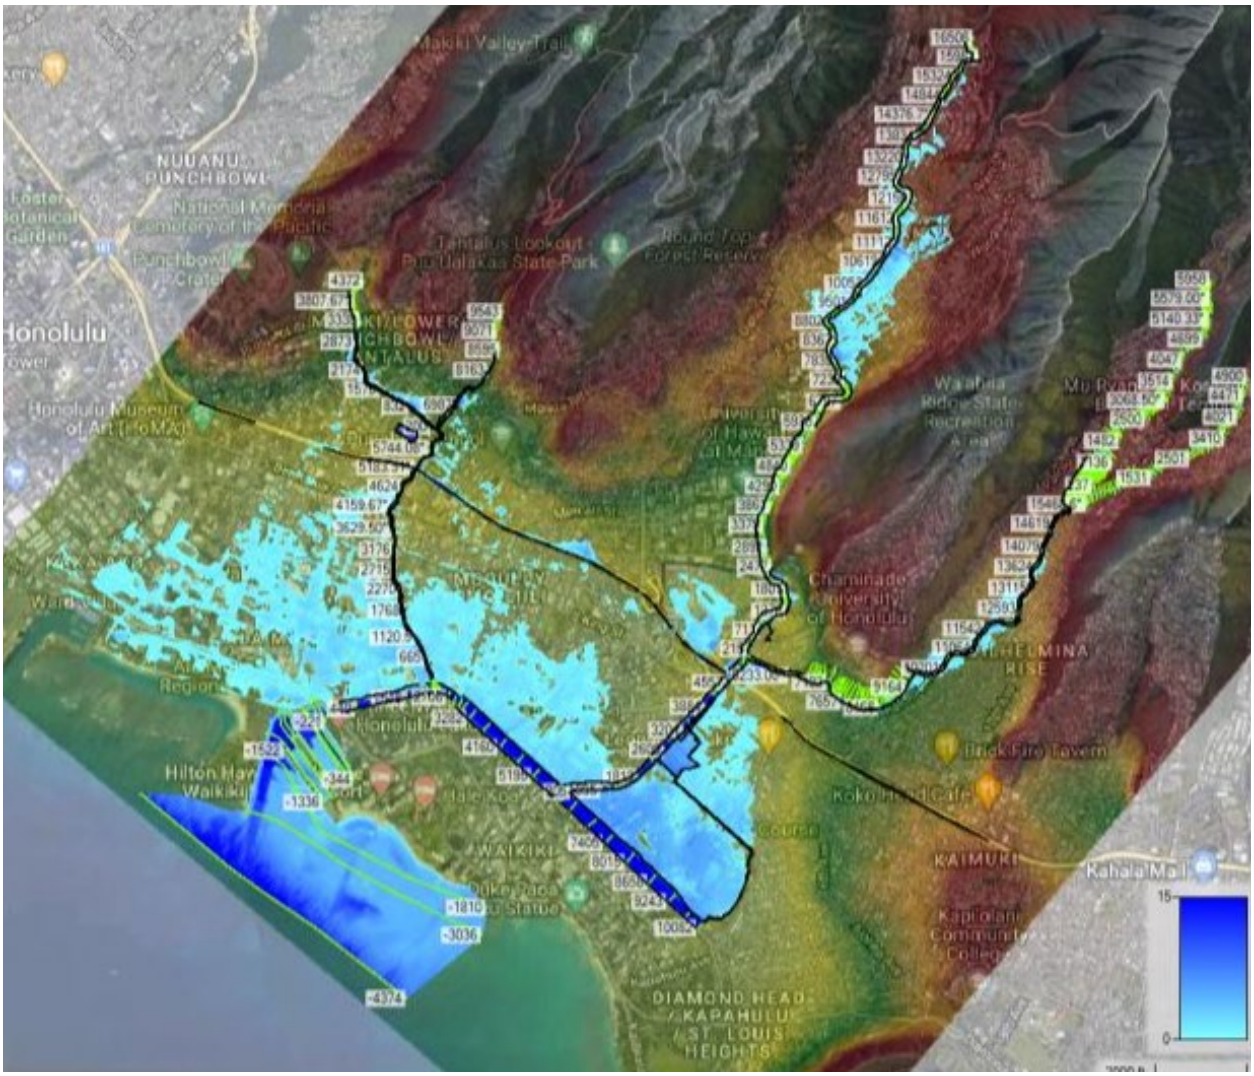

Figure 15: Alternative 2B Floodplain Inundation Map for the 2% AEP Flood Event.

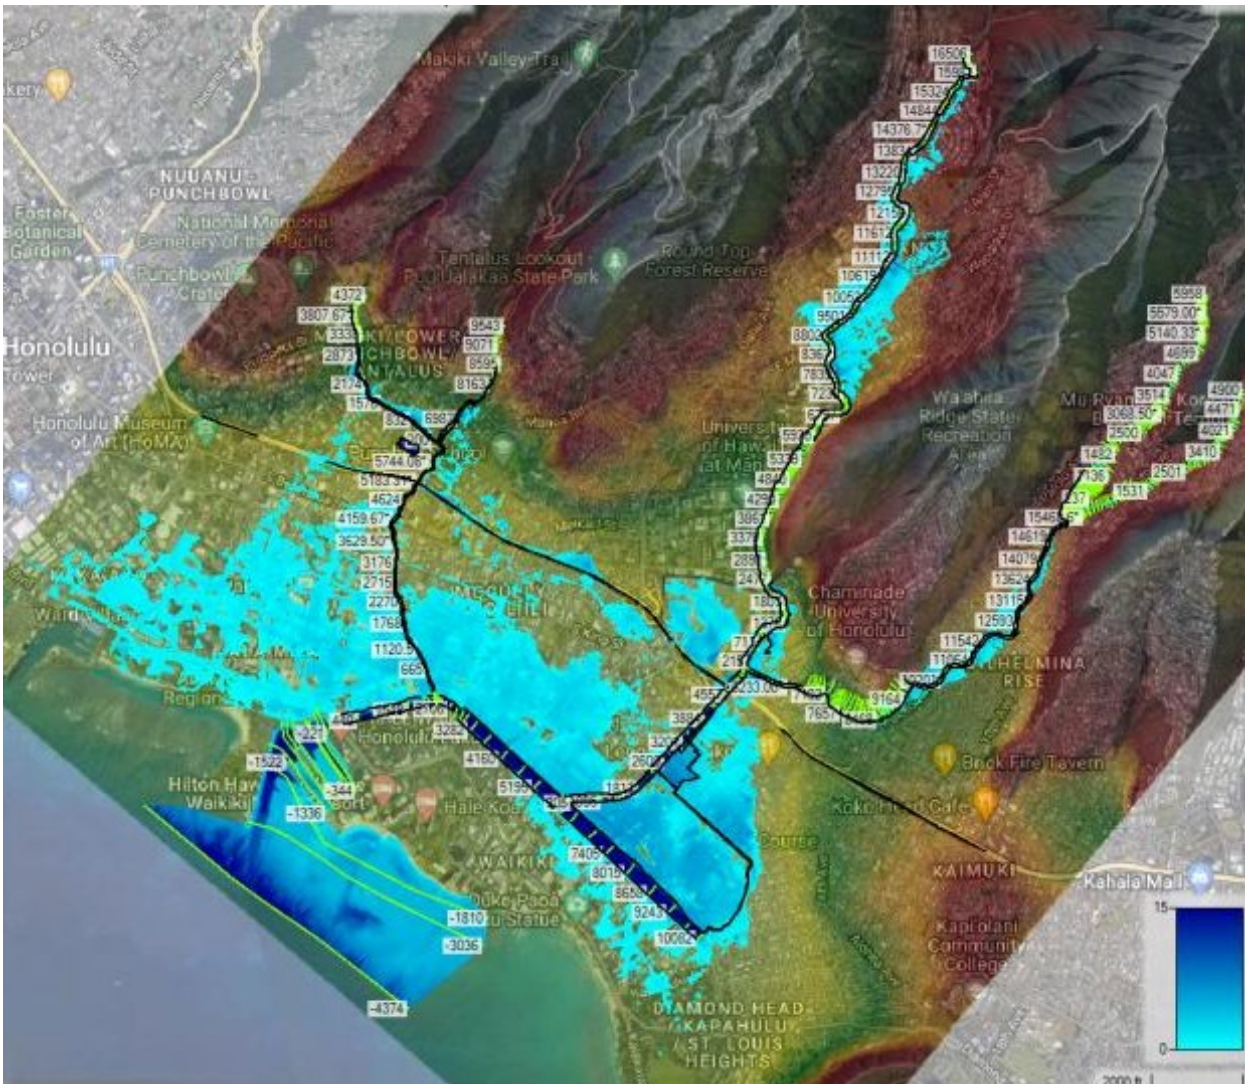

Figure 16: Alternative 2B Floodplain Inundation Map for the 1% AEP Flood Event.

The overall potential for flood damage reduction associated with Alternative 2B is not expected to be as great as that associated with Alternative 1. However, Alternative 2B is still expected to provide a significant beneficial impact relative to reduced potential for flooding in the watershed, especially for less frequent events.

Overall, the implementation of Alternative 2B would have short-term negligible adverse effects to hydrology and hydraulics. Long-term beneficial effects to hydrology and hydraulics are expected by minimizing the extent of flooding in some locations. However, long-term significant adverse effects to hydrology and hydraulics are also expected due to less frequent storm events causing flooding where it does not occur under the existing condition (i.e., induced flooding). The implementation of mitigation measures EC HH-1 through EC HH-4, which are still being explored, are anticipated to reduce this significant adverse impact to a less than significant adverse impact.

[1] Numbers shown for peak flow discharge are in cfs while water numbers shown for water surface elevation are in feet.

Overall, the implementation of Alternative 5.3 would have short-term negligible adverse effects to hydrology and hydraulics. Long-term beneficial effects to hydrology and hydraulics are expected by minimizing the extent of flooding in some locations. However, long-term significant adverse effects to hydrology and hydraulics are also expected due to less frequent storm events causing flooding where it does not occur under the existing condition (i.e., induced flooding). The implementation of mitigation measures EC HH-1 through EC HH-4, which are still being explored, are anticipated to reduce this significant adverse impact to a less than significant adverse impact.

Alternative 6

No Impact: Implementation of Alternative 6 would not have any short-term or long-term direct or indirect impacts on hydrology or hydraulics because construction would be occurring to existing structures and nothing within a waterway or nearshore.

Environmental Commitments

The following environmental commitments could potentially be implemented minimize induced flooding under Alternatives 1, 2B, and 5.3.

EC HH-1: Potential pump station(s) located within the vicinity of Makiki Stream to minimize induced flooding. The location, size, and number of pumps that may be required will be analyzed and detailed during PED. Generally, due to the cost of this mitigation measure it is highly unlikely that this proposed mitigation measure would be implemented.

EC HH-2: Dry and/or wet floodproofing commercial structures in areas where induced flooding occurs. The number of structures and the location of structures that would need to be dry and/or wet floodproofed will be analyzed and detailed during PED.

EC HH-3: Elevating residential structures in areas where induced flooding occurs. The number of structures and the location of structures that would need to be elevated will be analyzed and detailed during PED.

EC HH-4: Acquisition of commercial and/or residential structures in areas where induced flooding occurs. The number of structures and the location of structures that would need to be acquired will be analyzed and detailed during PED.

Best Management Practices

No specific BMPS associated with impacts to hydrology and hydraulics apply. Refer to BMPs for water quality that would also be applicable to hydrology and hydraulics.

3.3.7 Water Quality

Regulatory Setting

Relevant federal and state laws/regulations include:

- Clean Water Act, Sections 401 and 402
- HAR Chapter 11-54 (Water Quality Standards)
- Chapter 11-55 (Water Pollution Control)

Existing Conditions

Under Section 303(d) of the Clean Water Act, states, territories, and authorized tribes are required to develop and update every two years, lists of waters – rivers, lakes, coastal waters, and estuaries – that are impaired (or threatened) by one or more pollutants. Total Maximum Daily Loads (TMDL's) must then be prepared for all waters on the 303(d) List. Figure 20 and Table 24 show the pollutants for which Makiki, Palolo, Manoa, Ala Wai Canal and Harbor have been placed on the 303(d) List of Water Quality Limited Segments. Manoa stream (State Waterbody ID: HI3-3-07.01) is listed as impaired for aquatic life and other due to murky water, nitrogen and/or phosphorous, and pesticides (USEPA, 2022b). Makiki stream (State Waterbody ID: HIALWS06) is listed as impaired for aquatic life due to nitrogen and/or phosphorus. Palolo stream (State Waterbody ID: HI3-3-07.01.1) is listed as impaired for aquatic life due to trash. Ala Wai Canal and Harbor (Palolo Stream Fork) (State Waterbody ID: HIW00034) is listed as impaired for aquatic life, swimming and boating, and other due to bacteria and other microbes, murky water, and nitrogen and/or phosphorus. Ala Wai Canal and Boat Harbor (State Waterbody ID: HIW00050) is listed as impaired for aquatic life, swimming and boating, and other due to bacteria and other microbes, metals, murky water, nitrogen and/or phosphorus, pesticides, and other unknown causes. The following three TMDL's have been developed to protect and restore water quality within the Ala Wai Canal: Ala Wai Canal Phosphorus (January 1, 2002 – addresses algal growth and nutrient impairments), Ala Wai Canal Suspended Solids (February 21, 1986 – addresses suspended solids impairment), and Ala Wai Canal Toxic Pollutants (February 21, 1986 – addresses unlisted impairments). Kahanamoku Lagoon (State Waterbody ID: HIW00003) is listed as impaired for swimming and boating due to bacteria and other microbes. Kahanamoku Beach (State Waterbody ID: HI366432) is listed as impaired for aquatic life due to algae and murky water. Royal-Moana Beach (State Waterbody ID: HI898947) is listed as impaired for aquatic life due to algae, ammonia, murky water, and nitrogen and/or phosphorus. Waikiki Beach Center (State Waterbody ID: HI244505) is listed as impaired for aquatic life due to murky water (USEPA, 2022b).

Figure 20: Location of 303(d) Listed Water Quality Limited Segments within the Ala Wai Canal Watershed.

Table 24: Ala Wai Canal Watershed 303(d) Listed Pollutants for Water Quality Limited Segments.

Area (miles[a] or square miles[a])	Impairment	Total Maximum Daily Load (TMDL) Developed	Probable Sources Contributing to Impairment from 2020
Manoa Stream (11.3 miles)	Chlordane	No	Unknown
Manoa Stream (11.3 miles)	Dieldrin	No	Unknown
Manoa Stream (11.3 miles)	Nitrate/Nitrite	No	Unknown
Manoa Stream (11.3 miles)	Total Nitrogen	No	Unknown
Manoa Stream (11.3 miles)	Total Phosphorus	No	Unknown
Manoa Stream (11.3 miles)	Turbidity	No	Unknown
Makiki (7.4 miles)	Total Nitrogen	No	Unknown
Makiki (7.4 miles)	Total Phosphorus	No	Unknown
Palolo Stream (8.7 miles)	Trash	No	Unknown
Ala Wai Canal and Harbor (Palolo Stream Fork) (0.003 square miles)	Turbidity	No	Unknown
Ala Wai Canal and Harbor (Palolo Stream Fork) (0.003 square miles)	Total Nitrogen	No	Unknown
Ala Wai Canal and Harbor (Palolo Stream Fork) (0.003 square miles)	Fecal Coliform	No	Unknown
Ala Wai Canal and Boat Harbor (0 square miles)	Cause Unknown	No	Unknown
Ala Wai Canal and Boat Harbor (0 square miles)	Lead	Yes	Unknown
Ala Wai Canal and Boat Harbor (0 square miles)	Nitrate/Nitrite	No	Unknown
Ala Wai Canal and Boat Harbor (0 square miles)	Total Nitrogen	No	Unknown

Area (miles[a] or square miles[a])	**Impairment**	**Total Maximum Daily Load (TMDL) Developed**	**Probable Sources Contributing to Impairment from 2020**
Ala Wai Canal and Boat Harbor (0 square miles)	Nutrients	No	Unknown
Ala Wai Canal and Boat Harbor (0 square miles)	Total Phosphorus	Yes	Unknown
Ala Wai Canal and Boat Harbor (0 square miles)	Total Suspended Solids	Yes	Unknown
Ala Wai Canal and Boat Harbor (0 square miles)	Turbidity	No	Unknown
Ala Wai Canal and Boat Harbor (0 square miles)	Pesticides	No	Unknown
Ala Wai Canal and Boat Harbor (0 square miles)	Enterococcus	No	Unknown
Kahanamoku Lagoon (0.25 square miles)	Enterococcus	No	Unknown
Kahanamoku Beach (0.3 miles)	Chlorophyll a	No	Unknown
Kahanamoku Beach (0.3 miles)	Turbidity	No	Unknown
Royal-Moana Beach (0.4 miles)	Ammonia-Nitrogen	No	Unknown
Royal-Moana Beach (0.4 miles)	Chlorophyll a	No	Unknown
Royal-Moana Beach (0.4 miles)	Nitrate/Nitrite	No	Unknown
Royal-Moana Beach (0.4 miles)	Turbidity	No	Unknown
Waikiki Beach Center (0.05 miles)	Turbidity	No	Unknown

[a] refers to the miles or square miles assessed

The City and County of Honolulu National Pollutant Discharge Elimination System (NPDES) Municipal Separate Storm Sewer System (MS4) Permit No. HI S000002 was issued by the State of Hawaii, Department of Health (DOH) and became effective on September 1, 2020 (City and County of Honolulu, 2021). The permit will expire on August 31, 2025. Pursuant to Part F.1(a) of the Permit, a monitoring program must be designed and implemented. The overarching goal for the monitoring program required under the MS4 is related to both managing and assessing the effectiveness of the Storm Water Management Program (SWMP). The primary objective of the SWMP is to reduce to the maximum extent practicable, pollutants discharged from the City and County of Honolulu's MS4 to State waters, and to evaluate monitoring data (City and County of Honolulu, 2021).

Significance Criteria

Effects to water quality would be considered significant if the proposed project would result in any of the following:

- Substantially degrade surface water quality such that it would violate water quality standards, contribute to exceedance of aquatic life guidelines, or otherwise impair beneficial uses.
- Substantially increase contaminant levels in the groundwater.

Environmental Consequences

No Action

No Impact: Under the No Action Alternative, none of the flood risk management measures would be implemented. The potential future without project condition assumptions are the same as those discussed in the 2017 Ala Wai Canal Study (USACE, 2017); therefore, that discussion is incorporated by reference.

Alternative 1

Less than Significant Impact: Construction of Alternative 1 features, primarily the inlet and outlet structures associated with the detention basins, could increase the delivery of sediment (i.e., from construction-related erosion) and associated pollutants via stormwater runoff, which could temporarily affect water quality in the streams and downstream receiving waters. Although sediment-bound pollutants are known to occur throughout the watershed (particularly in the urbanized areas), none of the soils that would be exposed by construction are expected to contain excessive levels of contamination. In general, construction of the flood risk measures would involve placement of imported materials, with only minimal amounts of excavation. All materials used to construct the measures would be from approved sources and would be clean and free of contaminants. Areas requiring excavation (e.g., Makiki District Park Detention Basin, Manoa Valley District Park Detention Basin, and the inlet and outlet structures associated with these detention basins and the Ala Wai Golf Course Detention Basin) are located in open space areas, which are not subject to significant inputs of roadways sediments or other anthropogenic contaminants, such that a significant increase in pollutant delivery to the receiving streams would be expected as a result of construction.

During construction, storage and use of some hazardous materials would occur. If handled inappropriately, these materials could accidentally spill or inadvertently discharge to adjacent waterways or groundwater. Construction activities would involve the use of heavy equipment, cranes, compactors, and other construction equipment that use petroleum products such as fuels, lubricants, hydraulic fluids, and coolants, all of which are detrimental to water quality. BMPs listed below would be implemented to minimize the risk of inadvertent spills.

Construction would disturb more than 1 acre of land; therefore, the project would be regulated under the State's NPDES stormwater program, which requires the preparation of a SWPPP to obtain permit coverage. The objective of a SWPPP is to describe the measures that would be implemented to prevent sedimentation, erosion, and stormwater contamination, in compliance with the requirements of the NPDES program. BMPs that would be implemented to minimize impacts associated with potential pollutants are listed below. Preparation and implementation of the SWPPP, as well as adherence to other requirements of the NPDES program, would reduce the potential construction-related water quality impacts to less than significant and no mitigation would be required.

The operation and maintenance of Alternative 1 is not expected to contribute pollutants to the waterways or otherwise measurably effect water quality. The inlet structures to the detention basins are designed to divert water into the detention basins starting at the 5% AEP flood event. Diverted water would be held in the detention basins until stormwater flows begin to dissipate, at which time detained water would be slowly released back into the receiving streams. During the detention of water within the basins, sediments within the water column would likely settle out, meaning water leaving the detention basins could contain less sediment than water that entered the detention basins. However, the degree to which sediments would settle out and the reduction of sediments within detained water flowing back into the stream is unknown. It's important to note that the detention basins are generally located within areas that are already subject to flooding under the existing without project condition, such that the implementation of Alternative 1 is not expected to substantially increase delivery of contaminants to the streams beyond that which already occurs or otherwise alter the location or degree of water quality contaminants.

Maintenance activities could involve the use of machinery to remove debris from the inlet/outlet structures and the detention basins as well as to potentially repair any erosion that might occur near the inlet/outlet structures. Like construction, heavy equipment which requires the use of petroleum products that are detrimental to water quality, may be needed for maintenance activities. BMPs implemented during construction would also be implemented during maintenance activities to minimize the risk of inadvertent spills. Therefore, with the implementation of BMPs, the project is expected to have a less than significant impact on water quality.

Alternative 1 also includes the implementation of mitigation measures for induced flooding. Nonstructural measures like dry/wet floodproofing, elevation, and acquisition would have similar impacts to water quality as the Nonstructural Alternative that was analyzed. Therefore, refer to the discussion under Alternative 6 for the potential effects to water quality these potential mitigation measures would cause. The only structural mitigation measure being considered is permanent pump station(s), although due to cost the construction of pump station as a mitigation measure is highly unlikely. If constructed, though, a pump station would only operate during a storm event. The primary purpose of the pump station would be to minimize induced flooding on structures located outside the floodwalls where modeling has found induced flooding to be probable. If necessary, permanent pump stations are intended to collect rainfall and stormwater runoff that is not collected by the subsurface drainage system as it naturally flows to low-lying areas. The runoff would be pumped over/through the floodwall before water levels elevate to a level of inducing flooding to nearby structures. The pumps would not redirect runoff; they would move it where it would have drained without the floodwall. When operating, the pump station(s) would serve as a long-term point source of stormwater discharge. The potential pump station(s) would be expected to be compliant with state water quality standards. In addition, a small, manufactured treatment device or sediment settling basin would be installed

as part of the pump station(s). Therefore, long-term the hydraulic pumps could influence the quality of stormwater runoff, but it would be temporary, minor, and not significant.

Alternative 2B

Less than Significant Impact: In general, the type of project features included in Alternative 2B would have similar construction, operation, maintenance, and mitigation requirements as Alternative 1, such that the nature and degree of potential impacts to water quality are generally expected to be similar. Therefore, refer to the analysis under Alternative 1 for Alternative 2B project impacts. Overall, Alternative 2B would have a short-term less than significant adverse effect to water quality. Alternative 2B would also have a long-term less than significant adverse effect to water quality.

Alternative 5.3

Less than Significant Impact: In general, the type of project features included in Alternative 5.3 would have similar construction, operation, maintenance, and mitigation requirements as Alternative 1 and Alternative 2B, such that the nature and degree of potential impacts to water quality are generally expected to be similar. Therefore, refer to the analysis under Alternative 1 and Alternative 2B for Alternative 5.3 project impacts. Overall, Alternative 5.3 would have a short-term less than significant adverse effect to water quality. Alternative 5.3 would also have a long-term less than significant adverse effect to water quality in addition to a long-term beneficial effect to water quality.

Alternative 6

No Impact: No short-term direct or indirect water quality impacts would occur as a result of implementation of Alternative 6 because land disturbance for this alternative would be limited to modification of existing buildings. Implementation of Alternative 6 would require temporary construction access to all structures to be treated, but this is expected to occur from existing roads. Similarly, localized maintenance such as repairs would be needed over time. Overall, no direct or indirect long-term adverse effects to water quality would occur as a result of this alternative. Appropriate erosion and sediment control measures would be utilized during construction.

Environmental Commitments

No specific environmental commitments associated with impacts to water quality apply.

Best Management Practices

Implementation of the following BMPs would help ensure that effects on water quality and WOTUS would remain at less than significant levels. Standard BMPs include:

- Appropriate erosion control measures would be incorporated into the SWPPP by the construction contractor to prevent sediment from entering waterways and to minimize temporary turbidity impacts. Examples include, but are not limited to, strawbales/wattles, erosion blankets, silt fencing, silt curtains, mulching, revegetation, and temporary covers. Sediment and erosion control measures would always be maintained by the contractor during construction. Control measures would be inspected periodically by the construction contractor, particularly during and after significant rain events.
- A fuel spill management plant would be developed for the project by the construction contractor and would be implemented by the contractor.
- Construction equipment and vehicles would be fueled and maintained in specific staging areas only, which would be designed to capture potential spills. These areas cannot be

near any ditch, stream, or other body of water or feature that may convey water to a nearby body of water.
- Any spills of hazardous material would be cleaned up immediately by the construction contractor.
- Construction vehicles and equipment would be inspected frequently and appropriately maintained by the construction contractor to help prevent dripping of oil, lubricants, or any other fluids.
- Implementation and adherence to any additional requirements as mandated by the Construction General Permit and the Section 401 Water Quality Certification. The construction contractor would obtain the Construction General Permit while USACE would obtain the Section 401 Water Quality Control Certification. The contractor would be responsible for implementing requirements set forth in these two permits.

3.3.8 Sediment Quality

Regulatory Setting
Relevant federal and state laws/regulations include:
- Clean Water Act, Section 401, Section 402, and Section 404

Existing Conditions
No systematic studies of sediment quality have been completed for the Ala Wai watershed; however, a few studies have been conducted in conjunction with water quality and environmental condition assessments. Sediment quality within the Ala Wai watershed, most notably in the Manoa watershed, has been negatively impacted by intensive historical use of herbicides in Hawaii, year-round cultivation practices, prevalence of subterranean termites, and proximity of agricultural and residential lands to streams (Spengler et al., 2019). In general, the sediment quality correlates with urban land uses. Elevated levels of organochlorine pesticides (e.g., dieldrin, chlordane, and dichloro-dephenyl-trichloroethane [DDT]), polychlorinated biphenyls (PCBs) and semivolatile organic compounds and polycyclic aromatic hydrocarbons (PAHs) have all been detected in the stream sediments of the Manoa watershed at concentrations exceeding the aquatic-life guidelines (USGS, 2004). Concentrations of barium, cadmium, lead, tin and zinc were also found to be higher in urban areas than in the undeveloped forested basins, which suggests human sources of these elements (USGS, 2004).

Significance Criteria
Effects to sediment quality would be considered significant if the proposed project would result in any of the following:
- Substantially increase contaminant concentrations within the watershed by mobilizing buried contaminants.

Environmental Consequences

No Action
No Impact: Under the No Action Alternative, none of the flood risk management measures would be implemented. During heavy rainfall events, the rapid rise in stream volumes would be expected to continue mobilizing contaminated streambed sediments and re-suspending the sediments within the water column, consistent with current conditions.

Alternative 1

Less than Significant Impact: The construction of Alternative 1 features, especially the inlet and outlet structures associated with the detention basins, could disturb contaminated streambed sediments where the features connect to the receiving stream. Although sediment-bound pollutants are known to occur throughout the watershed (particularly in the downstream urbanized areas), sediment that must be removed for the installation of inlet and outlet structures would be disposed of upland (not placed in channel). The stream channel and banks near inlet and outlet structures would be stabilized by the use of riprap, vegetation, or similar means. Typically, less than 0.02 acre of streambed sediments would have the potential of being disturbed and potentially mobilized with the construction of the inlet/outlet structures. Other features that are part of Alternative 1 like floodwalls and road closure structures, would not include construction within a stream channel. Therefore, construction of these features would have no potential for disturbing potentially contaminated streambed sediments.

Long-term, the operation and maintenance of the detention basins are not expected to substantially increase contaminant concentrations within the watershed by mobilizing buried contaminants. The inlet structures to the detention basins are designed to divert water into the detention basins starting at the 5% AEP flood event. Diverted water would be held in the detention basins until stormwater flows begin to dissipate, at which time the detained water would be slowly released back into the receiving streams. During the detention of water within the basins, streambed sediments that were mobilized due to high stream volumes during a heavy rainfall event, would be expected to have time to settle out within the detention basins. This means water leaving the detention basins could contain less sediment and potentially contaminated sediments, than the water that was entrained in the basins. However, the degree to which sediments would settle out and the reduction of sediments within the entrained water flowing back into the stream is unknown.

Maintenance activities could include debris removal from the inlet and outlet structures and removal of sediment and debris from the detention basins. The removal of debris from the inlet and outlet structures could potentially disturb streambed sediments, although the area potentially disturbed during debris removal would be less than the acreage disturbed during the construction of the inlet/outlet structures. Any debris and sediment removed from the inlet/outlet structures and detention basins would be disposed of at an approved upland facility.

Alternative 1 also includes the implementation of mitigation measures to minimize induced flooding caused by the proposed project. Nonstructural measures like dry/wet floodproofing, elevation, and acquisition would have similar impacts to water quality as the Nonstructural Alternative that was analyzed. Therefore, refer to the discussion under Alternative 6 for the potential effects to sediment quality these potential mitigation measures would cause. The only structural mitigation measure being considered is a permanent pump station(s), although due to the cost of construction of a pump station(s) where one may be beneficial would make the implementation of this mitigation measure highly unlikely. If constructed, though, a pump station(s) would only operate during a storm event. The primary purpose of the pump station would be to minimize induced flooding on structures located outside the floodwalls where modeling has found induced flooding to be probable. If necessary, a permanent pump station(s) would collect rainfall and stormwater runoff that is not collected by the subsurface drainage system as it naturally flows to low-lying areas. The runoff would be pumped over/through the floodwall before water levels elevate to a level of inducing flooding to nearby structures. The construction of a pump station(s) would occur adjacent to a stream channel, but not within the stream channel. Therefore, the construction of a pump station(s) would not be expected to disturb or mobilize streambed sediments. Long-term, maintenance activities associated with a

pump station(s) typically include frequent inspections to assure normal functioning of pump station equipment and to identify potential problems early. Routine preventive maintenance would also occur to prevent unnecessary equipment wear and downtime. The above maintenance activities would have no impact on sediment quality. Long-term operation of a pump station(s) is automated and only occurs during a storm event. However, during a storm event, the operation of the pump station would collect rainfall and stormwater runoff and the runoff would be pumped over/through the floodwall. The stormwater runoff that is collected could contain contaminated sediments that would then be pumped into a stream/canal. Although the presence of a pump would likely increase the rate at which the stormwater runoff enters the stream/canal, the pump would not cause an increase in contaminant concentrations within the watershed. The stormwater runoff potentially containing contaminated sediments would have entered the watershed under the existing condition, but the rate at which it would have entered the watershed would have been slower than the rate at which it would enter the watershed with a pump station(s) in operation. In addition, where the water enters the stream/canal from the pump station(s), the velocity of the water entering the stream/canal could mobilize buried contaminants within the receiving stream/canal. BMPs would be implemented to minimize the velocity of the water from the pump station entering the stream/canal so that the mobilization of sediments would be less than significant. Therefore, the implementation of the above mitigation measures is expected to have no short-term adverse effect on sediment quality, but a less than significant long-term adverse effect on sediment quality.

Overall, construction, operation, maintenance, and potential mitigation measures associated with Alternative 1 is expected to have a less than significant adverse effect on sediment quality within the watershed.

Alternative 2B

Less than Significant Impact: The construction of Alternative 2B features, includes only one detention basin. However, floodwalls that would be constructed under Alternative 2B often have outlet structures associated with them. The detention basin included in Alternative 2B would have the same short-term and long-term impacts to sediment quality; therefore, refer to the discussion of those potential impacts under Alternative 1.

Alternative 2B includes the construction of more floodwalls than Alternative 1. The construction of floodwalls and road closure structures would avoid construction within a stream channel except for the segment of floodwall along the Manoa-Palolo Canal (part of the Ala Wai Canal floodwall) and a portion of floodwall along Makiki Stream. Construction of upland floodwalls would have no potential for disturbing potentially contaminated streambed sediments. For floodwall along the Manoa-Palolo Canal, it appears that it would be necessary to construct a temporary rock bench within the stream channel for equipment access during floodwall construction. This construction would require the use of BMPs to minimize impacts to the stream. Once constructed, the temporary bench would be removed, and the floodwalls would not impact the sediment conditions. The Koali Road and Ala Wai Canal floodwalls include outlet structures that would collect interior drainage behind a floodwall during a storm event and carry those waters to the receiving waterway on the downside of the floodwall. The outlet structures for the Ala Wai Canal floodwall are already existing stormwater drainage outlets that would be modified with a flap gate. The addition of the flap gate is not anticipated to disturb potentially contaminated streambed sediments. The Koali Road floodwall includes two outlet structures. Where these features connect to the receiving stream, construction activities could disturb streambed sediments. Although sediment-bound pollutants are known to occur throughout the watershed (particularly in the urbanized areas), none of the sediments that would be exposed by construction are expected to contain excessive levels of contamination. In addition, typically

less than 0.02 acre of streambed sediments would have the potential of being disturbed and potentially mobilized with the construction of the outlet structures.

Long-term, the operation and maintenance of the floodwalls is not expected to substantially increase contaminant concentrations within the watershed by remobilizing buried contaminants. Maintenance activities such as potential repairs and ensuring flap gates are working properly are not expected to require the disturbance of streambed sediments. The operation of the floodwalls, unlike the detention basin, would not allow streambed sediments that are mobilized due to increasing storm volumes during heavy rainfall to settle out of the water column. Instead, the floodwalls would likely increase stream volumes above existing conditions during heavy rainfall, as stormwater that is currently overflowing the channel banks of a stream would be contained within the floodwalls and shunted downstream. Due to the likely increase in stream volumes above existing conditions, increased mobilization of contaminated stream sediments could occur. The increase in mobilization of contaminated stream sediments is not expected to be significantly greater, though, since the stormwater from the upper watershed would be anticipated to slow down once it reaches the Kaimuki High School and Ala Wai Canal floodwalls which provide more surface area for the stormwater to spread out than a confined channel.

Alternative 2B also includes potential mitigation measures to address induced flooding. Refer to the effects analysis under Alternative 1 for the potential mitigation measures.

Overall, the construction, operation, maintenance, and potential mitigation measures associated with Alternative 2B are expected to have a less than significant adverse effect on sediment quality within the watershed.

Alternative 5.3

Less than Significant Impact: In general, the type of project features included in Alternative 5.3 would have similar construction, operation, maintenance, and mitigation requirements as Alternative 1 and Alternative 2B, although the extent of the work for the tentatively selected plan includes only one off-line detention basin and fewer floodwalls. As with Alternative 2B, some floodwall work may occur within the stream channels. Alternative 5.3 would also include potential mitigation measures for induced flooding. Due to the similarity in work required for Alternative 5.3, it is expected that the nature and degree of potential impacts to sediment quality are generally expected to be similar to those detailed above for Alternatives and 2B. Therefore, refer to the analysis under Alternatives 1 and 2B for Alternative 5.3 project effects. Overall, the construction, operation, maintenance, and potential mitigation measures associated with Alternative 5.3 are expected to have a less than significant adverse effect on sediment quality within the watershed.

In general, the type of project features included in Alternative 5.3 would have similar construction, operation, maintenance, and mitigation requirements as Alternatives 1 and 2B, such that the nature and degree of potential impacts to noise levels within the alternative action area are generally expected to be similar.

Alternative 6

No Impact: No short-term direct or indirect sediment quality impacts would occur as a result of implementation of Alternative 6 because land disturbance for this alternative would be limited to modification of existing buildings located upland. Implementation of Alternative 6 would require construction access to all structures to be treated, but this is expected to occur from existing roads. Similarly, localized maintenance such as repairs would be needed over time. Overall, no direct or indirect long-term adverse effects to sediment quality would occur as a result of this

alternative. Appropriate erosion and sediment control measures would be utilized during construction.

Environmental Commitments
No specific environmental commitments associated with impacts to sediment quality apply.

Best Management Practices
BMPs for sediment apply for any work within the channel, including inlet/outlet construction, temporary access for construction, or any features which would protrude into the canal or would potentially disturb the sediment:

- Sediment that must be excavated for installation of inlet and outlet structures would be disposed of upland in an appropriate facility. Disturbed areas would be stabilized with riprap and/or vegetation at the end of construction.
- A Section 401 Water Quality Certification would be obtained for any filling or dredging in the canal.
- If needed, soft sediment within the canal and along the area of bench construction or other disturbance would be dredged to remove sediment that would be easily disturbed. Dredged sediment would be dewatered, with the water likely being treated and/or discharged to the sanitary sewer system (under a discharge permit). Sediment is assumed to be of poor quality and would be treated/dried as needed and taken to a landfill.
- Silt (turbidity) curtains would be installed as needed, to minimize the release of turbidity downstream.
- A cofferdam would be installed as needed, to physically isolate the construction area. The area inside the cofferdam would be enclosed such that any sediment disturbed, or water impacts within the area would be isolated and not released downstream.
- Only clean stone, free of fines, would be used for constructing a temporary work bench within the canal. Stone would be placed using a crane (not dumped) to minimize the footprint and sediment disturbance. Stone would be removed at the end of construction. The channel bank would be restored with native vegetation.
- Sediment quality within the footprint of the work would be determined beforehand, so that appropriate provisions for construction and for sediment handling can be determined.
- The canal area would be surveyed for sensitive wildlife and habitat that requires protection. Environmental windows would be established as needed to prevent disturbance to nesting species, etc. Sensitive areas to avoid would be established.

3.3.9 Noise

Regulatory Setting
Relevant federal and state laws/regulations include:

- Noise Control Act
- HRS Chapter 342F (Noise Pollution)
- Chapter 11-46, Hawaii Administrative Rules

Existing Conditions
In general, ambient noise levels vary with land use throughout the study area. In the forested portions of the upper watershed, ambient noise levels are relatively low, with most sounds

associated with environmental factors such as wind, rain, and animals (particularly birds). In locations that interfere with low density development (i.e., residential areas and recreational facilities), sounds associated with human activity generally increase ambient noise levels. Within the urban areas of the study area, ambient noise levels range from relatively quiet residential neighborhoods to commercial and industrial areas, which typically generate higher levels of noise. Sources of noise include commercial and industrial operations, construction activities, intermittent aircraft flybys, and traffic, especially along the major arterial roads and freeways. Table 25 shows average decibel levels for common noises that may be encountered within the study area.

Table 25: Noise Levels for Common Sounds.

Noise	Average Decibels (dB)
Library	40
Large Office	50
Normal Conversation	60
Freeway Traffic	70
Handsaw	85a
Factory Machinery	100
Power Saw	110
Ambulance Siren	120
Jackhammer	130
Airplane Taking Off	140
Rocket Launch	180

[a] Sounds above 85 dB are considered harmful depending on how long and how often someone is exposed to them and whether hearing protection is being used.

Significance Criteria

Effects of noise and vibration would be considered significant if the proposed project would result in any of the following:

- Generation of a substantial temporary or permanent increase in ambient noise levels in the vicinity of the project in excess of standards established in the local noise ordinance, or applicable standards of other agencies.
- Cause long-term exposure of noise-sensitive receptor(s) to a substantial increase in noise levels over the ambient condition.
- Generation of excessive groundborne vibration or groundborne noise levels.

Environmental Consequences

Methodology: Construction of an alternative would require the use of heavy equipment that would temporarily increase noise and/or groundborne vibration levels at properties near the work sites. Construction equipment required for each project feature and construction site preparation was identified and the typical noise level (i.e., dBA) at 50 feet for that construction equipment was compiled using the U.S. Department of Transportation Construction Noise Handbook (USDOT, 2006). For each design feature and site preparation, the loudest piece of equipment was used to estimate construction noise impact on nearby sensitive receptors. It is important to note, that although the loudest piece of equipment was used in the analysis, construction activities would be intermittent. Therefore, actual noise levels could be somewhat lower than estimated values. Noise from construction activity generally attenuates (decreases) at a rate of 6.0 to 7.5 dBA per doubling of distance from the source. Any shielding effects that may result from local barriers such as topography, fences, vegetation, etc. are not incorporated, so the calculated noise levels represent a conservative or “worse case” scenario. The Federal Highway Administration (FHWA) has determined that an 80 dBA L_{eq} daytime construction noise

level at nearby residences would constitute a significant construction noise impact (FHWA, 2006).

Like noise, vibration attenuates with increasing distance, as a complex function of energy transfer into the ground and the soil conditions through which the vibration is transmitted. Calculations of vibration attenuation follow standard FTA methods (FTA, 2006). Short- and long-term vibration impacts would be considered significant if the project construction would expose sensitive receptors to or would generate vibration levels that exceed 0.2 in/sec peak particle velocity (PPV).

No Action

No Impact: Under the No Action Alternative, the flood risk management project would not be implemented, such that no increase in ambient noise levels would occur. Land uses under the future without-project condition are expected to be reasonably consistent with the existing land uses. Given that the types of noise and maximum permissible noise levels are linked to the various land use districts, the general range of ambient noise levels across the watershed is not expected to measurable change over the period of analysis.

Alternative 1

Less than Significant Impact with Environmental Commitments Incorporated: Construction of Alternative 1 would require the use of multiple pieces of construction equipment. The overall construction could take approximately 3 years. All construction activities would occur between 7:00 a.m. and 6:00 p.m. Monday through Friday and between 9:00 a.m. and 6:00 p.m. on Saturday to comply with the City of Honolulu noise ordinance established by the State of Hawaii Department of Health (Noise Section). In addition, an approved community noise permit is required for construction projects exceeding 78 dBA. The use of certain construction equipment, such as pile drivers, hydraulic hammers, jackhammers, etc., is limited to use Monday through Friday between 9:00 a.m. and 5:30 p.m.

Typical construction equipment noise emissions for each piece of construction equipment for site preparation and each project feature are found in Table 26 through Table 28.

Table 26: Construction Equipment Required for Site Preparation (i.e., Clearing & Grubbing) (FTA, 2006).

Equipment Type	Typical Sound Level at 50 ft (dBA)
Brush Chipper	85
Chain Saw	85
Crawler Dozer	85
Dump Truck	88
Excavator	85
Flatbed Truck	88
Front End Loader	80
Skid Steer	80
Water Truck	88

Table 27: Construction Equipment Required for Detention Basins, Including Inlet and Outlet Structures, and Associated Levees/Floodwalls (FTA, 2006).

Welder	73

The loudest piece of construction equipment for site preparation is 88 dBA at 50-ft. The loudest piece of construction equipment for detention basins (including inlet and outlet structures and associated levees/floodwalls) is 101 dBA at 50-ft. The loudest piece of construction equipment for floodwalls (including inlet structures) and road closure structures is 101 dBA at 50-ft. The FHWA has determined that an 80 dBA Leq daytime construction noise level at nearby residences would constitute a significant construction noise impact (FHWA, 2006). Therefore, certain features would require construction equipment that would exceed the FHWA daytime construction noise standard of 80 dBA Leq. In addition, some construction equipment used would also exceed 78 dBA, the threshold for which an approved community noise permit is required for construction projects by the City of Honolulu noise ordinance. This construction equipment is anticipated to surpass both above thresholds since residences in some places are within 20 feet of where construction work would be occurring. Since construction of certain features of the project would exceed the FHWA daytime construction noise standard, environmental commitments EC NV-1 through EC NV-6 (refer to environmental commitments section for additional details) would be implemented during construction to reduce potentially

significant noise impacts to nearby residences to less than significant. Therefore, with mitigation, Alternative 1 is expected to have a less than significant impact regarding the generation of a substantial temporary increase in ambient noise levels in the vicinity of the project in excess of standards established in the local noise ordinance, or applicable standards of other agencies.

Like noise, the FHWA has compiled vibration level data regarding vibration generating characteristics of several types of construction equipment that are shown in Table 29.

Table 29: Vibration Source Levels for General Construction Equipment (FHWA, 2006).

Equipment Type	Peak Particle Velocity at 25 feet (in/sec.)
Pile Driver	0.644
Vibratory Roller	0.21
Hoe Ram	0.089
Large Bulldozer	0.089
Caisson Drill	0.089
Loaded Trucks	0.076
Jackhammer	0.035
Small Bulldozer	0.003

As shown in Table 29 a pile driver would be the type of equipment anticipated to be used during construction activities that would create the highest vibration level of 0.644 in/sec PPV at 25-ft. Based on typical vibration propagation rates, the vibration level at some of the nearest residences to construction work (i.e., 20-ft) could actually exceed 0.644 in/sec and be as high as 0.900 in/sec (Caltrans, 2004). At this vibration level, potential structural damage could occur to extremely fragile historic buildings, ruins, ancient monuments; fragile buildings; historic and some old buildings; older residential structures; newer residential structures; and modern industrial/commercial buildings. The potential for structural damage to the least susceptible structure/structure condition (i.e., modern industrial/commercial buildings) would dissipate at approximately 30 feet from the vibration source. The potential for structural damage to the most susceptible structure/structure condition (i.e., extremely fragile historic buildings, ruins, ancient monuments) would dissipate at approximately 100 feet from the vibration source (Caltrans 2004).

In addition, at the 0.900 in/sec vibration level (i.e., 20 feet from the vibration source), the pile driver which is considered a continuous/frequent intermittent vibration source would rise to “severe” in terms of human annoyance level (Caltrans, 2004). At approximately 70 feet from the vibration source, the human annoyance level would drop to “strongly perceptible; at approximately 150 feet the human annoyance level would drop to “distinctly perceptible”; and lastly at approximately 300 feet the human annoyance level would drop to “barely perceptible” (Caltrans, 2004). Since construction of certain features would require construction equipment that at certain distances from the source would have the potential to cause structural damage and “severe” human annoyance, environmental commitments EC NV-1 through EC NV-6 (refer to environmental commitments section for additional details) would be implemented during construction to reduce potentially significant vibration impacts to nearby residences to less than significant. Therefore, with mitigation, Alternative 1 is expected to have a less than significant impact regarding the short-term generation of excessive groundborne vibration or groundborne noise levels.

Some locations are considered more sensitive to adverse effects from noise and groundborne vibrations. These locations are termed sensitive receptors and generally include schools, hospitals, senior living facilities, libraries, places of worship, cemeteries, parks/preserves, and residences. As discussed above, there are some residences within 20 feet of where construction activities would be occurring. In addition to residences, this analysis identified other sensitive receptors within 0.25 mile (i.e., 1,320 feet) of construction activities were identified. Any sensitive receptors located outside 0.25 mile would not be expected to have significant impacts as noise and vibrations from construction equipment would be expected to dissipate to ambient levels at this distance. Table 30 shows the sensitive receptors, excluding residences, and distance from the construction site for each project feature.

Table 30: List of Sensitive Receptors Within 0.25 Mile of Project Features.

Project Feature	Sensitive Receptor	Distance of Sensitive Receptor from Project Feature (miles)
Makiki District Park Detention Basin	1) Makiki District Park 2) Scottish Rite Cathedral 3) Christ United Methodist Church 4) St. Clement's School	≤ 0.10
Makiki District Park Detention Basin	1) Jodo Mission of Hawaii 2) Playmate Kindergarten, Day Care 3) Arcadia Retirement Residence 4) First Church of Christ Scientist 5) Hawaiian Mission Academy Ka Lama Iki 6) Punahou Square Park 7) Maryknoll High School 8) Shriners Children's Hospital 9) Honolulu Church of Christ 10) Cartwright Neighborhood Park	0.11-0.19
Makiki District Park Detention Basin	1) Lutheran Church of Honolulu 2) Kapiolani Medical Center for Women & Children	0.20-0.25
Kanaha Floodwall1) Christ United Methodist Church	≤ 0.10	
Kanaha Floodwall	1) Montessori Community School 2) Honolulu Church of Christ	0.11-0.19
Kanaha Floodwall	1) Robert Louis Stevenson Middle School	0.20-0.25

Project Feature	Sensitive Receptor	Distance of Sensitive Receptor from Project Feature (miles)
	2) President Theodore Roosevelt High School 3) Catholic Charities Hawaii 4) Lutheran Church of Honolulu 5) Arcadia Retirement Residence	
Manoa Valley District Park Detention Basin	1) Manoa Valley District Park 2) Manoa Community Garden	≤ 0.10
Manoa Valley District Park Detention Basin	1) Manoa Elementary School 2) Manoa Elderly Housing 3) St. Pius X Parish	0.11-0.19
Manoa Valley District Park Detention Basin	1) Manoa Senior Living	0.20-0.25
Woodlawn Drive Floodwall	1) St. Pius X Parish 2) Noelani Elementary School 3) Youth with a Mission	0.11-0.19
Koali Road Floodwall	1) Kanewai Community Park	≤ 0.10
Koali Road Floodwall	1) Hale Aloha Ilima	0.11-0.19
Koali Road Floodwall	1) Chaminade University of Hawaii	0.20-0.25
Kaimuki High School Floodwall	1) Kaimuki High School 2) Ala Wai Golf Course	≤ 0.10
Kaimuki High School Floodwall	1) Moiliili Japanese Cemetery 2) Iolani Lower School 3) St. Alban's Chapel 4) Lukepane Community Garden	0.11-0.19
Kaimuki High School Floodwall	1) Prince Jonah Kuhio Elementary School	0.20-0.25
Ala Wai Golf Course Berm	1) Ala Wai Golf Course 2) Kaimuki High School 3) Lukepane Community Garden	≤ 0.10
Ala Wai Golf Course Berm	1) Iolani School 2) President Thomas Jefferson Elementary 3) Hawaii School for the Deaf and the Blind 4) St. Alban's Chapel	0.11-0.19
Ala Wai Golf Course Berm	1) Paki Community Park	0.20-0.25

The loudest piece of construction equipment for site preparation is 88 dBA at 50-ft. The loudest piece of construction equipment for detention basins (including inlet and outlet structures and associated levees/floodwalls) is 101 dBA at 50-ft. The loudest piece of construction equipment

for floodwalls (including inlet structures) and road closure structures is 101 dBA at 50-ft. For site preparation, the loudest piece of construction equipment (i.e., dump truck at 88 dBA) would dissipate below 80 dBA Leq threshold for sensitive receptors located approximately 100-150 feet away from the noise source. In addition, the loudest piece of construction equipment for site preparation would dissipate below 78 dBA Leq threshold for sensitive receptors located approximately 150 feet from the noise source. The loudest piece of construction equipment for detention basin and floodwall construction is a pile driver (i.e., 101 dBA) for which the noise level would dissipate below the 80 dBA Leq threshold for sensitive receptors located approximately 200 to 250 feet from the noise source. In addition, the loudest piece of construction equipment would dissipate below the 78 dBA Leq threshold for sensitive receptors located approximately 250 feet from the noise source. Therefore, sensitive receptors located approximately 0.11 to 0.25 miles from the construction sites are not expected to have temporary increases in ambient noise levels due to construction of Alternative 1. Similarly, except for the construction sites themselves, which are often sensitive receptor locations (i.e., Kaimuki High School, Manoa Valley District Park, etc.), sensitive receptors located less than 0.10 mile from the construction sites are not expected to have temporary increases in ambient noise levels due to construction as most of these sensitive receptors are located at least 500 feet from the noise sources. However, as stated above, this doesn't consider the residences which are located within at least 20 feet of some construction sites. Therefore, as stated above, since the noise level at residences would exceed the FHWA daytime construction noise standard of 80 dBA Leq and the 78 dBA threshold set by the City of Honolulu noise ordinance; environmental commitments EC NV-1 through EC NV-6 (refer to environmental commitments section for additional details) would be implemented during construction to reduce potentially significant noise impacts to nearby residences and other sensitive receptors to less than significant. Therefore, with mitigation, Alternative 1 is expected to have a less than significant impact with regard to causing short-term exposure of noise-sensitive receptors to a substantial increase in noise levels over the ambient condition.

Long-term, the operation and maintenance of the project is not expected to generate consistent noise levels that would exceed current condition ambient noise levels. The operation of the project is passive in that no generators, pump stations, etc. that would generate noise on an intermittent basis would be needed. Maintenance activities would generally require the use of passenger vehicles to check floodwalls, detention basins, and road closure structures. If repairs or debris clearing is needed, then equipment such as that shown in Table 28 would be expected to be used. Therefore, the long-term operation and maintenance of Alternative 1 is expected to have a less than significant impact regarding the generation of a substantial permanent increase in ambient noise levels in the vicinity of the project in excess of standards established in the local noise ordinance, or applicable standards of other agencies.

Long-term, the operation and maintenance of the project is not expected to generate consistent vibration levels that would potentially cause structural damage or reach a human annoyance level for vibration. The operation of the project is passive in that no equipment would be required to operate any of the flood risk management features. Therefore, there would be no equipment to generate ground vibrations consistently. Maintenance activities would generally require the use of passenger vehicles to check floodwalls, detention basins, and road closure structures. If repairs or debris clearing is needed, then equipment such as that shown in Table would be expected to be used. The crawler dozer could have a PPV like that of a small bulldozer as listed in Table 29. At a distance of 20 feet, the crawler dozer would have a PPV of 0.004 in/sec which wouldn't even rise to the level of potentially causing structural damage to extremely fragile historic buildings, ruins, or ancient monuments. Similarly, a PPV of 0.004 in/sec would be under the maximum vibration level for a continuous/frequent intermittent source

to be “barely perceptible” in terms of human annoyance level. Therefore, the long-term operation and maintenance of Alternative 1 is expected to have a less than significant impact regarding the long-term generation of excessive groundborne vibration or groundborne noise levels.

Alternative 1 would also include potential mitigation measures to address induced flooding. Nonstructural mitigation measures under consideration include dry/wet floodproofing, elevation, and acquisition. The potential effects of the nonstructural mitigation measures under consideration would have similar effects to those discussed under Alternative 6; therefore, refer to the effects analysis for Alternative 6 regarding these mitigation measures. The only structural mitigation measure for induced flooding under consideration is a pump station(s). The precise location of the pump station(s) and size is unknown at this time. It is also highly unlikely that a pump station(s) will be included as a mitigation measure for induced flooding. However, if a pump station(s) remains as a mitigation measure under consideration the following provides a broad overview of the effects on noise. During construction, equipment required would be similar to that listed in Table 27. Although the location and distance from sensitive receptors for a pump station(s) is unknown at this time, due to the urban nature of the area it is a conservative assumption that construction equipment could be within 0.25 mile (i.e., 1,320 feet) of residences and other sensitive receptors—even within 20 feet of residences and other sensitive receptors. With the implementation of environmental commitments EC NV-1 through EC NV-6 (refer to environmental commitments section for additional details) during construction activities, potentially significant adverse noise effects to nearby residences and other sensitive receptors would be minimized to less than significant adverse effects. Regarding short-term vibrations during construction, the construction activities are not expected to require a pile driver. Therefore, the piece of equipment with the highest potential for generating ground borne vibration is likely a caisson drill with a PPV of 0.089 at 25 feet. Therefore, if residences or other sensitive receptors are located within 20 feet of the pump station, as a conservative assumption, the PPV would be 0.124 at 25 feet. At this PPV for a continuous/frequent intermittent source, extremely fragile historic buildings, ruins, ancient monuments, and fragile buildings could potentially be at risk for structural damage during construction. Regarding sensitive receptors, 0.124 PPV at 20 feet would be “strongly perceptible” in terms of human annoyance level. Therefore, ground-borne vibrations from construction activities could cause a significant adverse impact, but with the implementation of EC NV-1 through EC NV-6 (refer to environmental commitments section for additional details) during construction activities, these potentially significant adverse effects would be reduced to less than significant adverse effects.

Long-term, operation and maintenance of the pump station(s) could generate noise and ground-borne vibration levels above ambient levels when the pump station(s) is operating. During operation, the pump motor would be a temporary source of noise and vibration which may negatively impact nearby residences and sensitive receptors. To minimize potential noise and vibration effects the following measures would be considered during the design of the pump station(s) if found to be necessary as a mitigation measure: 1) use of submersible pumps; 2) use of electrically driven motors where submersible pumps are not practical; 3) provision of appropriate mufflers if engines are used; and 4) use of concrete or masonry for the building of the pump house. Sound insultation of the pump house walls may be an option; however, the effectiveness of such a measure may be reduced by necessary station ventilation. Maintenance of a pump station could potentially be frequent, but equipment used would be primarily hand tools to make sure parts of the pump station remain in good working condition and replacement of pump parts when necessary. Therefore, the long-term operation and maintenance of a pump station(s) would have an adverse effect on nearby residences and sensitive receptors; however, due to the operation of the pump being only during a storm event and the design of the pump

station including potential noise mitigation measures as described above, a pump station(s) would be expected to have a less than significant adverse effect on noise and vibration levels.

Overall, Alternative 1 would have a short-term significant adverse effect and a long-term less than significant adverse effect on noise and vibration levels in the watershed. The short-term significant adverse effect would be reduced to less than significant with the implementation of mitigation measures EC NV-1 through EC NV-6 (refer to environmental commitments section for additional details).

Alternative 2B

Less than Significant Impact with Environmental Commitments Incorporated: In general, the type of project features included in Alternative 2B would have similar construction, operation, maintenance, and mitigation requirements as Alternative 1, such that the nature and degree of potential impacts to noise levels within the alternative action area are generally expected to be similar. It is important to note that Alternative 2B includes a floodwall around the Ala Wai Canal and doesn't include the Manoa Valley District Park Detention Basin. In addition, Alternative 2B would take approximately 3.5 years for construction. Therefore, refer to Table 31 for the sensitive receptors located within 0.25 mile of construction sites specific to Alternative 2B.

Overall, Alternative 2B would have a short-term significant adverse effect and a long-term less than significant adverse effect on noise and vibration levels in the watershed. The short-term significant adverse effect would be reduced to less than significant with the implementation of mitigation measures EC NV-1 through EC NV-6 (refer to environmental commitments section for additional details).

Alternative 5.3

Less than Significant Impact with Environmental Commitments Incorporated: In general, the type of project features included in Alternative 5.3 would have similar construction, operation, maintenance, and mitigation requirements as Alternative 1 and Alternative 2B, such that the nature and degree of potential impacts to noise levels within the alternative action area are generally expected to be similar. It is important to note that Alternative 5.3 includes a floodwall around the Ala Wai Canal and the Ala Wai Golf Course detention basin. In addition, the construction of Alternative 5.3 would take approximately 4 years. Refer to Table 32 for the sensitive receptors located within 0.25 mile of construction sites specific to Alternative 5.3.

Overall, Alternative 5.3 would have a short-term significant adverse effect and a long-term less than significant adverse effect on noise and vibration levels in the watershed. The short-term significant adverse effect would be reduced to less than significant with the implementation of mitigation measures EC NV-1 through EC NV-6 (refer to environmental commitments section for additional details).

Table 32: List of Sensitive Receptors Within 0.25 Mile of Project Features.

Project Feature	Sensitive Receptor	Distance of Sensitive Receptor from Project Feature (miles)

Ala Wai Canal Floodwall	1) Paki Community Park 2) Hawaii School for the Deaf and Blind 3) King William C. Lunalio Elementary School	0.20-0.25

Alternative 6

Less than Significant Impact: The implementation of Alternative 6 would have no long-term direct or indirect adverse noise effects. However, minor short-term adverse noise effects are expected to result from implementation of Alternative 6, because construction for this alternative would take place in populated areas throughout Honolulu and would include modification of existing buildings. These impacts will be similar to that of the structural alternatives, except that less equipment and a shorter time at each location will be needed to raise a structure. Noise due to construction could be ten dBA higher than ambient noise up to 400 feet away from the construction site. Non-physical actions will not affect noise levels. Overall, this Alternative will have a short-term, minor adverse effects, during construction only. The duration of time to complete all of the work for this alternative is not known at this time. As an example of potential construction time required, if five structures were floodproofed/elevated per week it would take approximately 7.5 years to complete. However, just as for the structural alternatives, noise levels would be subject to local noise ordinance requirements. Construction would be expected to occur only during daylight hours and not occur at night, early mornings, or on Sundays.

Environmental Commitments

The following specific environmental commitments would be implemented by the contractor during construction activities to further reduce any potential noise effects.

EC NV-1: Obtain a community noise permit from the City of Honolulu.

EC NV-2: Appropriate level of sound attenuation would be used during construction to meet local ordinances. Potential sound attenuation measures that could be considered include, but are not limited to, temporary sound barriers between the sources of construction noise and noise-sensitive receptors, as appropriate.

EC NV-3: Residents and businesses near the construction sites would be provided with advance notice of project activities, schedule, anticipated traffic, and potential noise issues. The advance notice would describe the potential noise disruption and the steps that would be taken to minimize the noise.

EC NV-4: Haul trucks operating near sensitive receptor sites would be spaced apart to avoid noise effects from simultaneous operation.

EC NV-5: Engineer brake (jake brake) use within city limits would be prohibited. Many noise complaints arise from heavy truck use of engine brakes to slow the truck down. Use of this type of braking can be avoided by proper speed control.

EC NV-6: The contractor would properly maintain and tune engines of all equipment and maintain properly functioning mufflers on all internal combustion engines to minimize noise levels.

Best Management Practices

No BMPS associated with impacts due to noise apply.

3.4 Natural Environment

Regulatory Setting

Regulations and policies that protect the natural environment include the following:

- Endangered Species Act (ESA)
- Migratory Bird Treaty Act
- Magnuson-Stevens Fishery Conservation and Management Act
- Marine Mammal Protection Act
- Clean Water Act, Section 404
- HRS Chapter 195D (Conservation of Aquatic Life, Wildlife, and Land Plants)
- HRS Chapter 174C (State Water Code)
- EO 11990 – Protection of Wetlands
- EO 13112 – Invasive Species

In addition to the above regulations, the Fish and Wildlife Coordination Act (FWCA) required federal agencies to coordinate with the USFWS and State wildlife agencies during project planning to provide for adequate consideration of wildlife resource conservation, including minimization of adverse effects and compensation for wildlife resource losses. Coordination with USFWS and DLNR (including both DOFAW and DAR) has been conducted throughout the planning process. Input received to date has been integrated into the planning process, as summarized in this report: no high-risk issues or concerns have been raised to date. Compliance with ESA Section 7 is discussed in Section 3.4.4. Supporting documentation is contained in Appendix K; this content is also being used for compliance with HRS Chapter 195D.

Existing Conditions

3.4.1 Plant Communities

In general, plant communities within the lower reaches of Manoa and Palolo streams and all of Makiki stream are completely dominated by non-native and invasive plant species, with little to no remaining native plant species cover. To describe the plant communities within the study area, the Ala Wai Watershed can be divided into two separate land uses: Forest Reserve and Urban (Figure 21).

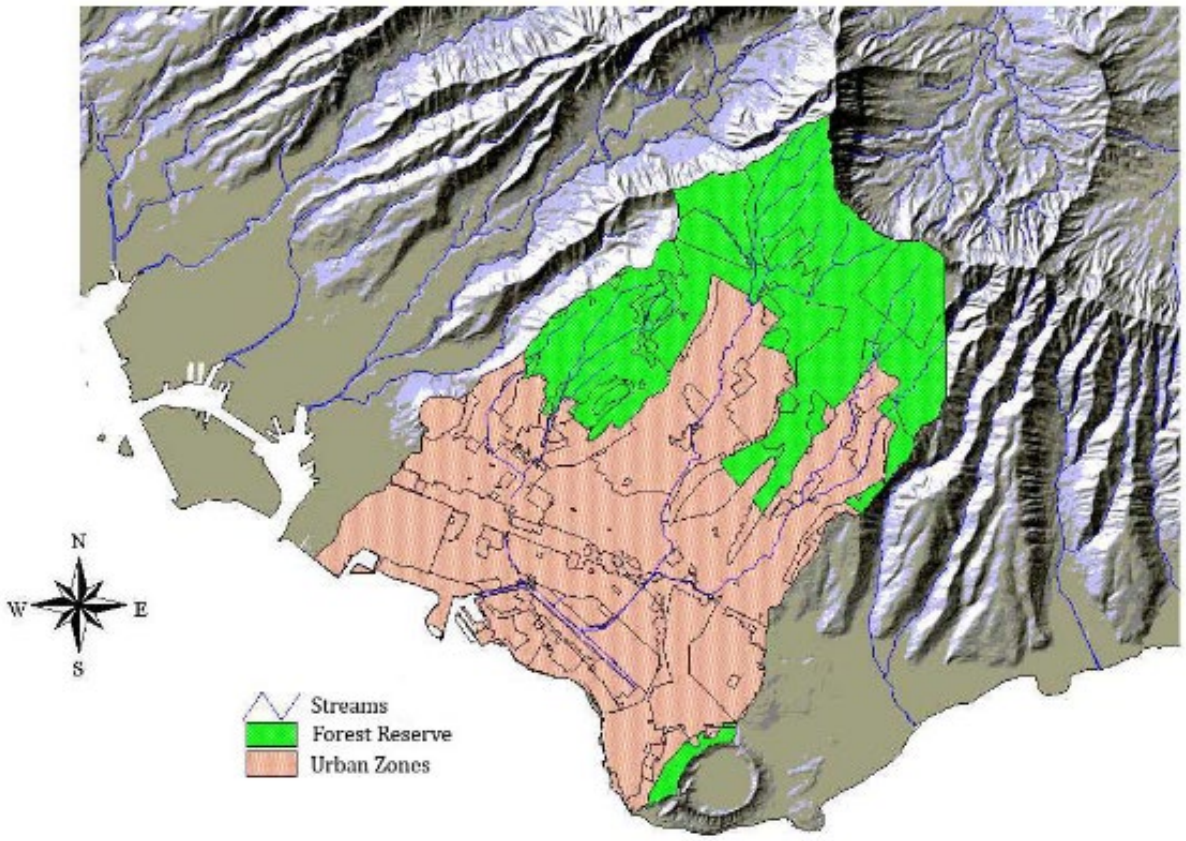

Figure 21: Ala Wai Watershed Study Area Depicting Forest Reserve Land Use Versus Urban Land Use (Oceanit, 2004)

As seen in Figure 21, the upper reaches of the study area above the urban land use areas are part of the Honolulu Watershed Forest Reserve. Plant communities within the steeper areas of the Honolulu Watershed Forest Reserve (i.e., slopes at and below the Koolau ridgeline to roughly about the 1500-feet contour) are relatively undisturbed and mostly dominated by native vegetation (AECOS, 2010). The habitat has been classified as mixed fern shrubland comprised of native plant species such as *'ōhi'a* (*Metrosideros polymorpha*), *uluhe* fern (*Dicranopterus linearis*), *'ama'u* ferns (*Sadleria cyatheoides* and *S. pallida*), *uluhe lau nui* (*Diplopterygium pinnatum*), *loulu hiwa* palm (*Pritchardia martii*), *pūkiawe* (*Leptecophylla tameiameia*), *'ōhelo* (*Vaccinum calycinum*), and *'ape'ape* (*Gunnera petaloïdea*). Below the mixed fern shrubland plant community is wet forest which grades into mesic forest at yet lower elevations just above the urban areas. Introduced species predominate these plant communities, particularly trees and shrubs such as Moluccan albizia (*Falcateria moluccana*), eucalyptus (*Eucalyptus globulus* and *E. robusta*), Chinese banyan (*Ficus macrocarpa*), guava (*Psidium cattleianum* and *P. guajava*), Christmas berry (*Schinus terebinthefolius*), mango (*Mangifera indica*), and shoebutton ardisia (*Ardisia elliptica*). Within the urban areas, the vegetation community is comprised primarily of planted and tended ornamental species. Regarding the riparian vegetation community there is very little within the urban areas due to flood risk management features and residences abutting the stream channels. The lower, concrete lined Palolo Stream completely lacks riparian vegetation in most places. Much of the middles reach of Makiki Stream is contained within an underground box culvert and therefore also lacks riparian plant species. The tributary streams above the urban areas are sometimes shaded by large, non-native plant species such as Chinese banyan (*Ficus macrocarpa*), mango (*Mangifera indica*), and gum

(*Eucalyptus sp.*). Mangrove trees (*Rhizophora mangal*) dominate some areas in the lower estuarine reaches of the Manoa-Palolo Drainage Canal and Ala Wai Canal, although concrete walls and concrete rubble masonry (CRM) walls constructed as banks have eliminated much of the riparian vegetation community (AECOS, 2010). Overall, approximately 238 plant species have been identified within the study area with the majority being non-native, naturalized plants. Only 11 are indigenous (native to the Hawaiian Islands and other Pacific Islands), one is a possible endemic (uniquely native to the Hawaiian Islands), and eight are early Polynesian introductions to the islands.

3.4.2 Wildlife Communities

The wildlife community within the study area includes native species such as the *Oahu amakihi* (*Hemignathus chloris*), Apapane (*Himatione sanguinea*), and the Hawaiian Hoary Bat (*Lasiurus cinereus semotus*). Many non-native and invasive species are commonly observed within all areas of the watershed and include species such as Indian Mongoose (*Herpestes a. aruopunctatus*), feral cats (*Felis catus*), Black Rat (*Rattus rattus*), Norway Rat (*Rattus norvegicus*), and the Polynesian Rat (*Rattus exulans*). Feral pigs (*Sus scrofa*) are another common non-native and invasive species that has been introduced to the Hawaiian Islands and may be found in the study area. Feral pig can cause extensive damage to the understory of forest and riparian habitat by uprooting plants and small trees, by contributing to soil erosion with their massive consumption of understory vegetation, and cause soil compaction (Stone and Scott, 1985; Tep and Gaines, 2003). The impact by feral pigs on forests and understory vegetation can contribute to increased flooding and erosion within a watershed.

According to the Cornell Lab of Ornithology's eBird website, approximately 90 bird species have been observed across eight birding hotspots within the study area (i.e., Lyon Arboretum, Mānoa Cliffs Trail, Waahila Ridge State Recreation Area, Ala Moana Park and State Recreation Area, Fort DeRussy Beach Park, Kuhio Beach Park, Honolulu Zoo, and Kapiolani Park) (Cornell Lab of Ornithology, 2022). Common species with the greatest number of observations in the study area (i.e., over 100 observations) are Cattle Egret (*Bubulcus ibis*), Common Myna (*Acridotheres tristis*), Common Waxbill (*Estrilda astrild*), House Finch (*Haemorhous mexicanus*), House Sparrow (*Passer domesticus*), Java Sparrow (*Lonchura oryzivora*), Pacific Golden-Plover (*Pluvialis fulva*), Red-crested Cardinal (*Paroaria coronate*), Rock Pigeon (*Columbia livia*), Rose-ringed Parakeet (*Psittacula krameria)*, Spotted Dove (*Spilopelia chinensis*), Wedge-Tailed Shearwater (*Puffinus pacificus*), White Tern (*Gygis alba*), Yellow-fronted Canary (*Serinus mozambicus*), and Zebra Dove (*Geopelia striata*) (Cornell Lab of Ornithology, 2022). Indigenous seabirds that may be observed flying over the watershed include the Great Frigatebird (*Fregata minor*), White-tailed Tropicbird (*Phaethon lepturus*), White Tern (*Gygis alba*), and the Brown Booby (*Sula leucogaster*) (KMWP, 2002). Migratory shorebird species with the potential to occur within the study area include the Pacific Golden-Plover, Wandering Tattler (*Tringa incana*), and the Ruddy Turnstone (*Arenaria interpres*). Non-native bird species that have introduced disease, displaced native bird species, and have been observed within the study area include the Japanese Bush Warbler (*Horornis diphone*), Warbling White-Eye (*Zosterops japonicus*), Red-vented Bulbul (*Pycnonotus cafer*), and Zebra Dove (*Geopelia striata*) (KMWP, 2002).

3.4.3 Aquatic Communities

Like vegetation communities within the study area, aquatic communities within the Ala Wai Watershed are primarily dominated by non-native and invasive species. Native freshwater fish in Hawaii are limited to five gobioid species (*'o'opu*), including one indigenous *'o'opu nākea* (*Awaous guamensis*) and three endemic *o'opu alamo'o* (*Lentipes concolor*), *'o'opu nōpili* (*Sicyopterus stimpsoni*), and *'o'opu naniha* (*Stenogobius hawaiiensis*) gobies, and one endemic eleotrid *'o'opu akupa* (*Eleotris sandwicensis*) (Kinzie, 1990). The native stream aquatic

community also includes several shrimp species of *'opae kala'ole* and *'opae 'oeha'a* (*Atyoida sp.* and *Macrobrachium sp.*), and mollusk species *Neritina126ompletenea* and *Neritina granosa*. All these native species have been recently documented in the Ala Wai Watershed except for *o'opu alamo'o* and *hihiwai* (Parham et al., 2015; Parham et al., 2008; Kido, 2008). However, observations of native aquatic species within the watershed are limited due to the abundance of introduced fish and invertebrate species such as smallmouth bass (*Micropterus dolomieu)*, tilapia (*Sarotherodon melanotheron*), Chinese catfish (*Clarias fuscus*), Tahitian prawn (*Macrobrachium lar*), and leeches (*Myzobdella lugubris*) which outcompete native species for forage, shelter, and reproductive habitat. The following paragraphs provide brief overviews of the aquatic communities specific to Palolo Stream, Manoa Stream, Makiki Stream, Ala Wai Canal and Manoa-Palolo Drainage Canal, and Waikiki Beach.

The Palolo Stream aquatic community is dominated by the bristle-mouth armored catfish (*Ancistrus* cf. *temminckii.*) and the suckermouth armored catfish (*Hypostomus* cf. *watwata group*), which was found to be abundant at the Manoa-Palolo stream confluence (AECOS, 2010). Also found within large numbers, especially in the upper Palolo Stream reaches, is the non-native atyid shrimp (i.e., Taiwan blue shrimp or *Neocaridina126ompletenesa sinensis*). No native Hawaiian aquatic fauna was noted in the valley of the lower Palolo valley stream reaches. Regarding algae, the overall taxonomic diversity is relatively low (i.e., only seven species were collected), although algal densities were high. Conversely, aquatic invertebrate (e.g., small aquatic insects, crustaceans, and mollusks) diversity was found to be low.

Within Manoa Stream, the aquatic community is dominated by non-native top-minnows, tilapia, and armored catfishes. In somewhat lesser abundance are guppies (*Poecilia reticulata*), swordtails (*Xiphophorus helleri*), and mosquitofish (*Gambusia affinis*). Native fish species found within Manoa Stream include *'o'opu nōpili*, *'o'opu nākea*, and *'o'opu 'akupa*. Also present in Manoa Stream is the endemic *hapawai* (a snail, *Neritina126ompletenea*). Non-native aquatic invertebrates prevalent in Manoa Stream include the Asiatic clam (*Corbicula fluminea*), *Neocaridina126ompletenesa* (a snail), and *Melanoides126ompletenesa* (a worm).

The Makiki Stream aquatic community includes native species such as mullet (*Mugil cephalus*), barracuda (*Sphyraena barracuda*), and native gobies (i.e., *Awaous sp.* and *Stenogobius sp.*). The native invertebrate *Macrobranchium grandimanus* (a crustacean) is also found in Makiki Stream. The most abundant non-native species within Makiki Stream is tilapia. For additional details on the freshwater aquatic environment refer to the 2017 FEIS and its associated Final Fish and Wildlife Coordination Act Report.

The Ala Wai Canal and the Manoa-Palolo Drainage Canal are considered entirely estuarine. Tidal influence for the Manoa-Palolo Drainage Canal extends from the canal's intersection with the Ala Wai Canal upstream about 300 feet, roughly midway along Kaimuki High School. Mangroves dominate in the lower estuary on both banks. A relatively large percentage of native fish species have been observed in the Ala Wai Canal and Manoa-Palolo Drainage Canal including barracuda, mullet, and *aholehole* (*Kuhlia sandvicensis*). There is also an abundance of Tilapia and Armored catfishes that likely compete with the two native goby species.

Fish species caught within the Ala Wai Boat Harbor include Great Barracuda (*Sphyraena barracuda*), Wedge-tail Triggerfish (*Rhinecanthus rectangulus*), Crevalle Jack (*Caranx hippos*), Hawaiian Ladyfish (*Elops hawaiensis*), Doublespotted Queenfish (*Scomberoides lysan*), Skipjack Tuna (*Katsuwonus pelamis*), West Atlantic Bonefish (*Abula vulpes*), Giant Trevally (*Caranx ignobilis*), Southern Puffer (*Sphoeroides nephelus*), Smallmouth Bass, Pacific Barracuda (*Sphryaena argentea*), Bluefin Trevally (*Caranx melampygus*), Eyestripe Surgeonfish

(*Acanthurus dussumieri*), Blackchin Tilapia (*Sarotherodon melanotheron*), Stocky Hawkfish (*Cirrhitus pinnulatus*), Manybar Goatfish (*Parupeneus multifasciatus*), Blue Tilapia (*Oreochromis aureus*), Wahoo (*Acanthocybium solandri*), Black Seabass (*Centropristis striata*), Common Dolphinfish (*Coryphaena hippurus*), Orange Goatfish (*Mulloidichthys flavolineatus*), Red Grouper (*Epinephelus morio*), Inshore Lizardfish (*Synodus foetens*), and Leopard Moray Eel (*Enchelycore pardalis*).

Marine aquatic habitat within 1,640 feet of the mouth of the Ala Wai Harbor was surveyed by the USFWS (USFWS, 2023). The surveyed area primarily included Shoreline Intertidal, Harbor, Reef Flat, and Reef Crest zones seaward of Ala Wai Harbor and Waikiki Beach seaward of Ft. DeRussy. The observed area included modified intertidal beach and a mix of natural reef flat and reef flat areas that have been modified to provide access to small dug out harbors at Waikiki Beach. Visual surveys indicated that the survey area was relatively typical of historically modified urban beaches, harbors, and coral reef environment. Coral abundance was generally low (< 10% cover) throughout. Small (< 19.7 inches) to large (19.7 – 78.7 inches) lobate corals were most common on the reef flats, followed by small medium-branching, encrusting, and microatoll growth forms. The most common coral species observed included *Porites rus*, *P. compressa*, *P. lobata*, and potentially other species of massive Porites, branching *Pocillopora spp.*, and encrusting *Montiposa spp*. Zoanthids were sparsely disturbed on reed flats. Frondose algae, CCA, and turf algae were common but not dominant throughout the surveyed area. Invasive algal species observed included *Gracilaria127ompletenea*, *Acanthophera spicifera*, and *Avrainvillea sp*. Filamentous algae or cyanobacteria were present, particularly seaward of Waikiki beaches but did not dominate the habitat. Spiny urchins were common, and rock boring urchins were dominant throughout the surveyed area. Sea cucumbers were observed throughout the surveyed area and occurred in clusters in certain reef flat areas. Molluscs were observed sparsely throughout the surveys. Sponges were observed in clusters, primarily seaward of Ala Wai Harbor. Tunicates were observed primarily in areas directly adjacent to channels and harbor areas. Green sea turtles were observed swimming at 16 locations within the surveyed area. No marine mammals were observed (USFWS, 2023). For additional details on the marine aquatic habitat refer to the Draft Fish and Wildlife Coordination Act Report (USFWS, 2023) found in Appendix K.

3.4.4 Federal Listed Species and Species of Special Concern

Several of the wildlife species within the study area are listed as threatened or endangered under the federal Endangered Species Act (ESA) and/or State law (HRS Chapter 195D [Conservation of Aquatic Life, Wildlife, and Land Plants]). Regarding federal listed species with the potential to occur within the study area, official species lists were obtained from the USFWS iPaC website (Project Codes: 2023-0048409; 2023-0048319; 2023-0048348; 2023-0048352; 2023-0048400). The following twenty-six federally listed species have the potential of occurring within the vicinity of the study area (Table 33):

Table 33: Federally Listed Species with the Potential of Occurring within the Study Area.

Species	Federal Status	Potential to Occur
Mammals		
Hawaiian Hoary Bat (*Lasiurus cinereus semotus*)	Endangered	**Moderately Likely to Occur**; Minimal low-quality habitat present within project footprint.
Hawaiian Monk Seal (*Monachus schauinslandi*)	Endangered	**Moderately Likely to Occur;** Minimal low-quality foraging

Species	Federal Status	Potential to Occur
		habitat present adjacent to the project footprint.
Birds		
Band-rumped Storm-petrel – Hawaii Distinct Population Segment (DPS) (*Oceanodroma castro*)	Endangered	**Moderately Likely to Occur**; Nesting habitat is not present within action area; Potential for foraging and flying over action area to Pacific Ocean.
Hawaii Akepa (*Loxops coccineus*)	Endangered	**Not Likely to Occur**; Suitable habitat is not present within action area.
Hawaiian Duck (*Anas wyvilliana*)	Endangered	**Moderately Likely to Occur**; Minimal low-quality habitat present within action area.
Hawaiian Common Gallinule (*Gallinula galeata sandvicensis*)	Endangered	**Moderately Likely to Occur**; Minimal low-quality habitat present within action area.
Hawaiian Coot (*Fulica americana alai*)	Endangered	**Moderately Likely to Occur**; Minimal low-quality habitat present within action area.
Hawaiian Petrel (*Pterodroma sandwichensis*)	Endangered	**Moderately Likely to Occur**; Nesting habitat is not present within project footprint; Potential for flying over action area to foraging grounds (Pacific Ocean).
Hawaiian Stilt (*Himantopus mexicanus knudseni*)	Endangered	**Likely to Occur**; Minimal low-quality habitat present within action area.
Newell's Townsend's Shearwater (*Puffinus auricularis newell*i)	Threatened	**Moderately Likely to Occur**; Nesting habitat is not present within project footprint; Potential for foraging and flying over action area to Pacific Ocean.
Short-tailed Albatross (Phoebastria albatrus)	Endangered	**Not Likely to Occur**; Suitable habitat is not present within action area.
Reptiles		
Green Sea Turtle (Chelonia mydas)	Threatened	**Likely to Occur;** Suitable foraging habitat present within action area.
Hawksbill Sea Turtle	Endangered	**Moderately Likely to Occur**; Suitable foraging habitat present within action area.
Flowering Plants		
ʻaiea (*Nothocestrum latifolium*)	Endangered	**Not Likely to Occur**; Suitable habitat is not present within action area.

Species	Federal Status	Potential to Occur
‘akoko (*Euphorbia celastroides var. kaenana*)	Endangered	**Not Likely to Occur**; Suitable habitat is not present within action area.
‘ena’ena (*Pseudognaphalium sandwicensium var. molokaiense*)	Endangered	**Not Likely to Occur**; Suitable habitat is not present within action area.
Carter’s Panicgrass (Panicum fauriei var. carteri)	Endangered	**Not Likely to Occur**; Suitable habitat is not present within action area.
Ewa Plains ‘akoko (Euphorbia skottsbergii var. skottsbergii)		**Not Likely to Occur**; Suitable habitat is not present within action area.
Ihi (Portulaca villosa)	Endangered	**Not Likely to Occur**; Suitable habitat is not present within action area.
Kamanomano (*Cenchrus agrimonioides*)	Endangered	**Not Likely to Occur**; Suitable habitat is not present within action area.
Lobelia monostachya	Endangered	**Not Likely to Occur**; Suitable habitat is not present within action area.
Polyscias lydgatei	Endangered	**Not Likely to Occur**; Suitable habitat is not present within action area.
Popolo (Solanum nelsonii)	Endangered	**Not Likely to Occur**; Suitable habitat is not present within action area.
Pu’uka’a	Endangered	**Not Likely to Occur**; Suitable habitat is not present within action area.
Ohai (Sesbania tomentosa)	Endangered	**Not Likely to Occur**; Suitable habitat is not present within action area.
Vigna o-wahuensis	Endangered	**Not Likely to Occur**; Suitable habitat is not present within action area.
Ferns and Allies		
Ihi’ihi	Endangered	**Not Likely to Occur**; Suitable habitat is not present within action area.
Microlepia129ompletea var. mauiensis	Endangered	**Not Likely to Occur**; Suitable habitat is not present within action area.

Critical habitat has been designated within the action area for the Hawaiian monk seal. In addition, critical habitat has been proposed within the action area for the green sea turtle.

Due to the action area being generally comprised of either low density vegetated non-native riparian/forest habitat (such as that associated with floodwalls along the middle watershed), turf

grass (such as that associated with the detention basins), or developed areas (such as that associated with the floodwalls along the lower watershed), federally endangered or threatened plant species that have the potential to occur in the action area are not expected to occur due to the lack of suitable habitat. Because of the lack of suitable habitat present for these species within the action area, a project is expected to have no effect on these species, or their designated critical habitat and they are not discussed further.

Hawaiian Hoary Bat (*Lasiurus cinereus semotus*)

The Hawaiian hoary bat is a listed federally endangered species.

Current Species Status

The hoary bat is the most widely distributed bat in North America. In Hawaii, the Hawaiian hoary bat (opeapea) has been reported from all the main Hawaiian Islands, except for Niihau, although the specimen records only exist for Kauai, Oahu, Maui, Molokai, and Hawaii Island. On Oahu, the species is thought to be widely distributed however, the highest concentrations of acoustic detections for Hawaiian hoary bat are from northern Koolau and Waianae Mountain ranges (USFWS, 2021g). Additional acoustic detections for the species have been documented on lands in Waikiki, Ford Island, the north shore of Oahu, and the National Wildlife Refuge complex that includes the James Campbell NWR, the Kalaeloa Unit of the Pearl Harbor NWR, and the Oahu Forest NWR (USFWS, 2021g).

Biology and Ecology of Species – Reproduction and Forage Requirements

Hawaiian hoary bats roost alone or with dependent young in native and nonnative trees, typically more than 15 feet tall (USFWS, 2021g). Hoary bats begin foraging before or after sunset depending on the time of year, feed on a variety of native and non-native night-flying insects, including moths, beetles, crickets, mosquitoes, and termites; and similar to other insectivorous bats, prey is located using echolocation (USFWS, 1998). Water courses and edges (e.g., coastlines and forest/pasture boundaries) appear to be important foraging areas; the species also is attracted to insects that congregate near lights. Breeding has only been documented on the islands of Hawaii and Kauai. Mating most likely occurs between September and December, and females give birth to twins during May or June. Mother bats likely stay with their pups until they are six to seven weeks old (USFWS, 1998).

Factors Affecting Species Activity and Survival

Threats to hoary bats include habitat loss, pesticides, predation and roost disturbance. A reduction in tree cover might be the primary reason for the species decline in Hawaii and pesticides may have reduced populations (USFWS, 1998).

Potential to Occur in the Action Area

Little is known about the species' occurrence across the island of Oahu, including the Ala Wai watershed. However, based on the habitat preferences, it is possible that it could occur within the action area. Specifically, the Manoa Valley Park District detention basin, Woodlawn Drive Bridge floodwall, and Koali Road floodwall include forested habitat with tall trees that may be used for roosting. The Makiki Park District detention basin (including the Kanaha floodwall), Kaimuki High School floodwall, Ala Wai Golf Course detention basin, and portions of the Ala Wai Canal floodwall (especially in the vicinity of the Manoa-Palolo Canal) may also provide suitable foraging habitat; however, the habitat value of these sites is likely diminished by the extensive urbanization in the surrounding areas.

Hawaiian Monk Seal (*Monachus schauinslandi*)

The Hawaiian monk seal is a listed federally endangered species. Critical habitat has been designated for Hawaiian monk seal. Specific to Oahu, designated marine critical habitat includes the seafloor and all subsurface waters within 33 feet (10 meters) of the seafloor, out to the 656-foot (200 meter) depth contour line. At specific points around Oahu, critical habitat for Hawaiian monk seal extends inland through the water's edge 16 feet (five meters) into the terrestrial environment from the shoreline. However, no terrestrial critical habitat is designated within the vicinity of the action area.

Current Species Status

Hawaiian monk seals are found in the Hawaiian archipelago which includes both the main and Northwestern Hawaiian Islands and rarely at Johnston Atoll which lies nearly 1,000 miles southwest of Hawaii (NOAA, 2023a). The monk seals are endemic to these islands, occurring nowhere else in the world. The Hawaiian monk seal population is estimated to be around 1,570 seals—nearly 1,200 seals in the northwestern Hawaiian Islands and 400 monk seals in the main Hawaiian Islands. In general, the Hawaiian monk seal population has been declining overall for six decades and current numbers, though increasing, are only about one-third of historic population levels (NOAA, 2023a).

Biology and Ecology of Species – Reproduction and Forage Requirements

Hawaiian monk seals are "generalist" feeders, which means they eat a wide variety of foods depending on what's available (NOAA, 2023a). They eat many types of common fishes, squids, octopuses, eels, and crustaceans (crabs, shrimps, and lobsters). Diet studies indicate that they forage at or near the seafloor and prefer prey that hide in the sand or under rocks. Hawaiian monk seals are mostly solitary and don't live in colonies like sea lions or other seals. But they do sometimes lie near each other—usually not close enough to make physical contacts—in small groups. They usually sleep on beaches, sometimes for days at a time. They also occasionally sleep in small underwater caves. Monk seals do not migrate seasonally, but some seals have traveled hundreds of miles in the open ocean. Individual seals often frequent the same beaches over and over, but they do not defend territories. When on land, monk seals haul-out to rest, molt, give birth and nurse on sand, coral rubble, and volcanic rock shorelines. They generally prefer sandy, protected beaches surrounded by shallow waters for pupping. When not on land, Hawaiian monk seals use waters surrounding atolls and islands and areas further offshore on reefs and submerged banks; they also use deepwater coral beds as foraging habitat (NOAA, 2023a).

Mating occurs during the spring and summer months at sea (76 FR 32026, June 2, 2011). Most females mate once a year. Females and males typically reach sexual maturity between the ages of 5 to 6 years of age in the main Hawaiian Islands and age 7 to 10 in the Northwestern Hawaiian Islands (NOAA, 2023a). The youngest documented female to give birth was 4 years old. Gestation is about 11 months with most pup births occurring between February and August. Nursing lasts for about 6 weeks and pups and moms stay on shore until a pup is weaned (76 FR 32026, June 2, 2011).

Factors Affecting Species Activity and Survival

Historically, humans and disturbance from government installations in the Northwestern Hawaiian Islands threatened Hawaiian monk seal. Today, Hawaiian monk seal are negatively affected by food limitation, shark predation, marine debris entanglement, male seal aggression, habitat loss, fishery interactions (i.e., commercial longline fishing including hook and nets), disease (e.g., canine distemper, Leptospirosis, and Brucellosis) and contaminants, human-seal interactions, and intentional killing (NOAA, 2023a).

Potential to Occur in the Action Area

The Hawaiian monk seal is unlikely to occur within the action area; however, a Hawaiian monk seal was observed swimming in the Ala Wai Canal on March 6, 2023 (Moore, 2023). It is believed that the presence of the Hawaiian monk seal in the canal is potentially related to recent dredging of canal sediments by the Hawaii DLNR and Genki balls that have been thrown into the canal as part of the Genki Ala Wai Project. In addition, a Hawaiian monk seal known as RK96 (also known as Kaiwi) has pupped on Kaimana beach in Waikiki twice (i.e., 2021 and 2023) (NOAA, 2023b). Therefore, there is the potential for Hawaiian monk seals to occur within the action area. It is important to note that the proposed action is focused on stream-related flood risk reduction and does not include any direct impacts to marine or coastal habitat. The proposed action does not extend into the marine critical habitat for the Hawaiian monk seal, and no terrestrial critical habitat is designated within the vicinity of the action area. Overall, there is the potential for Hawaiian monk seal to occur within the action area.

Band-rumped Storm Petrel (*Oceanodroma castro*)

The Hawaii DPS of band-rumped storm-petrel is a listed federally endangered species. No critical habitat has been designated for this species.

Current Species Status

Historically, band-rumped storm-petrels were abundant and occurred throughout the main Hawaiian Islands (USFWS, 2021h). There is thought to be one single population that breeds within the Hawaiian Islands across several colonies. Currently, band-rumped storm-petrels are confirmed or likely breeding on Lehua Islet, Kauai, Lanai, and the island of Hawaii. The species may potentially breed on Maui, but no nesting sites have been confirmed. Population estimates for Hawaii DPS of band-rumped storm-petrel are unknown, but a study estimated between 171 and 221 nesting pairs on Kauai in 2002 (USFWS, 2021h).

Biology and Ecology of Species – Reproduction and Forage Requirements

Band-rumped storm-petrels are ground nesting seabirds, which predominantly nest in cliffs or rocky lava fields (USFWS, 2021h). Eggs are laid in May through June and chicks fledge around October. Band-rumped storm-petrels typically do not begin to breed until between ages three to seven years old. The species can live up to 20 years old. Band-rumped storm-petrels feed while sitting on the water or by dipping prey while flapping just above the surface of the ocean. It is suspected that their diet consists of small fish, squid, and perhaps some crustaceans.

Factors Affecting Species Activity and Survival

Threats to band-rumped storm-petrels include introduced predators such as pigs, rats, feral cats, and mongoose, goats, and sheep degrade nesting habitat (USFWS, 2021h). Artificial lighting may cause fall-out, causing collisions and injuries to individuals that make them vulnerable to predators. Also vulnerable to collisions with towers and utility lines while in flight (USFWS, 2021h).

Potential to Occur in the Action Area

Nesting habitat for the band-rumped storm-petrel is not present within the proposed action footprint, nor is the species known to breed on Oahu. The species could be present foraging or flying over the island as fallout of band-rumped storm-petrels has been recorded on Oahu (USFWS, 2021h).

Hawaii Akepa (*Loxops coccineus*)

Hawaii akepa is a listed federally endangered species. No critical habitat has been designated for this species.

Current Species Status

The historical range of the Hawaii akepa once included much of the island of Hawaii (USFWS, 2010a). At the most recent 5-year review of the species, Hawaii akepa occurred as five disjunct populations in the north and central windward Hawaii, Kau, Kona, and Hualalai regions on Hawaii (USFWS, 2020b). In 1977, the total population of Hawaii akepa was estimated to be 13,892 birds. In 2016, the total population was estimated to be 16,248 birds. Hawaii akepa is known for distributional anomalies across apparently suitable habitat particularly between open canopy montane woodland and old-growth closed-canopy *Metrosideros polymorpha* (ohia) forest, likely due to differences in nest-site and food availability. Overall, recent surveys and population estimates suggest that the Hawaii akepa population is stable and possibly increasing especially in Hakalau Forest National Wildlife Refuge (USFWS, 2020b).

Biology and Ecology of Species – Reproduction and Forage Requirements

The Hawaii akepa is a small, sexually dichromatic Hawaiian honeycreeper endemic to Hawaii island (USFWS, 2010a). Hawaii akepas form monogamous pairs during July and August and bonds last several years. The breeding period of akepas begins in March and ends by September. Females typically lay one to two eggs which are incubated for 14 to 16 days. Females brood the hatchlings for up to 8 days. Juveniles develop plumage by day 12 and young akepas leave the nest around 16 to 20 days after hatching. They remain dependent on their parents for up to 10 weeks post hatching (USFWS, 2010a).

Hawaii akepa are birds of old growth ohia or ohia/koa forest (USFWS, 2010a). Their density depends in part on the density of large trees because only large trees provide the cavities required for nesting. The average size of trees used for nesting is three feet in diameter at breast height. Large ohia trees provide cavities for nest-sites and the preferred foraging substrate for Hawaii akepa. Large koa trees provide mainly cavities for nest sites but not preferred foraging substrate. Hawaii akepa are not typically found below 4,300 feet elevation (USFWS, 2010a).

Hawaii akepa feed on insects and spiders, though their main diet consists of caterpillars. They have been observed feeding on nectar to a lesser extent (USFWS, 2010a).

Factors Affecting Species Activity and Survival

Threats to the survival of this species primarily include modification and loss of habitat and avian disease (USFWS, 2010a). Predation by introduced mammals may also play a role in this species survival. The species is especially sensitive to the loss of old growth forest due to their dependence on large trees with cavities for nesting (USFWS, 2010a).

Potential to Occur in the Action Area

The action area is generally comprised of either low density vegetated non-native riparian/forest habitat (such as that associated with the floodwalls along the middle watershed), turf grass (such as that associated with the detention basins) or developed areas (such as that associated with the floodwalls along the lower watershed). No portion of the action area supports old growth ohia or ohia/koa forest. As such, suitable habitat is not present, and this species is expected to not have the potential to occur within the action area.

Hawaiian Duck (*Anas wyvilliana*)

Hawaiian duck is a listed federally endangered species. No critical habitat has been designated for this species.

Current Species Status

The Hawaiian duck historically occurred throughout the main Hawaiian Islands except the island of Lanai and Kahoolawe (USFWS, 2021d). Today, these birds are only found on Kauai and Niihau and were reintroduced on Oahu, Hawaii, and Maui. During the most recent 5-year review of the species, genomic research indicated that duck populations on the islands of Oahu, Maui, Molokai, and Hawaii are Hawaiian duck-mallard hybrids due to genetic intermixing with feral mallards. However, ducks sampled on Kauai appear to be pure or nearly pure. There are believed to be fewer than 2,000 pure Hawaiian duck remaining statewide, with most of these occurring on Kauai (USFWS, 2021d).

Biology and Ecology of Species – Reproduction and Forage Requirements

Hawaiian ducks are found in a variety of wetland habitats including freshwater marshes and ponds, coastal estuaries and ponds, artificial reservoirs, kalo or taro (*Colocasia esculenta*) lo'i or patches, irrigation ditches, sewage treatment ponds, montane streams, and marshlands (USFWS, 2011). This species is visible from sea level up to 10,827 feet (3,300 meters) of elevation (USFWS, 2021d). The Hawaiian duck was found to occupy wetlands greater than 1,969 feet (600 meters) more likely from a house in areas of low building densities and are more likely to occupy medium to large wetlands (greater than 10,764 square feet [1,000 square meters]) in areas of high wetland densities (USFWS, 2009).

Hawaiian ducks are serially monogamous (USFWS, 2021d). Some pairs nest year-round, but the main breeding season takes place from December to May. The female lays 2 to 10 eggs and incubation lasts about 4 weeks. Ducklings are precocial and can take to the water soon after hatching but cannot fly until about 9 weeks of age. They become reproductively mature enough to reproduce after a year of age (USFWS, 2021d).

Hawaiian ducks are omnivorous birds (USFWS, 2021d). Their diet consists of freshwater vegetation, mollusks, insects, and other aquatic invertebrates (USFWS, 2021d).

Factors Affecting Species Activity and Survival

Major threats affecting the survival of this species include hybridization with feral mallards (*Anas platyrhynchos*); loss and degradation of wetland habitat including alteration of hydrology, and invasion of habitat by nonnative plants; predation and avian disease; and environmental contaminants (USFWS, 2009).

Potential to Occur in the Action Area

The only suitable habitat that could support this species within the action area are very small pockets of wetland habitat; these are limited to isolated features within the Ala Wai golf course, and possibly Hausten Ditch and the upper reaches of the Ala Wai Canal. However, these areas are in high building densities and are small, and therefore are expected to provide very minimal habitat value in comparison to other nearby wetland areas (e.g., Pearl Harbor National Wildlife Refuge). Overall, these areas are not expected to provide suitable nesting habitat but could be used for resting habitat by Hawaiian ducks. As such, it is possible (though unlikely), that Hawaiian ducks could occur in the action area.

Hawaiian Common Gallinule (*Gallinula galeata sandvicensis*)

Hawaiian common gallinule is a listed federally endangered species. Critical habitat has not been designated for this species.

Current Species Status

Hawaiian gallinule (Alae ula) occurs in wetland habitats below 410 feet elevation on the islands of Kauai and Oahu, although there have been reports from Keanae Peninsula on Maui and from the island of Hawaii (USFWS, 2010b). On Oahu, the species is widely distributed with most birds found between Haleiwa and Waimanalo; small numbers occur at Pearl Harbor and the leeward coast at Lualualei Valley. Island-wide population, based on semi-annual waterbird counts conducted by DOFAW, suggests that the population is increasing, but count numbers are variable, about 300 individuals. Currently, the Hawaiian gallinule occurs only on the islands of Kauai and Oahu having been extirpated from Molokai sometime after the 1940s, from Maui after the late 1940s, and from the island of Hawaii in 1887 (USFWS, 2021a). As of the most recent 5-year review for the species, it was estimated that the minimum population is approximately 927 individuals (USFWS, 2021a).

Biology and Ecology of Species – Reproduction and Forage Requirements
Hawaiian gallinules are found in a variety of wetland habitats including freshwater marshes and ponds, coastal estuaries and ponds, artificial reservoirs, kalo or taro (*Colocasia esculenta*) lo'i or patches, irrigation ditches, and sewage treatment ponds (USFWS, 2011e).

Nesting occurs year-round, but most activity occurs between March and August (USFWS, 2010b). Platform nests are constructed in dense vegetation over water. Five to six eggs are laid and hatch after 22 days. Chicks can swim shortly after hatching and are dependent on their parents for several weeks (USFWS, 2010b).

Hawaiian gallinules are thought to be opportunistic feeders, so their diet may vary with the particular habitat (USFWS, 2010b). They generally forage in dense emergent vegetation and along the edges of habitat (USFWS, 2010b).

Factors Affecting Species Activity and Survival
Threats to survival for this species include loss and degradation of wetland habitat; predation by introduced animals; modification of hydrology; alteration of habitat structure and vegetation composition by invasive nonnative plants; loss of riparian vegetation; and water quality degradation due to grazing, disease, and possibly environmental contaminants (USFWS, 2011e).

Potential to Occur in the Action Area
The only suitable habitat that could support this species within the action area are very small pockets of wetland habitat; these are limited to isolated features within the Ala Wai golf course, and possibly Hausten Ditch and the upper reaches of the Ala Wai Canal. However, these areas lack some of the key habitat features, and therefore are expected to provide very minimal habitat value in comparison to other nearby areas (e.g., Pearl Harbor National Wildlife Refuge); these areas are not expected to provide suitable nesting habitat but could be used for resting habitat. As such, it is possible (though unlikely), that Hawaiian gallinule could occur in the action area.

Hawaiian Coot (*Fulica americana alai*)
Hawaiian coot is a listed federally endangered species. Critical habitat has not been designated for this species.

Current Species Status
Hawaiian coot (ala keokeo) occurs statewide, although Kauai, Oahu, and Maui collectively support 80% of birds detected during the annual waterbird surveys (USFWS, 2021b). On Oahu, coots are observed at Lake Wilson and Nuuanu Reservoir, Kahuku Point and along the

windward shore. The most recent minimum population estimate of Hawaiian coot is 1,815 individuals (USFWS, 2021b).

Biology and Ecology of Species – Reproduction and Forage Requirements

Hawaiian coots are found in a variety of wetland habitats including freshwater marshes and ponds, coastal estuaries and ponds, artificial reservoirs, kalo or taro (*Colocasia esculenta*) lo'i or patches, irrigation ditches, and sewage treatment ponds (USFWS, 2011e). Hawaiian coot are omnivores, feeding on seeds and leaves, snails, crustaceans, insects, tadpoles, and small fish. The species will travel long distances, including between islands, when local food sources are depleted. Nesting habitat includes freshwater and brackish ponds, irrigation ditches, and taro fields. Floating nests are constructed of aquatic vegetation and found in open water or anchored to emergent vegetation. Open water nests are usually composed of mats of water hyssop and Hilo grass. Nests in emergent vegetation are typically platforms constructed from buoyant stems of species such as bulrush. Nesting occurs year-round, but most activity occurs between March and September. Clutch size ranges from three to ten eggs, and chicks may hatch after a 25-day incubation period (USFWS, 2011e).

Factors Affecting Species Activity and Survival

Threats to survival for this species include loss and degradation of wetland habitat; predation by introduced animals; modification of hydrology; alteration of habitat structure and vegetation composition by invasive nonnative plants; loss of riparian vegetation; and water quality degradation due to grazing, disease, and possibly environmental contaminants (USFWS, 2011e).

Potential to Occur in the Action Area

The only suitable habitat that could support this species within the action area are very small pockets of wetland habitat; these are limited to isolated features within the Ala Wai golf course and possibly along the upper edges of the Ala Wai Canal. However, these areas are very small and provide very minimal habitat value in comparison to other nearby areas (e.g., Pearl Harbor National Wildlife Refuge); they are not expected to provide suitable nesting habitat but could be used for resting habitat. As such, it is possible (though unlikely), that Hawaiian coots could occur in the action area.

Hawaiian Petrel (*Pterodroma sandwichensis*)

Hawaiian petrel is a listed federally endangered species. No critical habitat has been designated for this species.

Current Species Status

Historically, the Hawaiian petrel was believed to have had well established breeding populations on all the major Hawaiian Islands (USFWS, 1983). Currently, the Hawaiian petrel (Uau) breeds on several main Hawaiian Islands, including Maui, Hawaii Island, and Kauai and possibly on Molokai, Lanai, the sea stacks off Kahoolawe and Lehua Island (USFWS, 2011c). However, approximately 85% of the known population of Hawaiian petrel nests on Maui (USFWS, 2011c). Since the last 5-year review in 2017, Pacific Rim Conservation continues to conduct surveys and burrow searching in the northern Koolau Mountains and near the summit of Mount Kaala on Oahu (USFWS, 2022a). No burrows have been located yet, but Hawaiian petrel calls continue to be detected on acoustic monitors at both sites (USFWS, 2022a). An analysis of at-sea surveys conducted between 1998 and 2011 estimated the Hawaiian petrel population to be 52,186 individuals including juveniles and subadults (USFWS, 2022a).

Biology and Ecology of Species – Reproduction and Forage Requirements

Hawaiian petrels currently are known to nest only at elevations above 7,200 feet (USFWS, 1983). Vegetation in nesting areas is often sparse and consists predominantly of grass and bracken fern. Adults form nests by excavating burrows or crevices that are generally three to six feet deep and reaching a length up to 15 feet or more. Nesting burrows are commonly located among large rock outcrops, talus slopes, or along edges of lava flows with suitable underlying soil for the excavation of tunnels. Hawaiian petrels form long-term pair bonds and return to the same nest site each year during breeding season. Eggs are laid in May through June and chicks generally fledge by December. Both parents incubate, brood, and feed a single chick. Hawaiian petrels begin breeding at about age 5 or 6 (USFWS, 1983).

Hawaiian petrels may feed hundreds of miles (thousands of kilometers) from their colonies, preying upon marine organisms, such as squid, goatfish, lantern fish and in some cases, crustaceans. Petrels feed by capturing prey with their beaks while sitting on the water or flapping just above the surface.

Factors Affecting Species Activity and Survival
Threats to the survival of Hawaiian petrels include historic hunting and introduced predators, such as dogs, pigs, rats, feral cats, and mongoose (USFWS, 1983).

Potential to Occur in the Action Area
Nesting habitat for the Hawaiian petrel is not present within the proposed action footprint. Therefore, no direct impacts to Hawaiian petrel or their nesting/foraging habitat is expected to occur. The species could be present foraging or flying over the action area.

Hawaiian Stilt (*Himantopus mexicanus knudseni*)
Hawaiian stilt is a listed federally endangered species. Critical habitat has not been designated for this species.

Current Species Status
Hawaiian stilts were historically known from all of the major islands except Lanai and Kahoolawe (USFWS, 2011e). Currently, Hawaiian stilts are found on all the main Hawaiian Islands except Kahoolawe. Regarding Oahu, large concentrations of Hawaiian stilts can be found at the James Campbell National Wildlife Refuge, the Kahuku aquiculture ponds, the Honouliuli and Waiawa units of the Pearl Harbor National Wildlife Refuge, and on Nuupia Ponds in Kaneohe. Populations also exist at the Chevron Refinery, the fishponds at Kualoa Beach Park, at Salt Lake District Park, and at scattered locations along the northern and eastern coasts. From 2006 to 2011, Oahu accounted for 35 to 50% of the State's Hawaiian stilt population (USFWS, 2011e). The most recent winter and summer surveys for Hawaiian stilt show a fluctuating population, which generally increased from 1985 to 2004 and since then has been roughly stable at 1,500 to 2,000 individuals (USFWS, 2020c).

Biology and Ecology of Species – Reproduction and Forage Requirements
Hawaiian stilts are found in a variety of wetland habitats including freshwater marshes and ponds, coastal estuaries and ponds, artificial reservoirs, kalo or taro (*Colocasia esculenta*) lo'i or patches, irrigation ditches, and sewage treatment ponds (USFWS, 2011e). Foraging habitat consists of ephemeral fresh, brackish, or saltwater habitats. Hawaiian stilts prefer sites with a water depth of less than nine inches, limited and low growing vegetation, or exposed tidal flats and opportunistically prey upon polychaete worms, small crabs, insects, and small fish. Hawaiian stilt frequently moves among wetland habitats in search of food (USFWS, 2011e).

Breeding habitat differs from foraging habitat and individuals move between the two habitats daily (USFWS, 2011e). Nesting occurs on freshly exposed mudflats and some low growing vegetation, also will nest on islands in fresh and brackish ponds or artificial floating nest structures. Nesting occurs between March and August and peaks in May and June. Three to four eggs are typically laid, and chicks hatch approximately 24 days later. Both parents incubate eggs and brood young, and fledglings remain with their parents for several months (USFWS, 2011e).

Factors Affecting Species Activity and Survival

Threats to survival for this species include loss and degradation of wetland habitat; predation by introduced animals; modification of hydrology; alteration of habitat structure and vegetation composition by invasive nonnative plants; loss of riparian vegetation; and water quality degradation due to grazing, disease, and possibly environmental contaminants (USFWS, 2011e).

Potential to Occur in the Action Area

A small amount of potentially suitable habitat occurs within the action area; these areas include the aquatic features within the Ala Wai golf course, Hausten Ditch, and possibly the upper reaches of the Ala Wai Canal. However, these areas are limited in size and provide very minimal habitat value in comparison to other nearby areas (e.g., Pearly Harbor National Wildlife Refuge); they are not expected to provide suitable nesting habitat but could be used for resting habitat. As such, it is possible (though relatively unlikely), that Hawaiian stilts could occur in the action area.

Newell's Townsend's Shearwater (*Puffinis auricularis newelli*)

The Newell's shearwater is a listed federally threatened species.

Current Species Status

Newell's shearwater's historical range is thought to include Hawaii, Maui, Molokai, Oahu, and Kauai. Young et al., (2019) have identified sites on the leeward slopes of Mount Kaala in the Waianae Mountains and at Poamoho, Koolau Mountains, that may serve as breeding sites on Oahu. Since the publication of the 5-year review in 2011, results from analysis of at-sea surveys conducted between 1998 and 2011 estimated the Newell's shearwater population to be about 27,011 (95% confidence interval [CI] 18,254 – 37,125) individuals, including juveniles and subadults. The previous at-sea population estimate from surveys conducted between 1980 and 1994 estimated 84,000 (95% CI 57,000 – 115,000) birds, including subadults and juveniles.

Biology and Ecology of Species – Reproduction and Forage Requirements

Newell's shearwaters are colonial and nesting habitat is typically within steep mountainous terrain between 500 and 2,300 feet in elevation (USFWS, 1983). The species appears to have an affinity for dense fern habitat with moderate to light tree cover. To take flight, the species requires an open downhill flight path through which it can become airborne; therefore, the species favors ridge crests or embankments for its nesting burrows. Females typically lay a single egg in cavities and burrows, often located at the base of a tree. Breeding is highly synchronous, and eggs are laid in early June, and most young fledge by November. Both parents incubate the egg, and brood and feed the nestling. Parents forage tens of miles (hundreds of kilometers) offshore and return to colon at night to feed chick. No post-fledging care is provided. Age at first breeding is between 6 and 7 years old (USFWS, 1983).

Newell's shearwater often forages in large, mixed species flocks associated with schools of large, predatory fishes, which drive prey to the surface (USFWS, 1983). The species feeds

mainly by pursuit-plunging; individuals dive into water and swim using their partly folded wings for propulsion. Diet may consist of fish and squid (USFWS, 1983).

Factors Affecting Species Activity and Survival

Threats to Newell's shearwater include historical hunting, introduced predators such as dogs, pigs, rats, barn owls, feral cats, and mongoose. Habitat loss and degradation has resulted in the loss of 75% of forest habitat over the last 150 years, with much of the remaining forest degraded by invasive plants. Artificial lighting disorients fledglings, causing "fallout" and collision with vertical structures. When grounded, fledglings become susceptible to predators. Overfishing and catastrophes, such as hurricanes, may result in injury and mortality to individuals.

Potential to Occur in the Action Area

Nesting habitat for Newell's shearwater is not present within the proposed action area. Therefore, no direct impacts to Newell's shearwater or their nesting/foraging habitat is expected to occur. The species could be present foraging or flying over the action area.

Short-tailed Albatross (*Phobastria (=Diomedea) albatrus*)

The short-tailed albatross is a listed federally endangered species. No critical habitat has been designated for this species.

Current Species Status

Historically, the short-tailed albatross is believed to have once nested on Midway Atoll at the northwestern end of the Hawaiian Archipelago (USFWS, 2008). Since 1938, approximately 50 observations of about 17 different short-tailed albatrosses have been noted in the vicinity of the Northwestern Hawaiian Islands, typically between November and April (USFWS, 2008). During the most recent 5-year review it was noted that in the Northwestern Hawaiian Islands, a short-tailed albatross pair was present on Eastern Island at Midway Atoll from 2008 to 2015 and successfully fledged chicks in 2011, 2012, and 2014 (USFWS, 2020d). During 2016, a new pair formed on Sand Island, Midway Atoll. During the 2018-2019 breeding season, the same pair returned and successfully raised their own chick to fledge. A suspected female-female pair has been attempting to breed at Kure Atoll, Hawaii, since 2010 (USFWS, 2020d). The most recent 5-year review of the species estimated the population at 7,365 birds.

Biology and Ecology of Species – Reproduction and Forage Requirements

Breeding habitat for the species is isolated, windswept, offshore islands, with restricted human access (USFWS, 2008). Nest sites may be flat or slopes, with sparse or full vegetation. The short-tailed albatross is a colonial, annual breeding species; each breeding cycle lasts about eight months. Nests consist of a divot on the ground lined with sand and vegetation. Birds may breed at 5 years of age, but first year of breeding is more commonly six. A single egg is laid in late October to late November with hatching occurring from late December through January. Chicks begin to fledge in late May into June (USFWS, 2008).

Non-breeding habitat is the North Pacific marine environment which is most heavily used by short-tailed albatross (USFWS, 2008). The area is characterized by regions of upwelling and high productivity along the northern edge of the Gulf of Alaska, along the Aleutian Chain, and along the Bering Sea shelfbreak from the Alaska Peninsula out towards St. Matthew Island (USFWS, 2008).

The diet of short-tailed albatross during breeding is not well-known, but observations of food brought to nestlings and of regurgitated material indicate that the diet includes squid, shrimp, fish, flying fish eggs, and other crustaceans (USFWS, 2008).

Factors Affecting Species Activity and Survival

Major threats to short-tailed albatross include habitat alteration and loss due to catastrophic events; climate change; commercial fishing; contaminants; disease and parasites; predation; natural competition; invasive species; air strikes; and other human activities (USFWS, 2008).

Potential to Occur in the Action Area

The action area is generally comprised of either low density vegetated non-native riparian/forest habitat (such as that associated with the floodwalls along the middle watershed), turf grass (such as that associated with the detention basins) or developed areas (such as that associated with the floodwalls along the lower watershed). No portion of the action area supports suitable breeding habitat for short-tailed albatross. As such, suitable habitat is not present, and this species is expected to not have the potential to occur within the action area.

Green Sea Turtle (*Chelonia mydas*)

The green sea turtle, Central North Pacific Distinct Population Segment is a listed federally threatened species. The National Marine Fisheries Service (NMFS) has proposed to designate specific areas in the marine environment as critical habitat for six distinct population segments (DPSs) of the green sea turtle, including the Central North Pacific DPS, under the Endangered Species Act of 1973, as amended. Proposed critical habitat includes nearshore areas from the mean high-water line to 66-foot (20 meters) depth located along the coasts of Florida, North Carolina, Texas, Puerto Rico, U.S. Virgin Islands, California (which also includes nearshore areas from the mean high-water line to 6 miles [10 kilometers] offshore), Hawaii, American Samoa, Guam, and the Commonwealth of Northern Marian Islands. It also includes Sargassum habitat, from 33-foot (10 meters) depth to the outer boundary of the U.S. Exclusive Economic Zone, in the Gulf of Mexico and Atlantic Ocean (NOAA-NMFS-2023-0087). The proposed designated critical habitat includes the mouth of the Ala Wai Canal, the Ala Wai Canal Boat Harbor, and the nearshore marine environment within the vicinity of Waikiki which could experience indirect impacts from the proposed action.

Current Species Status

The green sea turtle occurs throughout the Hawaiian Islands and are most conspicuous at French Frigate Shoals (NMFS and USFWS, 1998). Green sea turtles also inhabit the nearshore waters around the main Hawaiian Islands, including Oahu. The Hawaiian green turtle population (i.e., the Central North Pacific DPS) has been increasing at a rate of 5% per year over the past two decades (NMFS and USFWS, 1998).

Biology and Ecology of Species – Reproduction and Forage Requirements

Adult green sea turtles reside in nearshore benthic environments and have a nearly exclusive herbivorous diet consisting of macroalgae and sea grasses (NMFS and USFWS, 1998). Green sea turtles are commonly observed to forage for sea grass (*Halophila decipiens*) at Ala Moana Beach Park, Oahu Island. Adult male and female green sea turtles have been observed to haul out and bask on the shoreline at French Frigate shoals. About 90% of the nesting occurs on French Frigate Shoals of the Northwestern Hawaiian Islands. Between 200 and 700 females nest at French Frigate Shoals annually with a modest amount of nesting at Laysan Island, Lisianski Atoll, and Peal and Hermes Reef. Green sea turtles in Hawaii may lay up to six

clutches of eggs per season and each clutch may consist of about 100 eggs (NMFS and USFWS, 1998).

Factors Affecting Species Activity and Survival
Threats to the survival of GST include the loss of foraging habitat to nearshore development in the main Hawaiian Islands (e.g., marina construction, artificial beach development, siltation from agricultural runoff, contamination of forage areas from toxic spills, resort development, and increased vessel traffic), entanglement and ingestion of marine debris, incidental take during fisheries, poaching, and disease (e.g., fibropapillomas) (NMFS and USFWS, 1998).

Potential to Occur in the Action Area
The green sea turtle is likely to occur within the action area, specifically the Ala Wai Canal and potentially as far upstream as the Manoa-Palolo Canal. Green sea turtle has been observed as recently as 2021 in the Ala Wai Canal.

Hawksbill Sea Turtle (*Eretmochelys imbricata*)
The hawksbill sea turtle is a listed federally endangered species. Critical habitat has been designated in the waters surrounding Mona and Monito Islands, Puerto Rico. No critical habitat is present within the action area.

Current Species Status
Hawksbill sea turtles may occur throughout the main Hawaiian Islands but are considered rare except for common observations of individuals around West Maui. Approximately 60 female adults have been documented within Hawaiian waters with no estimate of population size.

Biology and Ecology of Species – Reproduction and Forage Requirements
Adult hawksbill sea turtles forage on sponges and certain species of algae. They are observed in shallow reefs and bays. Nesting has been documented along Halawa River Valley of east Molokai Island, Kamehameha Beach, Hawaii Island, and various beaches around Maui Island. Hawskbill turtles display slow growth rates with an average annual growth rate of approximately 0.39 to 1.97 inches (two to five centimeters) per year for juveniles that slows to almost no somatic growth in adults.

Factors Affecting Species Activity and Survival
Threats to hawksbill sea turtle include the loss of nesting beaches due to construction and human presence, beach erosion, artificial lighting, nest predation, exotic vegetation, marine debris, incidental take during from fisheries, poaching, and disease (e.g., fibropapillomas).

Potential to Occur in the Action Area
The hawksbill sea turtle is less likely to occur within the action area when compared to the green sea turtle; however, the possibility exists that the species could be present in the Ala Wai Canal and potentially as far upstream as the Manoa-Palolo Canal.

3.4.5 Essential Fish Habitat
Essential Fish Habitat (EFH) in the marine waters surrounding the Hawaiian Islands is described in two fishery ecosystem plans (FEPs) prepared by the Western Pacific Regional Fishery Management Council (WPRFMC). The FEP for the Hawaiian Archipelago (2009; Amendment 4, 2016; Amendment 5, 2019) specifically manages demersal resources and habitats associated with the extended Hawaiian Islands. Fisheries may comprise a group or complex of species. These fishery species are collectively referred to as management unit species (MUS).

The adjacent marine waters of Ala Wai Small Boat Harbor and the nearshore marine waters of Honolulu (Figure 22) are within the Hawaii Archipelago Fishery Ecosystem Plan (FEP) boundaries and has been identified as EFH by the WPRFMC. MUS are those "caught in quantities sufficient to warrant management or specific monitoring by NMFS and the WPRFMC," are listed in Table 34. The EFH for MUS of the Western Pacific Region (Table 35 and Table 36) are bounded by the shoreline and seaward boundary of the exclusive economic zone (EEZ), unless otherwise indicated.

Figure 22: EFH (Yellow Highlight) within the Vicinity of the Study Area.

Table 34: Hawaii Archipelago Management Unit Species (MUS).

Scientific Name	Common Name	Local Name
Bottomfish		
Aphareus rutilans	silverjaw jobfish	lehi
Aprion virescens	gray jobfish	uku
Hyporthodus quernus	sea bass142ompu'upu'u

Table 35: Bottomfish and Seamount Groundfish EFH Designations for Each Life Stage of Species Assemblages.

Species Assemblage	EFH				Overlaps with Action Area?
	Eggs	Post-hatch Pelagic	Post-settlement	Sub-adult/adult	
Bottomfish Shallow Stocks	• Water column from 0-240 m (0-787 ft) • Shoreline to EEZ outer boundary				Yes
Bottomfish Intermediate Stocks	• Water column from 0-320 m (0-1,050 ft) • Shoreline to EEZ outer boundary		• Water column from 40-320 m (131-1,050 ft) • Between the 40 and 320 m (131 and 1,050 ft) isobaths		• Yes – Eggs & Post-hatch pelagic • No – Post-settlement & sub-adult/adults
Bottomfish Deep Stocks	• Water column from 0-400 m (0-1,312 ft) • Shoreline to EEZ outer boundary		• Water column from 80-400 m (262-1,312 ft) • Shoreline to 1,312 ft (400 m) isobath		
Seamount Groundfish	• Pelagic waters 0-600 m (0-1,968 ft) • Within EEZ north of 28° N & west of 180° W		• Benthic or benthopelagic waters from 120-600 m (394-1,968 ft) • Within EEZ north of 28° N & west of 180° W	• Benthic or benthopelagic waters from 120-600 m (394-1,968 ft) • Within EEZ north of 28° N & west of 180° W	

Table 36: Pelagic and Crustacean EFH Designations for Each Life Stage of Species Assemblages.

Species Assemblage	EFH Designations		Overlaps with Action Area?
	Eggs & Larvae	Juveniles & Adults	
Crustaceans	**Kona crab:** • Water column down to 150 m • Shoreline out to EEZ boundary	**Kona crab:** • Bottom from shoreline down to 100 m	Yes
	Deepwater shrimp:	**Deepwater shrimp:**	No

	• Outer reef slopes between 550 and 700 m	• Outer reef slopes between 300 and 700 m	
Pelagic	• Water column down to 200 m • Shoreline to EEZ boundary	• Water column down to 1,000 m • Shoreline to EEZ boundary	Yes

While pelagic MUS can be found within the Hawaii Archipelago FEP boundary, they are managed under a separate Pelagic FEP, which encompasses all areas of pelagic fishing operations in the EEZ or on the high seas, for any domestic vessels that: fish for, possess, or transship Pacific Pelagic MUS (Table 37) within the EEZ waters of the Western Pacific Region or land Pacific Pelagic MUS within the states, territories, commonwealths, or unincorporated U.S. island possessions of the Western Pacific Region.

Table 37: Pacific Pelagic Management Unit Species (PMUS).

Scientific Name	Common Name
Thunnus alalunga	albacore tuna
Thunnus obesus	bigeye tuna
Thunnus albacares	yellowfin tuna
Thunnus thynnus	northern bluefin tuna
Katsuwonus pelamis	skipjack tuna
Euthynnus affinis	kawakawa
Auxis spp.	other tuna relatives
Scomber spp.	other tuna relatives
Allothunus spp.	other tuna relatives
Tetrapturus audax	striped marlin
Tetrapturus angustirostris	shortbill spearfish
Xiphias gladius	swordfish
Istiophorus platypterus	sailfish
Makaira mazara	blue marlin
Makaira indica	black marlin
Alopias pelagicus	pelagic thresher shark
Alopias superciliousus	bigeye thresher shark
Alopias vulpinus	common thresher shark
Carcharhinus falciformis	silky shark
Carcharhinus longimanus	oceanic whitetip shark
Prionace glauca	blue shark
Isurus oxyrinchus	shortfin mako shark
Isurus paucus	longfin mako shark
Lamna ditropis	salmon shark
Coryphaena spp.	mahimahi (dolphinfish)
Lampris spp.	moonfish
Acanthocybium solandri	wahoo
Gempylidae	oilfish family
Bramidae	pomfret family
Ommastrephes bartamii	neon flying squid
Thysanoteuthis rhombus	diamondback squid
Sthenoteuthis oualaniensis	purple flying squid

Based on the depth and distances from shore, EFH for the fisheries listed above is designated, at least in part, in the study area. There is no designated Habitat Area of Particular Concern in or near the study area for any of the federally managed fishery species. Based on the National Oceanic and Atmospheric Administration Office of Coast Survey reported Maritime Limits and Boundaries, the approximate area of cumulative EFH designations for the Hawaii Archipelago and Pelagic Fishery, from the shoreline to the EEZ, measures over 16 million acres of the Pacific Ocean.

3.4.7 Conservation Plans

Habitat Conservation Plans (HCPs) are designed to conserve and protect federally listed and unlisted species while allowing for changes or alterations to wildlife habitats. They are developed by any non-federal landowner in cooperation with the USFWS when certain project activities may result in the take of a listed species. While there are five approved HCPs in place within Oahu, none of the HCPs fall within the study area (DLNR-DOFAW, 2022).

Significance Criteria

Effects on natural environment resource categories would be considered significant if the proposed project would result in any of the following:

- Have a substantial adverse effect on any species identified as a candidate, sensitive, or special status species in local or regional plans, policies, or regulations, or by the Hawaii DLNR or USFWS.
- Have a substantial adverse effect on any riparian habitat or other sensitive natural community identified in local or regional plans, policies, regulations or by the Hawaii DLNR or USFWS.
- Interfere substantially with the movement of any native resident or migratory fish or wildlife species or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites.
- Conflict with any local policies or ordinances protecting environmental resources.
- Conflict with the provisions of an adopted HCP or other approved local, regional, or state habitat conservation plan.

Environmental Consequences

No Action Alternative

Under the No Action Alternative, no flood risk management measures would be implemented and as such, project-related impacts to biological resources would not occur. In the absence of flood reduction measures, it is anticipated that areas adjacent to streams within the Ala Wai Watershed would be subject to periodic flooding.

In general, future climate changes are expected to result in habitat loss and degradation, decreased biodiversity (including extinction of endangered species and migration and loss of native species), and spread of invasive species. However, these conditions are already prolific within the watershed; therefore, it is expected that the future without-project conditions would be commensurate with existing conditions. Specifically, it is expected that the measure sites would continue to be characterized by a suite of non-native (including invasive) species that typically occur in disturbed urban environments. While there may be some slight changes in localized conditions, the overall species composition and habitat structure is not expected to change dramatically over the period of analysis.

Based on the extent of existing urbanization and development within the Ala Wai Watershed, and more specifically along the streams, it is expected that further development would be minimal. Some degree of redevelopment may occur in the neighborhoods throughout the watershed, however, this is not expected to substantially affect biological resources. With respect to instream habitat, it is assumed that there would be no significant changes in the extent and degree of channel hardening or modifications.

Alternative 1

Less than Significant Impact with Environmental Commitments Incorporated:

Plant Communities

Construction of Alternative 1 would involve clearing and trimming of vegetation within the construction limits (including any associated staging and access roads) at each of the structural measure sites. Of this area, vegetation would be permanently displaced with the construction of the Kanaha floodwall, Woodlawn Drive floodwall, Koali Road floodwall, and Kaimuki High School floodwall. Vegetation would also be permanently displaced with the construction of the road closure structures associated with the floodwalls and inlets/outlets. Vegetation within the Makiki District Park detention basin, Manoa Valley District Park detention basin, and Ala Wai Golf Course detention basin would be temporarily displaced during construction. Excavation of the two park district detention basins would temporarily impact turf grass. Construction of the earthen berms around the two park district detention basins and the golf course would also temporarily impact turf grass. Once construction is completed, the earthen berms would be reseeded with native grass species (where practicable). The long-term operation and maintenance of the structural features would need to be maintained in accordance with Corps of Engineers Engineering Pamphlet (EP) 1110-2-18. EP 1110-2-18 requires that a minimum 15-feet down slope of a floodwall, including earthen berms, needs to be a vegetation free zone (VFZ). The VFZ applies to all vegetation except for grasses for the purpose of erosion control.

The approximate areas that would be impacted are summarized in Table 38.

Table 38: Summary of Disturbance Acres for Alternative 1 Measures.

Structural Feature	Total Construction Area (acres)	Permanent Footprint (acres)	Vegetation Management Area for O&M (acres)	Inundation Area During Flood (acres)
Makiki District Park Detention Basin	8.46	6.77	6.77	2.26
Manoa Valley District Park Detention Basin	18.87	29.04	29.04	13.08

TOTAL	**74.52**	**233.80**	**233.79**	**183.96**

The vegetation that would be impacted is predominantly comprised of non-native species, many of which are considered invasive. Native species present within the measure sites are commonly occurring throughout Hawaii, no federally listed plant species are expected to be present.

In general, impact to non-native vegetation is not considered to be significant. However, some of this vegetation may provide habitat for aquatic and other wildlife species within the watershed, such that impacts to the vegetation could affect the wildlife species. Specifically, riparian vegetation, even if non-native and/or invasive, still provides shade and cover that contributes to habitat quality for native stream species. Similarly, non-native tree species may still provide habitat for native birds or bats.

Although impacts to vegetation are generally expected to be less than significant, construction of the project could affect a few concentrations of native species. Specifically, this includes a series of niu and milo trees planted along the Ala Wai Canal. To the extent, these trees would be avoided during construction. Where impacts cannot be avoided, the individual trees would either be replaced in-kind following construction or relocated to a suitable location near the alternative footprint. The exact location and total numbers of trees to be affected and replaced/relocated would be determined as part of pre-construction surveys.

Following construction, long-term operation and maintenance of the project would require ongoing vegetation management, including clearing and trimming in select locations. Specifically, a 15-foot-wide buffer around the perimeter of the detention structures and floodwalls would be revegetated with a suitable grass species; vegetation management would involve mowing the grass and removing any woody vegetation. Vegetation along the access roads would also be periodically trimmed, as needed to maintain adequate clearance for access. The estimated area in which vegetation will be maintained is provided in Table 39. As the areas to be maintained are within the construction limits, they will have been previously disturbed as part of the construction (and revegetated, as appropriate); no sensitive species are expected to colonize these areas. Therefore, maintenance of these areas is not expected to result in more than minimal vegetation-related impacts.

During flood conditions, the detention basins (i.e., Makiki District Park, Manoa Valley District Park, and Ala Wai Golf Course) would occasionally be used to store flood waters, and vegetation within the inundation zone could be temporarily impacts by the floodwaters. The approximate extent of vegetated areas that would be inundated (based on the 20-year event) is summarized in Table 38. The inundation period would be relatively short (in general, about 24 hours for the Makiki and Manoa Valley District Park detention basins; and about 48 hours for the Ala Wai Golf Course detention basin). Given the short duration of inundation, coupled with the lack of sensitive vegetation resources in these areas, operation of the detention basins is not expected to significantly affect vegetation resources.

Invasive plants, such as Java plum, strawberry guava, swamp mahogany, and albizia, are widespread within the alternative action area. Given the prevalence of these species, implementation of the project is not expected to result in a significant increase in the distribution or spread of invasive plant species within the sites. However, construction of the project could potentially result in the introduction of new invasive plant species within the site. However, construction of the project could potentially result in the introduction of new invasive species to

the construction site. To minimize this potential impact, the following BMPs would be implemented:

- All construction equipment, materials, and vehicles arriving from outside of the island of Oahu would be washed and/or visually inspected (as appropriate) for excessive debris, plant materials, and invasive or harmful non-native species before transportation to the construction site; import of materials that are known or likely to contain seeds or propagules of invasive species that would be prohibited.
- Offsite sources of vegetation materials (such as seed mixes) would be certified as weed-free or inspected before transport to the alternative footprint.
- All areas that are hydroseeded would be monitored for six months after hydroseeding to identify invasive plants that establish from seeds inadvertently introduced as part of the seed mix; all invasive plants identified within the hydroseed areas would be removed.
- At the end of the construction period, areas impacted by construction of the project would be surveyed to confirm that no problematic and/or invasive species has been introduced and become established. Appropriate remedial actions would be undertaken to facilitate containment or eradication of the target species as soon as reasonably possible.

Based on the prevalence of non-native species and lack of sensitive vegetation resources, coupled with the environmental commitments and BMPs to replace/relocate native species and minimize the introduction of invasive species, impacts to vegetative resources are expected to be less than significant.

Wildlife Communities

Wildlife resources that occur (or could potentially occur) within the watershed include a suite of native aquatic and terrestrial species, some of which are federally and state listed as endangered. Impacts to these resources are specifically addressed in the subsections below. In general, other wildlife is comprised of non-native and/or invasive species, although a limited number of non-listed native species could occur (e.g., native birds). Potential effects to non-listed native terrestrial species could include both direct impacts (e.g., disturbance, collision with project vehicles, etc.) and indirect impacts associated with habitat loss. However, non-listed native terrestrial species that occur in the alternative action area are generally common and widespread on Oahu, such that direct impacts would not significantly reduce the local population. The proposed project would reduce the amount of habitat available for these species, which could result in the displacement of some individuals. However, the amount of affected habitat represents a very small part of the total range available to each species. Consequently, impacts to non-listed terrestrial species are not considered significant.

Potential impacts to non-native wildlife species are not considered significant. Many of the potentially impacted species have been identified as invasive, which are species that are considered likely to cause economic or environmental harm or harm to human health (EO 13112). For example, feral pigs are generally considered to be a threat to ecosystems as they often consume or trample native flora and fauna, accelerate erosion, alter soil properties, and promote the invasion of non-native plants (Stone et al., 1992; Courchamp et al., 2003). Invasive bird species aggressively chase and outcompete native species for food and space; they also spread the seeds of invasive plant species. As such, adverse impacts to invasive species could be considered a positive effect, although given the scale of the project, any change in local populations is likely to be so low as to be insignificant.

Aquatic Communities

Most aquatic species in the watershed are non-native species, many of which are considered invasive. Like non-native terrestrial species, potential impacts to non-native aquatic species are not considered significant. As many of the potentially impacted species have been identified as invasive (meaning they are considered likely to cause economic or environmental harm or harm to human health), adverse impacts could be considered a benefit. However, given the scale of the project, any actual change in local populations is likely to be so low as to be insignificant.

Although not abundant, native aquatic species have been documented in all of the streams and canals in the watershed (including four gobiid species [o'opu nakea (*Awaous stamineus*), o'opu nopili (*Sicyopterus stimpsoni*), o'opu naniha (*Stenogobius hawaiiensis*), and o'opu akupa (*Eleotris sandwicensis*)], two shrimp species ['opae kala'ole (*Atyoida149ompletena*) and 'opae 'oeha'a (*Macrobrachium grandimanus*)] and a mollusk species [hapawai (*Neritina149ompletenea*)]. Construction of the project features would primarily not occur within the streams but would be adjacent to streams. Construction of the floodwall along the right descending bank of the Manoa-Palolo canal would require the placement of a rock bench within the Manoa-Palolo canal adjacent to the stream bank. The rock bench would be approximately 15 feet in width and would run parallel to the channel bank. Equipment and personnel needed to construct the floodwall would be staged on the rock bench which would be completely removed once construction of the floodwall is complete. In addition to the above floodwall, the construction of inlet and outlet structures associated with the Ala Wai Golf Course Detention Basin and the Ala Wai Canal floodwall could potentially require work within the streams/canal. Work is anticipated to occur mostly from shore, but for outlets below the water line a cofferdam would need to be installed to block of the construction area from the surrounding aquatic environment. The cofferdam would be the minimum size needed to access the area and complete the construction activities. The cofferdam would be completely removed once construction is complete. The placement of the rock bench and cofferdams, though, could have potential impacts to aquatic species such as injury, death, or possible entrainment. To minimize potential impacts to species, each inlet/outlet structure requiring a cofferdam would be dewatered prior to construction, with proper fish exclusion protocols and other standard BMPs implemented, such that construction-related impacts to native aquatic species are expected to be less than significant. Recommended protocols and BMPs are expected to include the following:

- The extent and duration of instream work would be minimized to the extent possible.
- Construction activities within the stream channels would be limited to low-flow conditions. In addition to minimizing the extent of dewatering required, this would also serve to minimize the potential to disrupt migration of native species.
- Proper dewatering techniques would be implemented, as needed. For example, sandbags or a cofferdam would be used to isolate the work area. If needed, a pump would be used to dewater the construction area within the cofferdam. The pump would be properly screened to preclude entrapment of fish, and the area would be adequately inspected to ensure no fish are stranded.

As part of the long-term project operation, O&M activities would be required to keep the flood risk management structures in proper working order; in-stream O&M activities would include periodic sediment/debris removal from inlet and outlet structures. This above-listed BMPs would be implemented (as appropriate), such that impacts are expected to be less than significant.

In addition to the direct impacts to aquatic fauna, the project would also impact aquatic habitat, which could indirectly affect native aquatic species. The primary direct impact to aquatic habitat

is during construction of the project. Construction of the Makiki Park Detention Basin, Manoa Valley Park Detention Basin, Koali Road Floodwall, and the Ala Wai Golf Course Detention Basin include inlet and outlet structures. The inlet structures intercept water and divert it either into a detention basin for storage or discharge interior drainage into a waterway on the other side of a floodwall. The outlet structures discharge stored water from a detention basin back into a waterway. Where these structures connect to the waterway, aquatic habitat could be impacted while construction is occurring. The project would incorporate BMPs to minimize erosion and turbidity into adjacent waterways while the inlet and outlet structures are being constructed. The design of the inlet and outlet structures would minimize the potential for scouring and erosion around the structures long-term. In addition, water discharged from the detention basin outlet structures has the potential to be less turbid as some sediment may fall out during storage. Therefore, less than significant impacts to aquatic habitat are anticipated.

Federal Listed Species and Species of Special Concern
Several ESA-listed species have the potential to be affected by the project; these are Hawaiian hoary bat, seabirds (i.e., band-rumped storm-petrel and Newell's Townsend's shearwater), and Hawaiian waterbirds (i.e., Hawaiian duck, Hawaiian gallinule, Hawaiian coot, Hawaiian petrel, and Hawaiian stilt). Potential impacts to these species are summarized below, with further detail provided in the Biological Assessment (Appendix K). The alternative action area does not contain critical habitat. ESA compliance is discussed in Section 6.1.

Hawaiian hoary bat (ESA status – Endangered): Should they occur, Hawaiian hoary bats could be directly or indirectly impacted by the project. Direct effects could include mortality or other forms of take (e.g., harm or harassment) to individual bats as a result of heavy equipment used for clearing and grubbing of the construction sites and construction of the flood risk management structures. The use of heavy equipment would also generate noise, which could disrupt bats that are present within the alternative action area. To avoid and minimize the potential for these impacts, vegetation clearing for the project would be performed during times of the year when Hawaiian hoary bats are not expected to be breeding to avoid potential for harm or disruption of juvenile bats that are unable to fly; specifically trees greater than 15 feet in height would not be cleared between June 1 and September 15. In addition, all construction activities would be scheduled to occur during daytime hours, thus avoiding potential bat foraging activities, which typically occur in the evening hours.

Other effects could include permanent loss or temporary impacts to habitat. However, given the amount of habitat available through the upper Ala Wai watershed, tree clearing within the alternative action area is not expected to measurable decrease the amount of forest available to the local population of bats for roosting. In addition, on Oahu roost trees are plentiful and are not expected to be a limiting factor for the species. The forest habitat in the upper portions of the Ala Wai watershed is homogenous and does not vary significantly in composition or structure between adjacent patches. For these reasons, it is expected that any bats displaced by the clearing would readily find alternate roost sites in surrounding undisturbed forest.

With the implementation of seasonal restrictions for tree trimming/clearing and enforcement of construction hours, impacts to the Hawaiian hoary bat are expected to be insignificant, such that the project may affect, but is not likely to adversely affect the species.

Seabirds (i.e., band-rumped storm petrel [ESA status – Endangered], Hawaiian petrel [ESA status – Endangered], and Newell's Townsend's shearwater [ESA status – Endangered]): No direct effects due to implementation of the project are expected to sea bird species since the proposed alternative action area does not provide suitable nesting habitat.

Therefore, there would be no direct impacts to sea bird nesting habitat. During construction of the proposed project, artificial lighting could be used during pre-dawn and pre-dusk hours within staging areas. Seabirds show a strong attraction to light sources, including artificial lights. Artificial lights can act as an attractant causing disorientation, confusion, and eventual grounding. The effects of artificial lights lead to a condition known as fallout, where fledgling young and adults are grounded and unable to regain flight, making them vulnerable to depredation or dehydration. Avoidance and minimization measures regarding artificial lighting would be implemented to reduce potential indirect impacts to seabirds that may be flying over the proposed alternative footprint. Given the above, coupled with the nature of activities proposed in the alternative footprint, impacts to seabirds are expected to be insignificant, such that the project may affect, but is not likely to adversely affect seabird species.

Hawaiian Waterbirds (i.e., Hawaiian duck (ESA status – Endangered), Hawaiian common gallinule [ESA status – Endangered], Hawaiian coot [ESA status – Endangered], and Hawaiian stilt [ESA status – Endangered]): The extent and quality of potentially suitable habitat within the proposed alternative footprint is very limited and is likely to only be used as resting habitat for Hawaiian waterbird species. In the unlikely event that Hawaiian waterbird species are present within the proposed alternative footprint, it is expected that they would readily disperse to nearby areas with higher quality habitat (e.g., Pearl Harbor National Wildlife Refuge) in response to disturbance; as such, the potential effects of the proposed project are expected to be limited to temporary construction-related disturbance (e.g., noise). Injury or mortality of Hawaiian waterbird species (or their nests) is not expected.

Areas of potentially suitable wetland habitat may be temporarily unavailable during construction (due to increased levels of disturbance), but sufficient habitat is expected to be available in nearby areas (e.g., Pearl Harbor National Wildlife Refuge). Following construction, the extent and quality of habitat is expected to be the same as the existing condition. During large-scale flood events, the detention basins would be inundated for short periods of time (i.e., about 1 day for Manoa Valley and Makiki Park District detention basins and about 2 days for the Ala Wai Golf Course detention basin), which could temporarily increase the extent of potential habitat. Although increased habitat may be viewed as a benefit, in heavily urbanized areas (such as the Ala Wai watershed), it can also create an attractive nuisance for waterbird species. Specifically, areas of increased habitat may attract waterbirds, which are then vulnerable to predator species that are prevalent in an urban environment (e.g., feral cats, mongoose). However, given the low probability of species occurrence and the infrequent recurrence and short-term duration of flooding, these conditions are not expected to significantly affect Hawaiian waterbirds. Based on the minimal extent and quality of suitable habitat, there is a low probability of species occurrence in the proposed alternative footprint. Given the above, coupled with the nature of activities proposed, impacts to Hawaiian waterbirds are expected to be insignificant, such that the proposed project may affect, but is not likely to adversely affect Hawaiian waterbird species.

Essential Fish Habitat

Pursuant to the Magnuson-Stevens Act, an adverse effect is defined as any impact that reduces quality and/or quantity of EFH; this includes direct or indirect physical, chemical, or biological alterations of the waters or substrate and loss of, or injury to species and their habitat, and other ecosystem components.

As described in Section 3.4.5, no portion of the proposed alternative footprint has been designated as EFH, such that the proposed project is not expected to directly affect the quality and/or quantity of EFH. The nearshore waters downstream from the Ala Wai Canal (i.e., Ala Wai Small Boat Harbor, Mamala Bay, etc.) include EFH for various lifestages of bottomfish,

seamount groundfish, pelagics, and crustaceans. In general, conditions that could indirectly affect EFH include increased delivery of sediment and associated contaminants, which could smother bottom substrate and degrade water quality. However, as described in Section 3.3.4, the proposed project is not expected to result in significant water quality impacts, either within the streams or nearshore waters (including EFH). Rather, it is possible that some degree of benefit could be realized over the long-term through the capture and removal of sediment from the three proposed detention basins. As such, the proposed project is not expected to adversely affect EFH, either directly or indirectly.

Refer to Appendix K for the EFH analysis and the USACE's determination that the proposed project would have no adverse effect on EFH.

Conservation Plan(s)
There are no HCPs in place within the proposed alternative footprint, therefore, the project would have no direct or indirect effects on implemented HCPs.

Alternative 2B

Less than Significant Impact with Environmental Commitments Incorporated:

Plant Communities
Construction of Alternative 2B would involve clearing and trimming of vegetation within the construction limits (including any associated staging and access roads) at each of the structural measure sites. Of this area, vegetation would be permanently displaced with the construction of the Kanaha floodwall, Woodlawn Drive floodwall, Koali Road floodwall, Kaimuki High School floodwall, and the Ala Wai Canal floodwall (including the Ala Wai Golf Course). Vegetation would also be permanently displaced with the construction of the road closure structures associated with the floodwalls and inlets/outlets. Vegetation within the Makiki District Park detention basin would be temporarily displaced during construction. Excavation of the park district detention basin would temporarily impact turf grass. Construction of the earthen berms around the park district detention basin would also temporarily impact turf grass. Once construction is completed, the earthen berms would be reseeded with native grass species (where practicable). The long-term operation and maintenance of the structural features would need to be maintained in accordance with Corps of Engineers Engineering Pamphlet (EP) 1110-2-18. EP 1110-2-18 requires that a minimum 15-feet down slope of a floodwall, including earthen berms, needs to be a vegetation free zone (VFZ). The VFZ applies to all vegetation except for grasses for the purpose of erosion control.

The approximate areas that would be impacted are summarized in Table .

Table 39: Summary of Disturbance Acres for Alternative 2B Measures.

Structural Feature	Total Construction Area (acres)	Permanent Footprint (acres)	Vegetation Management Area for O&M (acres)	Inundation Area During Flood (acres)
Makiki District Park Detention Basin	8.46	6.77	6.77	2.26
Kanaha Floodwall	3.64	2.03	2.03	NA
Woodlawn Drive Floodwall	2.40	1.27	1.27	NA

Structural Feature	Total Construction Area (acres)	Permanent Footprint (acres)	Vegetation Management Area for O&M (acres)	Inundation Area During Flood (acres)
Koali Road Floodwall	5.00	2.47	2.47	NA
Kaimuki High School Floodwall	6.66	15.76	15.76	12.59
Ala Wai Canal Floodwall	43.82	180.31	180.31	156.03
TOTAL	**69.98**	**208.61**	**208.61**	**170.88**

The vegetation that would be impacted is predominantly comprised of non-native species, many of which are considered invasive. Native species present within the measure sites are commonly occurring throughout Hawaii, no federally listed plant species are expected to be present.

In general, impact to non-native vegetation is not considered to be significant. However, some of this vegetation may provide habitat for aquatic and other wildlife species within the watershed, such that impacts to the vegetation could affect the wildlife species. Specifically, riparian vegetation, even if non-native and/or invasive, still provides shade and cover that contributes to habitat quality for native stream species. Similarly, non-native tree species may still provide habitat for native birds or bats.

Although impacts to vegetation are generally expected to be less than significant, construction of the project could affect a few concentrations of native species. Specifically, this includes a series of niu and milo trees planted along the Ala Wai Canal. To the extent, these trees would be avoided during construction. Where impacts cannot be avoided, the individual trees would either be replaced in-kind following construction or relocated to a suitable location near the alternative footprint. The exact location and total numbers of trees to be affected and replaced/relocated would be determined as part of pre-construction surveys.

Following construction, long-term operation and maintenance of the project would require ongoing vegetation management, including clearing and trimming in select locations. Specifically, a 15-foot-wide buffer around the perimeter of the detention structures and floodwalls would be revegetated with a suitable grass species; vegetation management would involve mowing the grass and removing any woody vegetation. Vegetation along the access roads would also be periodically trimmed, as needed to maintain adequate clearance for access. The estimated area in which vegetation will be maintained is provided in Table 39. As the areas to be maintained are within the construction limits, they will have been previously disturbed as part of the construction (and revegetated, as appropriate); no sensitive species are expected to colonize these areas. Therefore, maintenance of these areas is not expected to result in more than minimal vegetation-related impacts.

During flood conditions, the Makiki Park District detention basin would occasionally be used to store flood waters, and vegetation within the inundation zone could be temporarily impacted by the floodwaters. The approximate extent of vegetated areas that would be inundated (based on the 20-year event) is summarized in Table 39. The inundation period would be relatively short (in general, about 24 hours for the Makiki District Park detention basin). Given the short duration

of inundation, coupled with the lack of sensitive vegetation resources in this area, operation of the detention basin is not expected to significantly affect vegetation resources.

Invasive plants, such as Java plum, strawberry guava, swamp mahogany, and albizia, are widespread within the alternative action area. Given the prevalence of these species, implementation of the project is not expected to result in a significant increase in the distribution or spread of invasive plant species within the sites. However, construction of the project could potentially result in the introduction of new invasive plant species within the site. However, construction of the project could potentially result in the introduction of new invasive species to the construction site. To minimize this potential impact, the following BMPs would be implemented:

- All construction equipment, materials, and vehicles arriving from outside of the island of Oahu would be washed and/or visually inspected (as appropriate) for excessive debris, plant materials, and invasive or harmful non-native species before transportation to the construction site; import of materials that are known or likely to contain seeds or propagules of invasive species that would be prohibited.
- Offsite sources of vegetation materials (such as seed mixes) would be certified as weed-free or inspected before transport to the alternative footprint.
- All areas that are hydroseeded would be monitored for six months after hydroseeding to identify invasive plants that establish from seeds inadvertently introduced as part of the seed mix; all invasive plants identified within the hydroseed areas would be removed.
- At the end of the construction period, areas impacted by construction of the project would be surveyed to confirm that no problematic and/or invasive species has been introduced and become established. Appropriate remedial actions would be undertaken to facilitate containment or eradication of the target species as soon as reasonably possible.

Based on the prevalence of non-native species and lack of sensitive vegetation resources, coupled with the mitigation measure to replace/relocate native species and minimize the introduction of invasive species, impacts to vegetative resources are expected to be less than significant.

Wildlife Communities

Wildlife resources that occur (or could potentially occur) within the watershed include a suite of native aquatic and terrestrial species, some of which are federally and state listed as endangered. Impacts to these resources are specifically addressed in the subsections below. In general, other wildlife is comprised of non-native and/or invasive species, although a limited number of non-listed native species could occur (e.g., native birds). Potential effects to non-listed native terrestrial species could include both direct impacts (e.g., disturbance, collision with project vehicles, etc.) and indirect impacts associated with habitat loss. However, non-listed native terrestrial species that occur in the alternative action area are generally common and widespread on Oahu, such that direct impacts would not significantly reduce the local population. The proposed project would reduce the amount of habitat available for these species, which could result in the displacement of some individuals. However, the amount of affected habitat represents a very small part of the total range available to each species. Consequently, impacts to non-listed terrestrial species are not considered significant.

Potential impacts to non-native wildlife species are not considered significant. Many of the potentially impacted species have been identified as invasive, which are species that are

considered likely to cause economic or environmental harm or harm to human health (EO 13112). For example, feral pigs are generally considered to be a threat to ecosystems as they often consume or trample native flora and fauna, accelerate erosion, alter soil properties, and promote the invasion of non-native plants (Stone et al., 1992; Courchamp et al., 2003). Invasive bird species aggressively chase and outcompete native species for food and space; they also spread the seeds of invasive plant species. As such, adverse impacts to invasive species could be considered a positive effect, although given the scale of the project, any change in local populations is likely to be so low as to be insignificant.

Aquatic Communities

Most aquatic species in the watershed are non-native species, many of which are considered invasive. Like non-native terrestrial species, potential impacts to non-native aquatic species are not considered significant. As many of the potentially impacted species have been identified as invasive (meaning they are considered likely to cause economic or environmental harm or harm to human health), adverse impacts could be considered a benefit. However, given the scale of the project, any actual change in local populations is likely to be so low as to be insignificant.

Although not abundant, native aquatic species have been documented in all of the streams and canals in the watershed (including four gobiid species [o'opu nakea (*Awaous stamineus*), o'opu nopili (*Sicyopterus stimpsoni*), o'opu naniha (*Stenogobius hawaiiensis*), and o'opu akupa (*Eleotris sandwicensis*)], two shrimp species ['opae kala'ole (*Atyoida155ompletena*) and 'opae 'oeha'a (*Macrobrachium grandimanus*)] and a mollusk species [hapawai (*Neritina155ompletenea*)]. Construction of the project features would primarily not occur within the streams but would be adjacent to streams. Construction of the floodwall along the right descending bank of the Manoa-Palolo canal would require the placement of a rock bench within the Manoa-Palolo canal adjacent to the stream bank. The rock bench would be approximately 15 feet in width and would run parallel to the channel bank. Equipment and personnel needed to construct the floodwall would be staged on the rock bench which would be completely removed once construction of the floodwall is complete. In addition to the above floodwall, the construction of inlet and outlet structures associated with the Ala Wai Canal floodwall could potentially require work within the canal. Work is anticipated to occur mostly from shore, but for outlets below the water line a cofferdam would need to be installed to block of the construction area from the surrounding aquatic environment. The cofferdam would be the minimum size needed to access the area and complete the construction activities. The cofferdam would be completely removed once construction is complete. The placement of the rock bench and cofferdams, though, could have potential impacts to aquatic species such as injury, death, or possible entrainment. To minimize potential impacts to species, each inlet/outlet structure requiring a cofferdam would be dewatered prior to construction, with proper fish exclusion protocols and other standard BMPs implemented, such that construction-related impacts to native aquatic species are expected to be less than significant. Recommended protocols and BMPs are expected to include the following:

- The extent and duration of instream work would be minimized to the extent possible.
- Construction activities within the stream channels would be limited to low-flow conditions. In addition to minimizing the extent of dewatering required, this would also serve to minimize the potential to disrupt migration of native species.
- Proper dewatering techniques would be implemented, as needed. For example, sand bags or a cofferdam would be used to isolate the work area. If needed, a pump would be used to dewater the construction area within the cofferdam. The pump would be properly screened to preclude entrapment of fish, and the area would be adequately inspected to ensure no fish are stranded.

As part of the long-term project operation, O&M activities would be required to keep the flood risk management structures in proper working order; in-stream O&M activities would include periodic sediment/debris removal from inlet and outlet structures. The above-listed BMPs would be implemented (as appropriate), such that impacts are expected to be less than significant.

In addition to the direct impacts to aquatic fauna, the project would also impact aquatic habitat, which could indirectly affect native aquatic species. The primary direct impact to aquatic habitat is during construction of the project. Construction of the Makiki Park Detention Basin, Koali Road Floodwall, and the Ala Wai Canal floodwall include inlet and outlet structures. The inlet structures intercept water and divert it either into a detention basin for storage or discharge interior drainage into a waterway on the other side of a floodwall. The outlet structures discharge stored water from a detention basin back into a waterway. Where these structures connect to the waterway, aquatic habitat could be impacted while construction is occurring. The project would incorporate BMPs to minimize erosion and turbidity into adjacent waterways while the inlet and outlet structures are being constructed. The design of the inlet and outlet structures would minimize the potential for scouring and erosion around the structures long-term. In addition, water discharged from the detention basin outlet structures has the potential to be less turbid as some sediment may fall out during storage. Therefore, less than significant impacts to aquatic habitat are anticipated.

Federal Listed Species and Species of Special Concern

Several ESA-listed species have the potential to be affected by the project; these are Hawaiian hoary bat, seabirds (i.e., band-rumped storm-petrel and Newell's Townsend's shearwater), Hawaiian waterbirds (i.e., Hawaiian duck, Hawaiian gallinule, Hawaiian coot, Hawaiian petrel, and Hawaiian stilt), Hawaiian monk seal, and sea turtles (i.e., green sea turtle and hawksbill sea turtle). Potential impacts to these species are summarized below, with further detail provided in the Biological Assessment (Appendix K). The project area does not contain critical habitat. ESA compliance is discussed in Section 6.1.

Hawaiian hoary bat (ESA status – Endangered): Should they occur, Hawaiian hoary bats could be directly or indirectly impacted by the project. Direct effects could include mortality or other forms of take (e.g., harm or harassment) to individual bats because of heavy equipment used for clearing and grubbing of the construction sites and construction of the flood risk management structures. The use of heavy equipment would also generate noise, which could disrupt bats that are present within the alternative action area. To avoid and minimize the potential for these impacts, vegetation clearing for the project would be performed during times of the year when Hawaiian hoary bats are not expected to be breeding to avoid potential for harm or disruption of juvenile bats that are unable to fly; specifically trees greater than 15 feet in height would not be cleared between June 1 and September 15. In addition, all construction activities would be scheduled to occur during daytime hours, thus avoiding potential bat foraging activities, which typically occur in the evening hours.

Other effects could include permanent loss or temporary impacts to habitat. However, given the amount of habitat available through the upper Ala Wai watershed, tree clearing within the alternative footprint is not expected to measurable decrease the amount of forest available to the local population of bats for roosting. In addition, on Oahu roost trees are plentiful and are not expected to be a limiting factor for the species. The forest habitat in the upper portions of the Ala Wai watershed is homogenous and does not vary significantly in composition or structure between adjacent patches. For these reasons, it is expected that any bats displaced by the clearing would readily find alternate roost sites in surrounding undisturbed forest.

With the implementation of seasonal restrictions for tree trimming/clearing and enforcement of construction hours, impacts to the Hawaiian hoary bat are expected to be insignificant, such that the project may affect, but is not likely to adversely affect the species.

Seabirds (i.e., band-rumped storm petrel [ESA status – Endangered], Hawaiian petrel [ESA status – Endangered], and Newell's Townsend's shearwater [ESA status – Endangered]): No direct effects due to implementation of the project are expected to sea bird species since the proposed alternative action area does not provide suitable nesting habitat. Therefore, there would be no direct impacts to sea bird nesting habitat. During construction of the proposed project, artificial lighting could be used during pre-dawn and pre-dusk hours within staging areas. Seabirds show a strong attraction to light sources, including artificial lights. Artificial lights can act as an attractant causing disorientation, confusion, and eventual grounding. The effects of artificial lights lead to a condition known as fallout, where fledgling young and adults are grounded and unable to regain flight, making them vulnerable to depredation or dehydration. Avoidance and minimization measures regarding artificial lighting would be implemented to reduce potential indirect impacts to seabirds that may be flying over the proposed alternative footprint. Given the above, coupled with the nature of activities proposed in the alternative footprint, impacts to seabirds are expected to be insignificant, such that the project may affect, but is not likely to adversely affect seabird species.

Hawaiian Waterbirds (i.e., Hawaiian duck (ESA status – Endangered), Hawaiian common gallinule [ESA status – Endangered], Hawaiian coot [ESA status – Endangered], and Hawaiian stilt [ESA status – Endangered]): The extent and quality of potentially suitable habitat within the proposed alternative action area is very limited and is likely to only be used as resting habitat for Hawaiian waterbird species. In the unlikely event that Hawaiian waterbird species are present within the proposed alternative action area, it is expected that they would readily disperse to nearby areas with higher quality habitat (e.g., Pearl Harbor National Wildlife Refuge) in response to disturbance; as such, the potential effects of the proposed project are expected to be limited to temporary construction-related disturbance (e.g., noise). Injury or mortality of Hawaiian waterbird species (or their nests) is not expected.

Areas of potentially suitable wetland habitat may be temporarily unavailable during construction (due to increased levels of disturbance), but sufficient habitat is expected to be available in nearby areas (e.g., Pearl Harbor National Wildlife Refuge). Following construction, the extent and quality of habitat is expected to be the same as the existing condition. During large-scale flood events, the detention basins would be inundated for short periods of time (i.e., about 1 day for Manoa Valley and Makiki Park District detention basins and about 2 days for the Ala Wai Golf Course detention basin), which could temporarily increase the extent of potential habitat. Although increased habitat may be viewed as a benefit, in heavily urbanized areas (such as the Ala Wai watershed), it can also create an attractive nuisance for waterbird species. Specifically, areas of increased habitat may attract waterbirds, which are then vulnerable to predator species that are prevalent in an urban environment (e.g., feral cats, mongoose). However, given the low probability of species occurrence and the infrequent recurrence and short-term duration of flooding, these conditions are not expected to significantly affect Hawaiian waterbirds. Based on the minimal extent and quality of suitable habitat, there is a low probability of species occurrence in the proposed alternative action area. Given the above, coupled with the nature of activities proposed, impacts to Hawaiian waterbirds are expected to be insignificant, such that the proposed project may affect, but is not likely to adversely affect Hawaiian waterbird species.

Hawaiian monk seal (ESA status – Endangered): Activities associated with the proposed action could reasonably be expected to interact directly or indirectly with Hawaiian monk seal through:

1. Collision with vessels;
2. Direct physical impact;
3. Disturbance from human activity and equipment operation;
4. Exposure to elevated noise levels;
5. Exposure to elevated turbidity;
6. Exposure to wastes and discharges; and
7. Loss of forage habitat.

Collision with vessels:

Activities associated with the proposed action do not include the use of vessels in nearshore marine waters or lower reaches of rivers and streams. All work is anticipated to occur from upland with equipment staged upland.

Direct physical impact:

Physical impact to Hawaiian monk seal is not expected to occur. At this time, all construction work would occur from upland with no construction equipment (i.e., push barge, vessel, etc.) anticipated to be present within the aquatic habitat. The exception is construction of the Ala Wai Canal floodwall which includes upgrading existing stormwater drainage outlets. Upgrades would potentially include increasing the size of the outlets and/or installing flap gates on the outlets. While some outlets would be accessible from upland and would not require in-water work, some of the outlets to be upgraded could be at water level or below water level. For outlets that cannot be upgraded from land only, minor in-water work would occur. In-water work would require the placement of a cofferdam around the work area. The placement of cofferdam materials could potentially physically impact Hawaiian monk seal should these animals be present when cofferdam materials strike the bottom. Potential injuries and their severity will depend on the animal's proximity to the bottom when struck, the angle of the strike, and the body part impacted, but may include cuts, bruises, broken bones, and amputations, any of which could result in the animal's death. Hawaiian monk seal could also be pinned to the bottom and drowned. To minimize potential physical impacts to Hawaiian monk seal during cofferdam material placement, avoidance and minimization measures listed further below in this section under environmental commitments would be implemented. Some of these avoidance and minimization measures require surveys for ESA-listed species in the area to occur prior to the start of each workday and prior to resumption of work following any break of more than one-half hour. They also require that all work be postponed or halted when motile ESA-listed marine species are within 164 feet of proposed work and resumption of activities should only occur after the animals have voluntarily left the area. These types of avoidance and minimization measures (refer to the environmental commitments listed further below in this section for the complete list) would minimize the potential physical impact to Hawaiian monk seal during the placement and removal of cofferdam material.

Disturbance from human activity and equipment operation:

Although construction of the floodwalls would occur upland, work would occur near marine habitat where ESA-listed marine species may be directly exposed to project-related activity. Hawaiian monk seal may experience a startle reaction and resulting stress should they

encounter site preparation and construction activities. The reaction could range from one extreme where an animal calmly approaches and investigates the activity, to an opposite reaction of panicked flight, where an animal injures itself in an attempt to flee. However, marine mammals such as Hawaiian monk seal typically avoid human activity. Thus, the most likely effect of this interaction will be moderate level stress with a moderate to high energy avoidance behavior leading to the Hawaiian monk seal rapidly leaving the project footprint without injury.

Exposure to elevated noise levels:

Activities such as pile-driving may produce in-air and in-water sound levels capable of injury or adverse behavioral modifications for Hawaiian monk seal. Much of the construction for the proposed action would occur upland and adjacent to waterways, not within a waterway. For example, construction of the floodwalls along Manoa-Palolo Canal and the Ala Wai Canal would occur upland. In addition, most of the floodwalls being constructed do not include pile driving; the exception being the reach along the right-descending bank of the Manoa-Palolo Canal between Kapiolani Boulevard and Date Street. In this reach, the upland area is constricted to such a degree that a steel sheet pile wall (i.e., I-wall) would need to be installed in this location. A 15-foot-wide rock bench would be placed in-water along the right-descending bank of the Manoa-Palolo Canal parallel to the bank. Equipment for construction of the I-wall would be staged along this rock bench. Upon completion of the I-Wall, the rock bench would be permanently removed. Although equipment for constructing of the floodwall would be staged along the 15-foot-wide rock bench, inserting the steel sheet pile for the floodwall would be into the adjacent upland area. The method to be used would be push in place instead of impact pile driving. The push in place method pushes the steel sheet pile into the ground without an impact hammer or vibration. The operation, except for a crane engine (to hold the steel sheet pile) and the generator to power the machine for pushing in the pile, is almost silent. For reference, a crane and a generator typically produce airborne noise levels of 87 dBA at 50 feet from the source. Therefore, using the push in place method would reduce airborne noise levels typically associated with pile driving as well as in water noise levels. In addition, installation of pile would be upland where it is in the dry. Pile installation in the dry is typically a minimization measure designed to reduce the amount of sound that is transmitted through water. Although there is no method for calculating sound transmission loss through soil outside of the water, and then calculating the loss in water, it is assumed that transmission loss through soil is greater than what occurs in water or air due to the density of soil. Since pile installation would occur upland, this would be like pile driving occurring in the dry; therefore, installing the pile upland is expected to be effective at minimizing the effects of sound in adjacent aquatic habitat and protecting Hawaiian monk seal from potential noise-related impacts.

The floodwall along the Ala Wai Canal does not include the installation of steel sheet pile. Instead, floodwalls along the Ala Wai Canal would be either J-walls or L-walls on macropiles. The macropiles require the use of a drill rig and associated drilling equipment to create a hole to design depth. The drill rig and drilling of the macropile hole would likely create the most noise during construction of these types of floodwalls. However, like the pile installation along the reach of Manoa-Palolo Canal, drilling would occur upland which is effective at minimizing the effects of sound in the water. Although there is no method for calculating sound transmission loss through soil outside of the water, and then calculating the loss in water, it is assumed that transmission loss through soil is greater than what occurs in water or air due to the density of soil. Since drilling of the macropile holes would occur upland, this is expected to be effective at minimizing the effects of sound in adjacent aquatic habitat and protecting Hawaiian monk seal from potential noise-related impacts.

In addition to construction of floodwall, the Ala Wai Canal floodwall also includes upgrading existing stormwater drainage outlets. Upgrades would potentially include increasing the size of the outlets and/or installing flap gates on the outlets. While some outlets would be accessible from upland and would not require in-water work, some of the outlets to be upgraded could be at water level or below water level. For outlets that cannot be upgraded from land only, minor in-water work would occur. In-water work would require the placement of a cofferdam around the work area, pumping the work area within the cofferdam dry, performing the upgrades, and then removal of the cofferdam materials. The size of the cofferdam would be the minimum necessary to perform the upgrade work. Placement of the cofferdam and removal of the cofferdam would potentially expose Hawaiian monk seals to project-related activity. However, Hawaiian monk seals typically avoid human interaction, so exposure to the project-related activity detailed above would be infrequent and non-injurious. The presence of the cofferdam would allow work on the stormwater drainage structures to be completed in the dry. As stated previously, working in the dry is a minimization measure designed to reduce the amount of sound that is transmitted through the water. Therefore, upgrading existing stormwater outlet structures would occur in the dry which is expected to be effective at minimizing the effects of sound in adjacent aquatic habitat and protecting Hawaiian monk seal from potential noise-related impacts.

Exposure to elevated turbidity and sedimentation:

In-water construction activities have the potential to generate turbidity through disturbance of existing in-place substrates causing the resuspension of sediments into the water column, thereby raising ambient turbidity levels. Elevated turbidity levels over ambient turbidity levels would degrade ambient water quality within the construction footprint and immediate surrounding area. Elevated turbidity levels would be discrete, temporary, and are expected to naturally dissipate, restoring water quality to ambient levels with no anticipated permanent impact to water quality resulting from construction. Suspended sediments are expected to settle rather quickly upon completion of any in-water disturbances. Adverse impacts to the water column within the Ala Wai Canal due to construction related turbidity, are likely to be limited in both physical and temporal extent due to the lack of currents in the canal and use of avoidance and minimization measures listed further below in this section under environmental commitments. The Ala Wai Canal is generally subjected to low flow velocities from tidal influence which naturally and considerably limit the potential for turbidity plumes to be carried into adjacent habitats (i.e., Ala Wai Small Boat Harbor, nearshore marine habitat). Given that the Ala Wai Canal is subject to bouts of high turbidity during storm events under the existing condition, it is unlikely that temporary increases in turbidity from constructing/modifying existing drainage structures would have any measurable impact upon Hawaiian monk seal.

As described under environmental commitments, located further below in this section, USACE has proposed BMPs (e.g., silt curtains) to contain resuspended sediments in the immediate in-water work areas during construction/modification of drainage structures to avoid spreading project-related, degraded water quality impacts to surrounding waters. In addition, USACE would stipulate to the contractor that no in-water construction activities could occur during periods of heavy rainfall. This would minimize the potential compounding adverse water quality impacts resulting from in-water construction work in combination with high turbidity levels from the Manoa-Palolo Canal during a storm event. Additionally, USACE is seeking a water quality certification under Section 401 of the Clean Water Act from the State of Hawaii Department of Health, Clean Water Branch (DOH-CWB). To obtain such certification, all proposed actions would comply with State water quality standards and implement necessary and appropriate monitoring BMPs to curtail water quality impacts.

The operation of the project is passive161ompleter, components of the project when working as a system could cause adverse indirect impacts to marine habitat occupied by the Hawaiian monk seal due to water quality degradation. The project includes the construction of floodwalls primarily along the Ala Wai Canal (including Manoa-Palolo Canal). Floodwalls would increase the capacity of the Ala Wai Canal to hold more storm water as well as increase storm flow velocities in the canal. Increased storm flow velocities in the canal could in turn disturb and/or resuspend sediments in the water column creating a turbidity plume that could affect water quality in the canal, the Ala Wai Small Boat Harbor, and the nearshore marine environment. Changes to velocities within the Ala Wai Canal were modeled with project features constructed and are compared against velocities within the canal under existing conditions in Table 40. Although the project would result in increased velocities and likely a large turbidity plume during a storm event, it is important to note that increased velocities and turbidity plumes already occur under the existing condition during a storm event.

Table 40: Future Without Project and Future with Project Modeled Velocities at the 5%, 2%, and 1% AEP.

Ala Wai Canal Location	Existing Velocities at Different AEPs without Project			Predicted Velocities at Different AEPs with Project			Velocity Difference (+) increase (-) decrease		
	5% AEP	2% AEP	1% AEP	5% AEP	2% AEP	1% AEP	5% AEP	2% AEP	1% AEP

Currently, under existing conditions, high rainfall events disturb sediments in the upper reaches of the Ala Wai watershed and cause these sediments to become suspended in the water column. There are also three general areas in the Ala Wai Canal where previously suspended sediments have sedimented out and built up within the canal: Kalakaua Avenue Bridge, mouth of the Manoa-Palolo Canal, and the terminus of the Ala Wai Canal (Montgomery et al., 2009). These built-up sediments within the canal at these locations can become resuspended in the water column during a storm event due to increased water velocities within the canal. The combination of these suspended sediments in the water column cause turbidity plumes during storm events which can extend beyond the canal and degrade water quality within the nearshore marine environment. Predicting how far turbidity plumes could extend during a storm event is difficult and can in turn make it difficult to predict where impacts to the nearshore marine environment could occur. However, PacIOOS has developed a turbidity plume forecast model for the Ala Wai Canal allowing the tracking of potential turbidity levels and extent of turbidity plumes along the nearshore marine environment. As an example of how a turbidity plume might extend out of the Ala Wai Small Boat Harbor and into the nearshore marine environment, PacIOOS conducted a model run of a turbidity plume for a storm event that occurred December 25 through December 27, 2017, in the Honolulu area. Figure 23 shows selected time progressions of this storm's modeled turbidity plume.

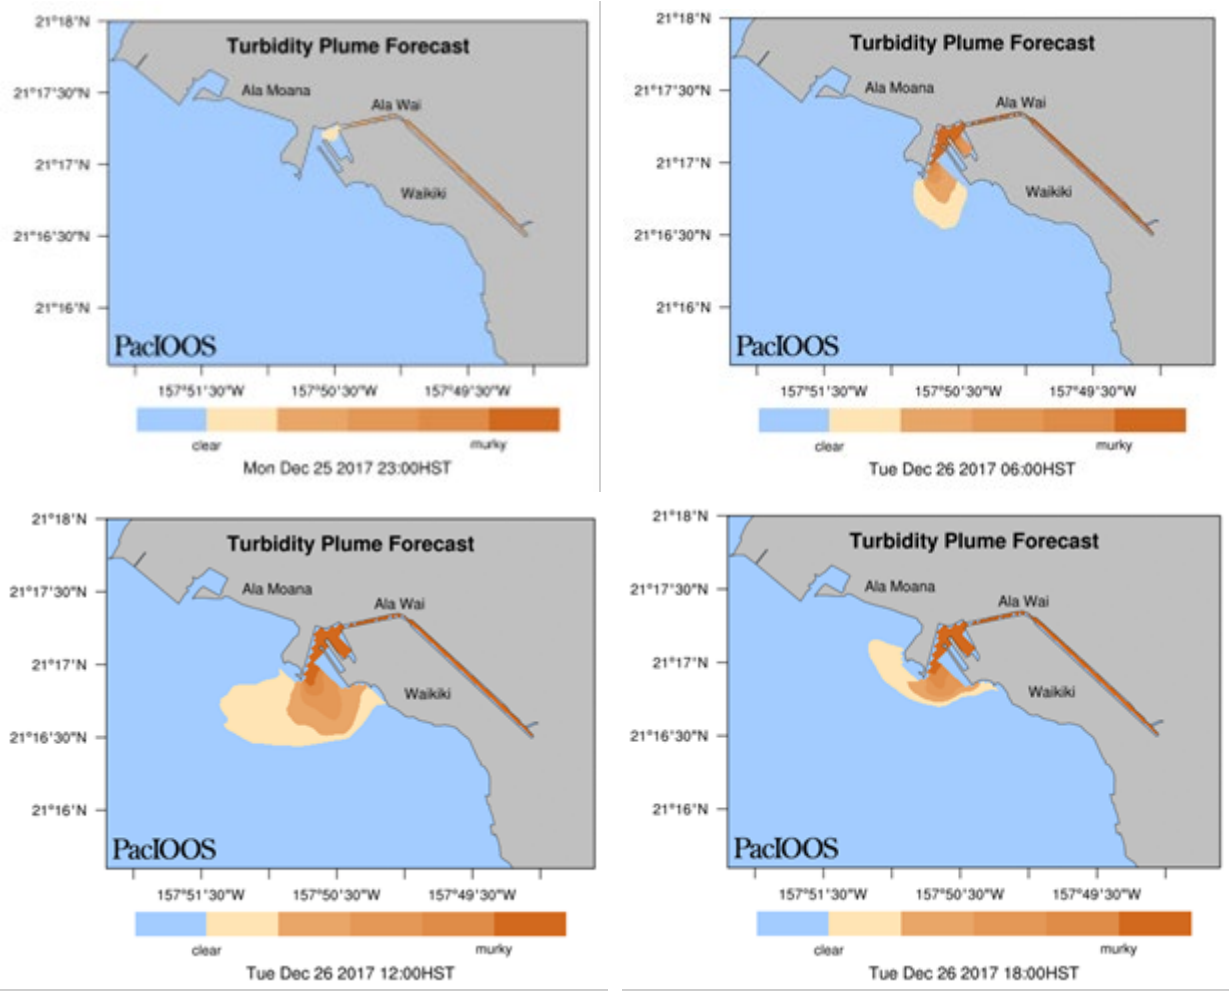

Figure 23: Modeled Turbidity Plume Forecast for December 25-27, 2017, High Rainfall Event.

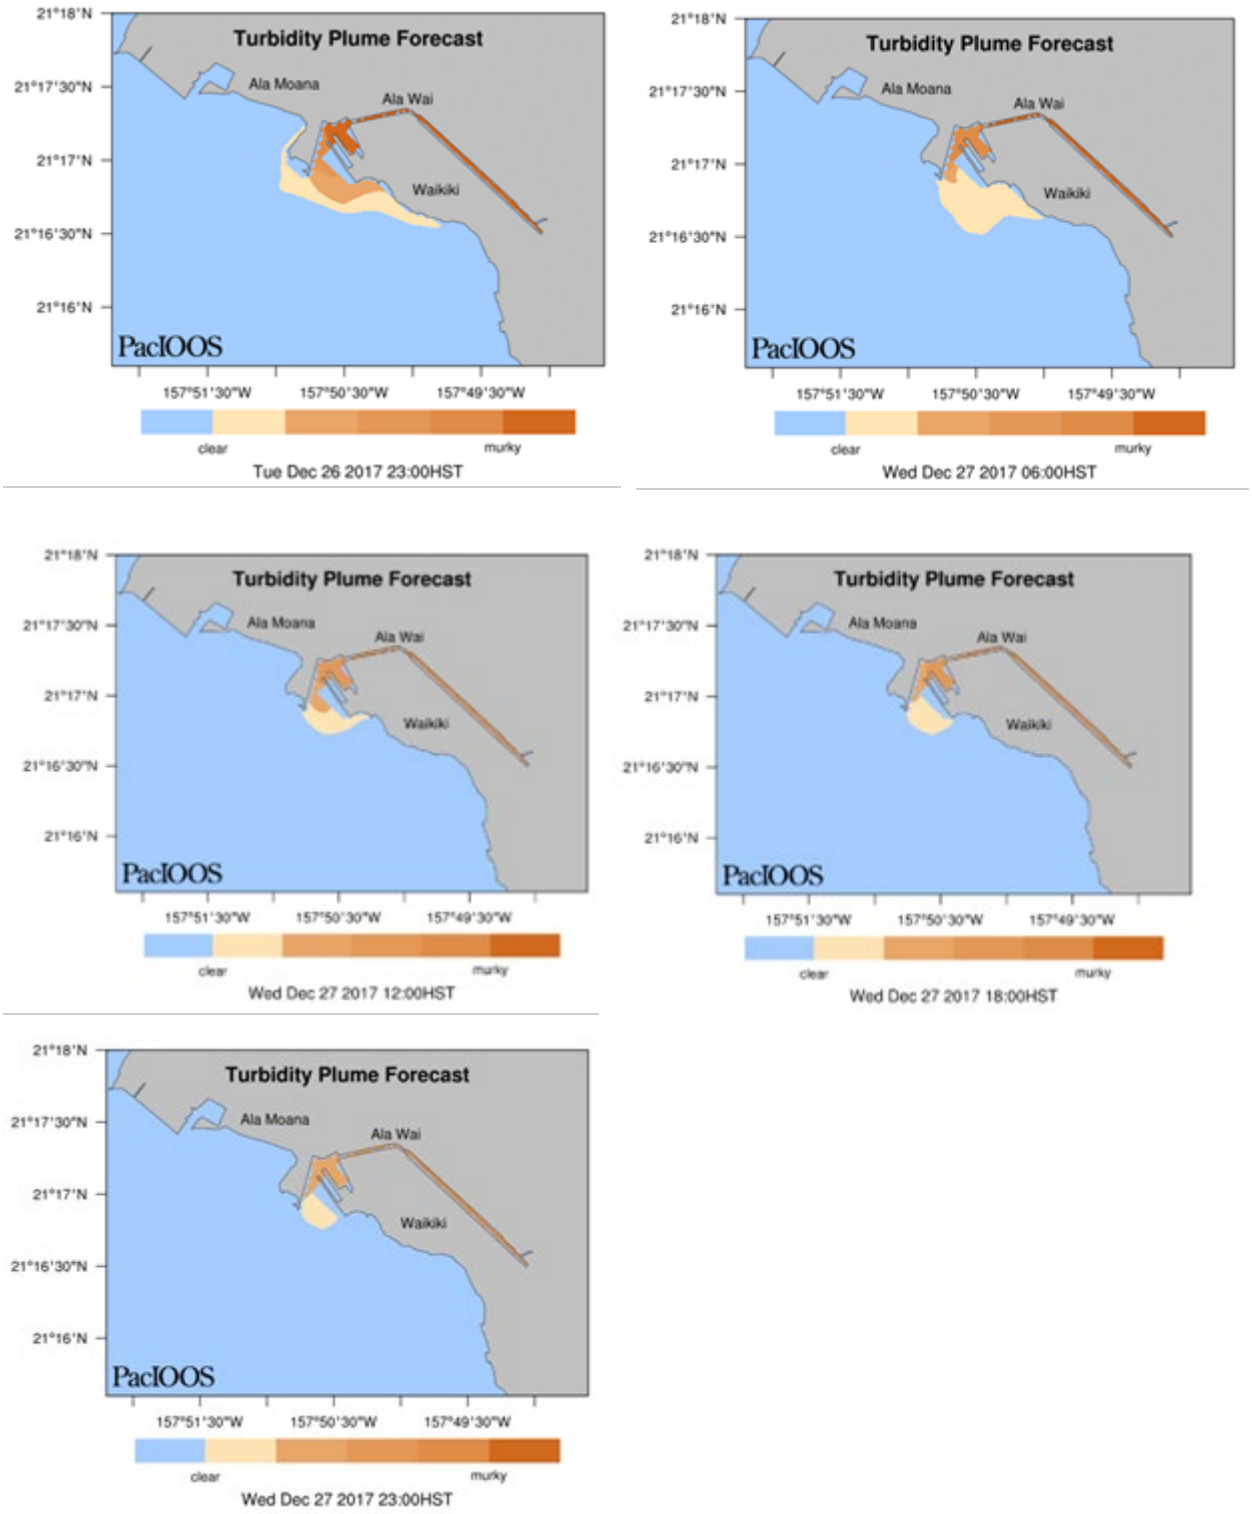

Figure 23, cont'd: Modeled Turbidity Plume Forecast for December 25-27, 2017, High Rainfall Event.

As seen in the above time progressions, at the beginning of the storm event (i.e., December 25; 23:00 HST) the Ala Wai Canal begins to experience high turbidity with low turbidity beginning to occur within the Ala Wai Small Boat Harbor. Following approximately 12 hours (i.e., December 26, 2017; 12:00 HST), high turbidity is experienced throughout Ala Wai Canal and Ala Wai Small Boat Harbor, while low to medium turbidity is beginning to occur along the reef flat area outside of Ala Wai Harbor and within the vicinity of the Atlantis Submarines harbor. Following the passage of another 12 hours (i.e., December 26, 2017; 23:00 HST), high turbidity continues to be experienced throughout the Ala Wai Canal, but high turbidity within the Ala Wai Boat Harbor is beginning to dissipate. Similarly, medium turbidity is still being experienced within the vicinity of the Atlantis Submarines Harbor and low turbidity is being experienced along the nearshore marine area (reef flat)—within the vicinity of the Sheraton Hotel on Waikiki. Following the passage of another 6 hours (i.e., December 27, 201; 06:00 HST), the turbidity plume begins to dissipate along the nearshore marine area, although low turbidity is still being experienced. Turbidity within the Ala Wai Boat Harbor has also begun to dissipate currently with moderate turbidity occurring in the harbor. Over the course of the following 18 hours, from 12:00 HST to 23:00 HST on December 27, 2017, the turbidity plume further dissipates, although low/medium turbidity is still being experienced within the Ala Wai Boat Harbor and the harbor channel. In addition, the Ala Wai Canal is experiencing medium turbidity still after approximately 48 hours has passed from the beginning of the storm event. The above details a potential turbidity plume under the future without project condition. This means that even under the future without project condition, marine habitat located within Ala Wai Harbor generally experiences high turbidity during a storm event while marine habitat located outside the Ala Wai Boat Harbor and along Waikiki Beach experiences medium to low turbidity during a storm event.

During a storm event under the future without project condition, marine habitat in the harbor (Ala Wai Small Boat Harbor and Atlantis Submarines Harbor), reef flat (adjacent to Ala Wai Small Boat Harbor), reef crest (near Ala Wai Small Boat Harbor), fore reef (near Ala Wai Small Boat Harbor), and bank/shelf (near Ala Wai Small Boat Harbor) zones experiences medium to high turbidity for approximately 24 hours (depending on the size of the storm event) before turbidity begins to dissipate. Low turbidity during this same time occurs in the shoreline intertidal and reef flat zones between the Atlantis Submarines Harbor and the Sheraton Hotel in Waikiki. Between approximately 24 and 48 hours (depending on the size of the storm event) following a storm event, turbidity within the harbor zone has been reduced to medium levels while turbidity along shoreline intertidal, reef flat, reef crest, fore reef, and bank/shelf zones has been reduced to low or clear levels.

Under the proposed project, turbidity plumes occurring during a storm event could carry higher sediment and nutrient concentrations and take additional time to dissipate upon reaching the nearshore marine environment. Therefore, medium to high turbidity levels could be experienced at the harbor, reef flat, reef crest, fore reef, and bank/shelf zones sooner than under the without project condition. Turbidity plumes extending into the nearshore marine environment may also take longer than approximately 24 hours for dissipation to begin. Elevated turbidity and sedimentation may impact Hawaiian monk seal. However, given that Hawaiian monk seal breathe air instead of water, increased turbidity should not adversely affect their respiration or other biological function.

Although BMPs are not defined for operation of the proposed project, the project does include a detention basin at the Ala Wai Golf Course that would collect storm water runoff from the Manoa-Palolo Canal, detain the runoff, and slowly release the runoff back into the Ala Wai Canal. The operation of the detention basin in conjunction with the floodwalls could minimize potential indirect impacts to marine habitat utilized by Hawaiian monk seal from acceleration of

the delivery of storm water runoff to the nearshore marine environment and the quality of storm water runoff reaching the nearshore marine environment. This is because storm water runoff from the Manoa-Palolo canal would be held within the detention basin for up to two days providing time for some sediments entrained within the water column to settle out in the detention basin. After approximately two days, the detained storm water runoff would begin to slowly be released back into the Ala Wai Canal. Sediment retained in the detention basin would then be collected and disposed of at an appropriate facility. With the operation of the detention basin, a negligible or no change to the sediment/nutrient concentration of the storm water runoff reaching the nearshore marine environment could occur. Most of the sediment containing excess nutrients and legacy contaminants comes from the Manoa and Palolo streams which feed into the Manoa-Palolo Canal. Therefore, the operation of the detention basin—which would hold storm water runoff from these streams during a storm event and provide time for sedimentation to occur—has the potential to avoid or minimize the possible impact of the proposed project on increased nutrient and sediment loading to the nearshore marine environment. The operation of the detention basin could also help avoid and minimize the potential impact of the proposed project on accelerated discharge of freshwater to the nearshore marine environment.

Exposure to wastes and discharges:

Although construction of the proposed action primarily occurs upland, construction activities are often located adjacent to the aquatic environment. Therefore, construction waste may end up in the aquatic environment if not properly disposed of. Construction wastes may include plastic trash and bags that may be ingested and cause digestive blockage or suffocation, or if large enough, along with discarded sections of ropes and lines, may entangle Hawaiian monk seal. Equipment spills and discharges likely consist of hydrocarbon-based chemicals such as fuel oils, gasoline, lubricants, hydraulic fluids, and other toxicants, which could expose Hawaiian monk seal to toxic chemicals. Depending on the chemicals and their concentration, exposure could result in a range of effects, from avoidance of an area to death. Local and Federal regulations prohibit the intentional discharge of toxic wastes and plastics into the marine environment. In addition, BMPs listed under environmental commitments located further below in this section include measures intended to prevent or reduce exposure of Hawaiian monk seal to wastes and discharges in the marine environment.

Loss of forage habitat:

Short-term, the loss of forage habitat could occur with the upgrading/modification of stormwater drainage structures which has the potential to be in habitat where Hawaiian monk seal may forage. The upgrading/modification of drainage structures includes the temporary placement of cofferdam materials within the Ala Wai Canal which may impact forage species through damage or destruction. At the level of the individual, the loss of significant levels of available forage may lead to lower growth rates, reduced fitness, reduced reproductive success, and potential death by starvation. At the population level, significantly reduced forage opportunities may eventually cause local extirpation through the death or emigration of members of that population.

The upgrading and/or modification of stormwater drainage structures would occur from upland if the structure is located above the water level of the canal. If the stormwater drainage structure is located at water level or below water level a cofferdam would need to be constructed so that upgrading and/or modification of the drainage structure could occur in the dry. The placement of cofferdam material would occupy the smallest footprint possible, therefore, limited in-water substrate disturbance is anticipated to occur. Once upgrading/modification of the drainage structure is complete the cofferdam would be removed in its entirety. Therefore, the loss of

potential forage habitat located within the cofferdam footprint would be temporary because epibenthic life would likely re-colonize the area once the structure is removed.

Long-term, the operation of the proposed action could cause sediment mobilization that has the potential to smother forage resources. An increase in suspended sediments during a storm event, above that experienced under the future without project condition, would likely result in increased deposition rates within the canal and nearshore marine areas. According to the Ala Wai Canal Watershed Water Quality Improvement Project (City and County of Honolulu, 1998), sedimentation in the Ala Wai Canal occurs at the rate of about 10,300 CY per year. Sedimentation is also prevalent in the Manoa-Palolo Canal which receives the first flush from storm waters. Increased sedimentation in nearshore marine waters could smother Hawaiian monk seal foraging habitat. Although the proposed project is expected to potentially increase sediment delivery to the nearshore marine environment, the degree of increase is not expected to be substantially different from the existing condition; therefore, Hawaiian monk seal foraging habitat in the action area is not expected to substantially decrease from its current abundance within the action area.

Although BMPs are not defined for operation of the proposed project, the project does include a detention basin at the Ala Wai Golf Course that would collect storm water runoff from the Manoa-Palolo Canal, detain the runoff, and slowly release the runoff back into the Ala Wai Canal. The operation of the detention basin in conjunction with the floodwalls could minimize potential indirect impacts to Hawaiian monk seal foraging habitat from acceleration of the delivery of storm water runoff to the nearshore marine environment and the quality of storm water runoff reaching the nearshore marine environment. This is because storm water runoff from the Manoa-Palolo canal would be held within the detention basin for up to two days providing time for some sediments entrained within the water column to settle out in the detention basin. After approximately two days, the detained storm water runoff would begin to slowly be released back into the Ala Wai Canal. Sediment retained in the detention basin would then be collected and disposed of at an appropriate facility. With the operation of the detention basin, a negligible or no change to the sediment/nutrient concentration of the storm water runoff reaching the nearshore marine environment could occur and in turn minimize the potential impact on Hawaiian monk seal foraging habitat within the nearshore marine environment. Most of the sediment containing excess nutrients and legacy contaminants comes from the Manoa and Palolo streams which feed into the Manoa-Palolo Canal. Therefore, the operation of the detention basin—which would hold storm water runoff from these streams during a storm event and provide time for sedimentation to occur—has the potential to avoid or minimize the possible impact of the proposed project on increased nutrient and sediment loading to the nearshore marine environment and thereby minimize the potential for resulting habitat degradation of Hawaiian monk seal foraging habitat.

Critical Habitat

Activities associated with the proposed action that could reasonably be expected to impact designated marine critical habitat for the Hawaiian monk seal include:

1. Exposure to elevated turbidity and sedimentation; and
2. Exposure to wastes and discharges.

Exposure to elevated turbidity and sedimentation:

In-water construction activities have the potential to generate turbidity through disturbance of existing in-place substrates causing the resuspension of sediments into the water column, thereby raising ambient turbidity levels. Elevated turbidity levels over ambient turbidity levels

would degrade ambient water quality within the construction footprint and immediate surrounding area which could include proposed designated critical habitat for the green sea turtle. Elevated turbidity levels would be discrete, temporary, and are expected to naturally dissipate, restoring water quality to ambient levels with no anticipated permanent impact to water quality resulting from construction. Suspended sediments are expected to settle rather quickly upon completion of any in-water disturbances. Adverse impacts to the water column within the Ala Wai Canal due to construction related turbidity, are likely to be limited in both physical and temporal extent due to the lack of currents in the canal and use of avoidance and minimization measures listed under environmental commitments located further below in this section. The Ala Wai Canal is generally subjected to low flow velocities from tidal influence which naturally and considerably limit the potential for turbidity plumes to be carried into adjacent habitats (i.e., Ala Wai Small Boat Harbor, nearshore marine habitat, green sea turtle proposed designated critical habitat). Given that the Ala Wai Canal is subject to bouts of high turbidity during storm events under the existing condition, it is unlikely that temporary increases in turbidity from constructing/modifying existing drainage structures would have any measurable impact upon designated critical habitat for the Hawaiian monk seal.

As described under environmental commitments, located further below in this section, USACE has proposed BMPs (e.g., silt curtains) to contain resuspended sediments in the immediate in-water work areas during construction/modification of drainage structures to avoid spreading project-related, degraded water quality impacts to surrounding waters. In addition, USACE would stipulate to the contractor that no in-water construction activities could occur during periods of heavy rainfall. This would minimize the potential compounding adverse water quality impacts resulting from in-water construction work in combination with high turbidity levels from the Manoa-Palolo Canal during a storm event. Additionally, USACE is seeking a water quality certification under Section 401 of the Clean Water Act from the State of Hawaii Department of Health, Clean Water Branch (DOH-CWB). To obtain such certification, all proposed actions would comply with State water quality standards and implement necessary and appropriate monitoring BMPs to curtail water quality impacts.

The long-term operation of the project is passive, however, components of the project when working as a system could cause adverse indirect impacts to designated critical habitat for the Hawaiian monk seal from potential water quality degradation. Under the proposed project, turbidity plumes occurring during a storm event could carry higher sediment and nutrient concentrations and take additional time to dissipate upon reaching the nearshore marine environment. Therefore, medium to high turbidity levels could be experienced primarily at nearby designated critical habitat for the Hawaiian monk seal sooner than under the without project condition. Turbidity plumes extending into nearby designated critical habitat for the Hawaiian monk seal may also take longer than approximately 24 hours for dissipation to begin. The degraded water quality caused by the turbidity plumes could stimulate and sustain algae growth within the action area. Currently, frondose algae, crustose coralline algae, and turf algae are common but not dominant in the action area. Filamentous algae or cyanobacteria are also present primarily seaward of Waikiki beaches but do not dominate the habitat. While the proposed project is likely to increase nutrient and sediment concentrations reaching the nearshore marine environment during a storm event, the degree of increase in concentrations is not expected to stimulate algae growth in such a way that algae would be expected to become dominant in the action area and smoother corals that provide habitat for Hawaiian monk seal prey. Hawaiian monk seals are “generalist” feeders, meaning they eat a wide variety of foods depending on availability. Hawaiian monk seals eat many species of common fishes, squids, octopuses, eels, and crustaceans (crabs, shrimps, and lobsters). There could be slight increases in algae growth observed due to increased nutrient and sediment concentrations and

turbidity taking longer to begin to dissipate, but the increase in algae growth would not be expected to be substantial to cause a loss of foraging habitat for the Hawaiian monk seal in the action area. Overall, the proposed project is not expected to substantially affect foraging habitat for the Hawaiian monk seal; therefore, the proposed project is not expected to destroy or adversely modify designated critical habitat for the Hawaiian monk seal.

Exposure to discharges:

Although construction of the proposed action primarily occurs upland, construction activities are often located adjacent to the aquatic environment. Therefore, equipment spills and discharges likely consisting of hydrocarbon-based chemicals such as fuel oils, gasoline, lubricants, hydraulic fluids, and other toxicants, could enter the nearshore marine environment and designated critical habitat for the Hawaiian monk seal to toxic chemicals. Depending on the chemicals and their concentration, exposure could result in a range of effects. Regarding foraging habitat for the Hawaiian monk seal (i.e., designated critical habitat), inadvertent spills and discharges from construction equipment has the potential to quickly kill Hawaiian monk seal prey. Highly motile prey such as fish, squid, octopus, and eels may be able to avoid harm by moving out of the area. Highly motile prey is also expected to be able to recolonize the affected area faster once contamination is contained and/or dissipates. Less motile prey such as crabs, shrimps, and lobsters are likely to be killed. Less motile prey is also expected to take longer to recolonize the affected area once contamination is contained and/or dissipates. Although inadvertent spills and discharges from construction equipment have the potential to kill Hawaiian monk seal prey, motile prey are expected to be able to avoid harm and recolonize the area quickly. Less motile prey species would likely take longer to recolonize the area, but since Hawaiian monk seals eat a wide variety of foods depending on availability, diet for the seals would likely consist of more motile species until less motile species are able to recolonize the area. It is important to note that local and Federal regulations prohibit the intentional discharge of toxic wastes and plastics into the marine environment. In addition, BMPs listed further below in this section under environmental commitments include measures intended to prevent or reduce exposure of the marine environment to wastes and discharges from construction equipment. Based on the above and the implementation of measures located further below in this section under environmental commitments, the proposed project is not expected to substantially affect foraging habitat for the Hawaiian monk seal; therefore, the proposed project is not expected to destroy or adversely modify designated critical habitat for the Hawaiian monk seal.

Overall, the proposed action involves minor in-water work which could expose Hawaiian monk seal to project-related activity. However, with the implementation of avoidance and minimization measures listed under environmental commitments located further below in this section potential impacts to Hawaiian monk seal due to project-related activity is expected to be minimized such that the proposed action may affect, but is not likely to adversely affect Hawaiian monk seal or designated critical habitat for Hawaiian monk seal.

Green Sea Turtle (ESA status – Threatened): Activities associated with the proposed action could reasonably be expected to interact directly or indirectly with green sea turtle through:

1. Collision with vessels;
2. Direct physical impact;
3. Disturbance from human activity and equipment operation;
4. Exposure to elevated noise levels;
5. Exposure to elevated turbidity;
6. Exposure to wastes and discharges; and

7. Loss of forage habitat.

Collision with vessels:
Activities associated with the proposed action do not include the use of vessels in nearshore marine waters or lower reaches of rivers and streams. All work is anticipated to occur from upland with equipment staged upland.

Direct physical impact:
Activities associated with the proposed action do not include the use of vessels in nearshore Physical impact to green sea turtle is not expected to occur. At this time, all construction work would occur from upland with no construction equipment (i.e., push barge, vessel, etc.) anticipated to be present within the aquatic habitat. The exception is construction of the Ala Wai Canal floodwall which includes upgrading existing stormwater drainage outlets. Upgrades would potentially include increasing the size of the outlets and/or installing flap gates on the outlets. While some outlets would be accessible from upland and would not require in-water work, some of the outlets to be upgraded could be at water level or below water level. For outlets that cannot be upgraded from land only, minor in-water work would occur. In-water work would require the placement of a cofferdam around the work area. The placement of cofferdam materials could potentially physically impact green sea turtle should these animals be present when cofferdam materials strike the bottom. Potential injuries and their severity will depend on the animal's proximity to the bottom when struck, the angle of the strike, and the body part impacted, but may include cuts, bruises, broken bones, and amputations, any of which could result in the animal's death. Green sea turtle could also be pinned to the bottom and drowned. To minimize potential physical impacts to green sea turtle during cofferdam material placement, avoidance and minimization measures listed under environmental commitments, located further below in this section, would be implemented. Some of these avoidance and minimization measures require surveys for ESA-listed species in the area to occur prior to the start of each workday and prior to resumption of work following any break of more than one-half hour. They also require that all work be postponed or halted when motile ESA-listed marine species are within 164 feet of proposed work and resumption of activities should only occur after the animals have voluntarily left the area. These types of avoidance and minimization measures listed under environmental commitments, located further below in this section, would minimize the potential physical impact to green sea turtle during the placement and removal of cofferdam material.

Much of the construction for the proposed action would occur upland and adjacent to waterways, not within a waterway. Construction of the Ala Wai Canal floodwall, however, includes upgrading existing stormwater drainage outlets. Upgrades would potentially include increasing the size of the outlets and/or installing flap gates on the outlets. While some outlets would be accessible from upland and would not require in-water work, some of the outlets to be upgraded could be at water level or below water level. For outlets that cannot be upgraded from land only, minor in-water work would occur. In-water work would require the placement of a cofferdam around the work area, pumping the work area within the cofferdam dry, performing the upgrades, and then removal of the cofferdam materials. The size of the cofferdam would be the minimum necessary to perform the upgrade work. Placement of the cofferdam and removal of the cofferdam would potentially expose green sea turtles to project-related activity. However, sea turtles typically avoid human activity, so exposure to the project-related activity detailed above would be infrequent and non-injurious. In addition, avoidance and minimization measures would be implemented during construction such that in insignificant effects on the green sea turtle are anticipated.

Exposure to elevated noise levels:

Activities such as pile-driving may produce in-air and in-water sound levels capable of injury or adverse behavioral modifications for green sea turtle. Much of the construction for the proposed action would occur upland and adjacent to waterways, not within a waterway. For example, construction of the floodwalls along Manoa-Palolo Canal and the Ala Wai Canal would occur upland. In addition, most of the floodwalls being constructed do not include pile driving; the exception being the reach along the right-descending bank of the Manoa-Palolo Canal between Kapiolani Boulevard and Date Street. In this reach, the upland area is constricted to such a degree that a steel sheet pile wall (i.e., I-wall) would need to be installed in this location. A 15-foot-wide rock bench would be placed in-water along the right-descending bank of the Manoa-Palolo Canal parallel to the bank. Equipment for construction of the I-wall would be staged along this rock bench. Upon completion of the I-Wall, the rock bench would be permanently removed. Although equipment for constructing of the floodwall would be staged along the 15-foot-wide rock bench, inserting the steel sheet pile for the floodwall would be into the adjacent upland area. The method to be used would be push in place instead of impact pile driving. The push in place method pushes the steel sheet pile into the ground without an impact hammer or vibration. The operation, except for a crane engine (to hold the steel sheet pile) and the generator to power the machine for pushing in the pile, is almost silent. For reference, a crane and a generator typically produce airborne noise levels of 87 dBA at 50 feet from the source. Therefore, using the push in place method would reduce airborne noise levels typically associated with pile driving as well as in water noise levels. In addition, installation of pile would be upland where it is in the dry. Pile installation in the dry is typically a minimization measure designed to reduce the amount of sound that is transmitted through water. Although there is no method for calculating sound transmission loss through soil outside of the water, and then calculating the loss in water, it is assumed that transmission loss through soil is greater than what occurs in water or air due to the density of soil. Since pile installation would occur upland, this would be like pile driving occurring in the dry; therefore, installing the pile upland is expected to be effective at minimizing the effects of sound in adjacent aquatic habitat and protecting green sea turtle from potential noise-related impacts.

The floodwall along the Ala Wai Canal does not include the installation of steel sheet pile. Instead, floodwalls along the Ala Wai Canal would be either J-walls or L-walls on macropiles. The macropiles require the use of a drill rig and associated drilling equipment to create a hole to design depth. The drill rig and drilling of the macropile hole would likely create the most noise during construction of these types of floodwalls. However, like the pile installation along the reach of Manoa-Palolo Canal, drilling would occur upland which is effective at minimizing the effects of sound in the water. Although there is no method for calculating sound transmission loss through soil outside of the water, and then calculating the loss in water, it is assumed that transmission loss through soil is greater than what occurs in water or air due to the density of soil. Since drilling of the macropile holes would occur upland, this is expected to be effective at minimizing the effects of sound in adjacent aquatic habitat and protecting green sea turtle from potential noise-related impacts.

In addition to construction of floodwall, the Ala Wai Canal floodwall also includes upgrading existing stormwater drainage outlets. Upgrades would potentially include increasing the size of the outlets and/or installing flap gates on the outlets. While some outlets would be accessible from upland and would not require in-water work, some of the outlets to be upgraded could be at water level or below water level. For outlets that cannot be upgraded from land only, minor in-water work would occur. In-water work would require the placement of a cofferdam around the work area, pumping the work area within the cofferdam dry, performing the upgrades, and then removal of the cofferdam materials. The size of the cofferdam would be the minimum necessary to perform the upgrade work. Placement of the cofferdam and removal of the cofferdam would

potentially expose green sea turtle to project-related activity. However, green sea turtles typically avoid human interaction, so exposure to the project-related activity detailed above would be infrequent and non-injurious. The presence of the cofferdam would allow work on the stormwater drainage structures to be completed in the dry. As stated previously, working in the dry is a minimization measure designed to reduce the amount of sound that is transmitted through the water. Therefore, upgrading existing stormwater outlet structures would occur in the dry which is expected to be effective at minimizing the effects of sound in adjacent aquatic habitat and protecting green sea turtle from potential noise-related impacts.

Exposure to elevated turbidity and sedimentation:
In-water construction activities have the potential to generate turbidity through disturbance of existing in-place substrates causing the resuspension of sediments into the water column, thereby raising ambient turbidity levels. Elevated turbidity levels over ambient turbidity levels would degrade ambient water quality within the construction footprint and immediate surrounding area. Elevated turbidity levels would be discrete, temporary, and are expected to naturally dissipate, restoring water quality to ambient levels with no anticipated permanent impact to water quality resulting from construction. Suspended sediments are expected to settle rather quickly upon completion of any in-water disturbances. Adverse impacts to the water column within the Ala Wai Canal due to construction related turbidity, are likely to be limited in both physical and temporal extent due to the lack of currents in the canal and use of avoidance and minimization measures listed under environmental commitments, located further below in this section. The Ala Wai Canal is generally subjected to low flow velocities from tidal influence which naturally and considerably limit the potential for turbidity plumes to be carried into adjacent habitats (i.e., Ala Wai Small Boat Harbor, nearshore marine habitat). Given that the Ala Wai Canal is subject to bouts of high turbidity during storm events under the existing condition, it is unlikely that temporary increases in turbidity from constructing/modifying existing drainage structures would have any measurable impact upon green sea turtle.

As described under environmental commitments, located further below in this section, USACE has proposed BMPs (e.g., silt curtains) to contain resuspended sediments in the immediate in-water work areas during construction/modification of drainage structures to avoid spreading project-related, degraded water quality impacts to surrounding waters. In addition, USACE would stipulate to the contractor that no in-water construction activities could occur during periods of heavy rainfall. This would minimize the potential compounding adverse water quality impacts resulting from in-water construction work in combination with high turbidity levels from the Manoa-Palolo Canal during a storm event. Additionally, USACE is seeking a water quality certification under Section 401 of the Clean Water Act from the State of Hawaii Department of Health, Clean Water Branch (DOH-CWB). To obtain such certification, all proposed actions would comply with State water quality standards and implement necessary and appropriate monitoring BMPs to curtail water quality impacts.

The operation of the project is passive, however, components of the project when working as a system could cause adverse indirect impacts to marine habitat occupied by the green sea turtle due to water quality degradation. The project includes the construction of floodwalls primarily along the Ala Wai Canal (including Manoa-Palolo Canal). Floodwalls would increase the capacity of the Ala Wai Canal to hold more storm water as well as increase storm flow velocities in the canal. Increased storm flow velocities in the canal could in turn disturb and/or resuspend sediments in the water column creating a turbidity plume that could affect water quality in the canal, the Ala Wai Small Boat Harbor, and the nearshore marine environment. Changes to velocities within the Ala Wai Canal were modeled with project features constructed and are compared against velocities within the canal under existing conditions in Table 40. Although the

project would result in increased velocities and likely a large turbidity plume during a storm event, it is important to note that increased velocities and turbidity plumes already occur under the existing condition during a storm event.

Currently, under existing conditions, high rainfall events disturb sediments in the upper reaches of the Ala Wai watershed and cause these sediments to become suspended in the water column. There are also three general areas in the Ala Wai Canal where previously suspended sediments have sedimented out and built up within the canal: Kalakaua Avenue Bridge, mouth of the Manoa-Palolo Canal, and the terminus of the Ala Wai Canal (Montgomery et al., 2009). These built-up sediments within the canal at these locations can become resuspended in the water column during a storm event due to increased water velocities within the canal. The combination of these suspended sediments in the water column cause turbidity plumes during storm events which can extend beyond the canal and degrade water quality within the nearshore marine environment. Predicting how far turbidity plumes could extend during a storm event is difficult and can in turn make it difficult to predict where impacts to the nearshore marine environment could occur. However, PacIOOS has developed a turbidity plume forecast model for the Ala Wai Canal allowing the tracking of potential turbidity levels and extent of turbidity plumes along the nearshore marine environment. As an example of how a turbidity plume might extend out of the Ala Wai Small Boat Harbor and into the nearshore marine environment, PacIOOS conducted a model run of a turbidity plume for a storm event that occurred December 25 through December 27, 2017, in the Honolulu area. Figure 23 shows selected time progressions of this storm's modeled turbidity plume.

As seen in Figure 23, at the beginning of the storm event (i.e., December 25; 23:00 HST) the Ala Wai Canal begins to experience high turbidity with low turbidity beginning to occur within the Ala Wai Small Boat Harbor. Following approximately 12 hours (i.e., December 26, 2017; 12:00 HST), high turbidity is experienced throughout Ala Wai Canal and Ala Wai Small Boat Harbor, while low to medium turbidity is beginning to occur along the reef flat area outside of Ala Wai Harbor and within the vicinity of the Atlantis Submarines harbor. Following the passage of another 12 hours (i.e., December 26, 2017; 23:00 HST), high turbidity continues to be experienced throughout the Ala Wai Canal, but high turbidity within the Ala Wai Boat Harbor is beginning to dissipate. Similarly, medium turbidity is still being experienced within the vicinity of the Atlantis Submarines Harbor and low turbidity is being experienced along the nearshore marine area (reef flat)—within the vicinity of the Sheraton Hotel on Waikiki. Following the passage of another 6 hours (i.e., December 27, 201; 06:00 HST), the turbidity plume begins to dissipate along the nearshore marine area, although low turbidity is still being experienced. Turbidity within the Ala Wai Boat Harbor has also begun to dissipate currently with moderate turbidity occurring in the harbor. Over the course of the following 18 hours, from 12:00 HST to 23:00 HST on December 27, 2017, the turbidity plume further dissipates, although low/medium turbidity is still being experienced within the Ala Wai Boat Harbor and the harbor channel. In addition, the Ala Wai Canal is experiencing medium turbidity still after approximately 48 hours has passed from the beginning of the storm event. The above details a potential turbidity plume under the future without project condition. This means that even under the future without project condition, marine habitat located within Ala Wai Harbor generally experiences high turbidity during a storm event while marine habitat located outside the Ala Wai Boat Harbor and along Waikiki Beach experiences medium to low turbidity during a storm event.

During a storm event under the future without project condition, marine habitat in the harbor (Ala Wai Small Boat Harbor and Atlantis Submarines Harbor), reef flat (adjacent to Ala Wai Small Boat Harbor), reef crest (near Ala Wai Small Boat Harbor), fore reef (near Ala Wai Small Boat Harbor), and bank/shelf (near Ala Wai Small Boat Harbor) zones experiences medium to high

turbidity for approximately 24 hours (depending on the size of the storm event) before turbidity begins to dissipate. Low turbidity during this same time occurs in the shoreline intertidal and reef flat zones between the Atlantis Submarines Harbor and the Sheraton Hotel in Waikiki. Between approximately 24 and 48 hours (depending on the size of the storm event) following a storm event, turbidity within the harbor zone has been reduced to medium levels while turbidity along shoreline intertidal, reef flat, reef crest, fore reef, and bank/shelf zones has been reduced to low or clear levels.

Under the proposed project, turbidity plumes occurring during a storm event could carry higher sediment and nutrient concentrations and take additional time to dissipate upon reaching the nearshore marine environment. Therefore, medium to high turbidity levels could be experienced at the harbor, reef flat, reef crest, fore reef, and bank/shelf zones sooner than under the without project condition. Turbidity plumes extending into the nearshore marine environment may also take longer than approximately 24 hours for dissipation to begin. Elevated turbidity and sedimentation may impact green sea turtle. However, given that green sea turtles breathe air instead of water, increased turbidity should not adversely affect their respiration or other biological function.

Although BMPs are not defined for operation of the proposed project, the project does include a detention basin at the Ala Wai Golf Course that would collect storm water runoff from the Manoa-Palolo Canal, detain the runoff, and slowly release the runoff back into the Ala Wai Canal. The operation of the detention basin in conjunction with the floodwalls could minimize potential indirect impacts to marine habitat utilized by green sea turtle from acceleration of the delivery of storm water runoff to the nearshore marine environment and the quality of storm water runoff reaching the nearshore marine environment. This is because storm water runoff from the Manoa-Palolo canal would be held within the detention basin for up to two days providing time for some sediments entrained within the water column to settle out in the detention basin. After approximately two days, the detained storm water runoff would begin to slowly be released back into the Ala Wai Canal. Sediment retained in the detention basin would then be collected and disposed of at an appropriate facility. With the operation of the detention basin, a negligible or no change to the sediment/nutrient concentration of the storm water runoff reaching the nearshore marine environment could occur. Most of the sediment containing excess nutrients and legacy contaminants comes from the Manoa and Palolo streams which feed into the Manoa-Palolo Canal. Therefore, the operation of the detention basin—which would hold storm water runoff from these streams during a storm event and provide time for sedimentation to occur—has the potential to avoid or minimize the possible impact of the proposed project on increased nutrient and sediment loading to the nearshore marine environment. The operation of the detention basin could also help avoid and minimize the potential impact of the proposed project on accelerated discharge of freshwater to the nearshore marine environment.

Exposure to wastes and discharges:
Although construction of the proposed action primarily occurs upland, construction activities are often located adjacent to the aquatic environment. Therefore, construction waste may end up in the aquatic environment if not properly disposed of. Construction wastes may include plastic trash and bags that may be ingested and cause digestive blockage or suffocation, or if large enough, along with discarded sections of ropes and lines, may entangle green sea turtle. Equipment spills and discharges likely consist of hydrocarbon-based chemicals such as fuel oils, gasoline, lubricants, hydraulic fluids, and other toxicants, which could expose green sea turtles to toxic chemicals. Depending on the chemicals and their concentration, exposure could result in a range of effects, from avoidance of an area to death. Local and Federal regulations

prohibit the intentional discharge of toxic wastes and plastics into the marine environment. In addition, BMPs listed under environmental commitments, located further below in this section, include measures intended to prevent or reduce exposure of green sea turtles to wastes and discharges in the marine environment.

Loss of forage habitat:
Short-term, the loss of forage habitat could occur with the upgrading/modification of stormwater drainage structures which has the potential to be in habitat where green sea turtles may forage. The upgrading/modification of drainage structures includes the temporary placement of cofferdam materials within the Ala Wai Canal which may impact forage species through damage or destruction. At the level of the individual, the loss of significant levels of available forage may lead to lower growth rates, reduced fitness, reduced reproductive success, and potential death by starvation. At the population level, significantly reduced forage opportunities may eventually cause local extirpation through the death or emigration of members of that population.

The upgrading and/or modification of stormwater drainage structures would occur from upland if the structure is located above the water level of the canal. If the stormwater drainage structure is located at water level or below water level a cofferdam would need to be constructed so that upgrading and/or modification of the drainage structure could occur in the dry. The placement of cofferdam material would occupy the smallest footprint possible, therefore, limited in-water substrate disturbance is anticipated to occur. Once upgrading/modification of the drainage structure is complete the cofferdam would be removed in its entirety. Therefore, the loss of potential forage habitat located within the cofferdam footprint would be temporary because epibenthic life would likely re-colonize the area once the structure is removed.

Long-term, the operation of the proposed action could cause sediment mobilization that has the potential to smother forage resources. An increase in suspended sediments during a storm event, above that experienced under the future without project condition, would likely result in increased deposition rates within the canal and nearshore marine areas. According to the Ala Wai Canal Watershed Water Quality Improvement Project (City and County of Honolulu, 1998), sedimentation in the Ala Wai Canal occurs at the rate of about 10,300 CY per year. Sedimentation is also prevalent in the Manoa-Palolo Canal which receives the first flush from storm waters. Increased sedimentation in nearshore marine waters could smother green sea turtle foraging habitat. Although the proposed project is expected to potentially increase sediment delivery to the nearshore marine environment, the degree of increase is not expected to be substantially different from the existing condition; therefore, green sea turtle foraging habitat in the action area is not expected to substantially decrease from its current abundance within the action area.

Although BMPs are not defined for operation of the proposed project, the project does include a detention basin at the Ala Wai Golf Course that would collect storm water runoff from the Manoa-Palolo Canal, detain the runoff, and slowly release the runoff back into the Ala Wai Canal. The operation of the detention basin in conjunction with the floodwalls could minimize potential indirect impacts to green sea turtle foraging habitat from acceleration of the delivery of storm water runoff to the nearshore marine environment and the quality of storm water runoff reaching the nearshore marine environment. This is because storm water runoff from the Manoa-Palolo canal would be held within the detention basin for up to two days providing time for some sediments entrained within the water column to settle out in the detention basin. After approximately two days, the detained storm water runoff would begin to slowly be released back into the Ala Wai Canal. Sediment retained in the detention basin would then be collected and disposed of at an appropriate facility. With the operation of the detention basin, a negligible or

no change to the sediment/nutrient concentration of the storm water runoff reaching the nearshore marine environment could occur and in turn minimize the potential impact on green sea turtle foraging habitat within the nearshore marine environment. Most of the sediment containing excess nutrients and legacy contaminants comes from the Manoa and Palolo streams which feed into the Manoa-Palolo Canal. Therefore, the operation of the detention basin—which would hold storm water runoff from these streams during a storm event and provide time for sedimentation to occur—has the potential to avoid or minimize the possible impact of the proposed project on increased nutrient and sediment loading to the nearshore marine environment and thereby minimize the potential for resulting habitat degradation of green sea turtle foraging habitat.

Critical Habitat

Activities associated with the proposed action that could reasonably be expected to impact proposed designated habitat for the green sea turtle include:

1. Exposure to elevated turbidity and sedimentation; and
2. Exposure to wastes and discharges.

Exposure to elevated turbidity and sedimentation:

In-water construction activities have the potential to generate turbidity through disturbance of existing in-place substrates causing the resuspension of sediments into the water column, thereby raising ambient turbidity levels. Elevated turbidity levels over ambient turbidity levels would degrade ambient water quality within the construction footprint and immediate surrounding area which could include proposed designated critical habitat for the green sea turtle. Elevated turbidity levels would be discrete, temporary, and are expected to naturally dissipate, restoring water quality to ambient levels with no anticipated permanent impact to water quality resulting from construction. Suspended sediments are expected to settle rather quickly upon completion of any in-water disturbances. Adverse impacts to the water column within the Ala Wai Canal due to construction related turbidity, are likely to be limited in both physical and temporal extent due to the lack of currents in the canal and use of avoidance and minimization measures listed under environmental commitments, located further below in this section. The Ala Wai Canal is generally subjected to low flow velocities from tidal influence which naturally and considerably limit the potential for turbidity plumes to be carried into adjacent habitats (i.e., Ala Wai Small Boat Harbor, nearshore marine habitat, green sea turtle proposed designated critical habitat). Given that the Ala Wai Canal is subject to bouts of high turbidity during storm events under the existing condition, it is unlikely that temporary increases in turbidity from constructing/modifying existing drainage structures would have any measurable impact upon proposed designated critical habitat for the green sea turtle.

As described under environmental commitments, located further below in this section, USACE has proposed BMPs (e.g., silt curtains) to contain resuspended sediments in the immediate in-water work areas during construction/modification of drainage structures to avoid spreading project-related, degraded water quality impacts to surrounding waters. In addition, USACE would stipulate to the contractor that no in-water construction activities could occur during periods of heavy rainfall. This would minimize the potential compounding adverse water quality impacts resulting from in-water construction work in combination with high turbidity levels from the Manoa-Palolo Canal during a storm event. Additionally, USACE is seeking a water quality certification under Section 401 of the Clean Water Act from the State of Hawaii Department of Health, Clean Water Branch (DOH-CWB). To obtain such certification, all proposed actions would comply with State water quality standards and implement necessary and appropriate monitoring BMPs to curtail water quality impacts.

The long-term operation of the project is passive, however, components of the project when working as a system could cause adverse indirect impacts to proposed designated critical habitat for the green sea turtle from potential water quality degradation. Under the proposed project, turbidity plumes occurring during a storm event could carry higher sediment and nutrient concentrations and take additional time to dissipate upon reaching the nearshore marine environment. Therefore, medium to high turbidity levels could be experienced primarily at nearby proposed designated critical habitat for the green sea turtle sooner than under the without project condition. Turbidity plumes extending into nearby proposed designated critical habitat for the green sea turtle may also take longer than approximately 24 hours for dissipation to begin. The degraded water quality caused by the turbidity plumes could stimulate and sustain algae growth within the action area. Currently, frondose algae, crustose coralline algae, and turf algae are common but not dominant in the action area (USFWS, 2023b). Filamentous algae or cyanobacteria are also present primarily seaward of Waikiki beaches but do not dominate the habitat (USFWS, 2023b). While the proposed project is likely to increase nutrient and sediment concentrations reaching the nearshore marine environment during a storm event, the degree of increase in concentrations is not expected to stimulate algae growth in such a way that algae would be expected to become dominant in the action area. Green sea turtles are herbivores and eat mostly seagrasses and algae. Although the project is not expected to significantly stimulate algae growth, the project is also not expected to substantially decrease algae growth beyond that which currently occurs in the action area. Overall, the proposed project is not expected to substantially affect foraging habitat for the green sea turtle; therefore, the proposed project is not expected to destroy or adversely modify proposed designated critical habitat for the green sea turtle.

Exposure to discharges:

Although construction of the proposed action primarily occurs upland, construction activities are often located adjacent to the aquatic environment. Therefore, equipment spills and discharges likely consisting of hydrocarbon-based chemicals such as fuel oils, gasoline, lubricants, hydraulic fluids, and other toxicants, could enter the nearshore marine environment and proposed designated critical habitat for the green sea turtle to toxic chemicals. Depending on the chemicals and their concentration, exposure could result in a range of effects. Regarding foraging habitat for the green sea turtle (i.e., proposed designated critical habitat), inadvertent spills and discharges from construction equipment has the potential to quickly kill algae filaments; however, populations may recover rapidly by growth and vegetative reproduction of any unharmed fragments or spores (O'Brien and Dixon, 1976). Although inadvertent spills and discharges from construction equipment have the potential to kill algae, hydrocarbon-based chemicals generally have a greater adverse impact on algal grazers than algae (O'Brien and Dixon, 1976). Therefore, inadvertent spills and discharges would likely kill algal grazers and result in a temporary increase in algae until algal grazers are able to recolonize the impacted area (O'Brien and Dixon, 1976). It is important to note that local and Federal regulations prohibit the intentional discharge of toxic wastes and plastics into the marine environment. In addition, BMPs listed under environmental commitments, located further below in this section, include measures intended to prevent or reduce exposure of the marine environment to wastes and discharges from construction equipment. Based on the above and the implementation of measures under environmental commitments, located further below in this section, the proposed project is not expected to substantially affect foraging habitat for the green sea turtle; therefore, the proposed project is not expected to destroy or adversely modify proposed designated critical habitat for the green sea turtle.

Overall, the proposed action involves minor in-water work which could expose green sea turtle to project-related activity. However, with the implementation of avoidance and minimization

measures listed under environmental commitments, located further below in this section, potential impacts to green sea turtle due to project-related activity is expected to be minimized such that the proposed action may affect, but is not likely to adversely affect green sea turtle or proposed designated critical habitat for green sea turtle.

Hawksbill Sea Turtle (ESA status – Endangered): Activities associated with the proposed action could reasonably be expected to interact directly or indirectly with hawksbill sea turtle through:

1. Collision with vessels;
2. Direct physical impact;
3. Disturbance from human activity and equipment operation;
4. Exposure to elevated noise levels;
5. Exposure to elevated turbidity;
6. Exposure to wastes and discharges; and
7. Loss of forage habitat.

Collision with vessels:
Activities associated with the proposed action do not include the use of vessels in nearshore marine waters or lower reaches of rivers and streams. All work is anticipated to occur from upland with equipment staged upland.

Direct physical impact:
Activities associated with the proposed action do not include the use of vessels in nearshore Physical impact to hawksbill sea turtle is not expected to occur. At this time, all construction work would occur from upland with no construction equipment (i.e., push barge, vessel, etc.) anticipated to be present within the aquatic habitat. The exception is construction of the Ala Wai Canal floodwall which includes upgrading existing stormwater drainage outlets. Upgrades would potentially include increasing the size of the outlets and/or installing flap gates on the outlets. While some outlets would be accessible from upland and would not require in-water work, some of the outlets to be upgraded could be at water level or below water level. For outlets that cannot be upgraded from land only, minor in-water work would occur. In-water work would require the placement of a cofferdam around the work area. The placement of cofferdam materials could potentially physically impact hawksbill sea turtles should these animals be present when cofferdam materials strike the bottom. Potential injuries and their severity will depend on the animal's proximity to the bottom when struck, the angle of the strike, and the body part impacted, but may include cuts, bruises, broken bones, and amputations, any of which could result in the animal's death. Hawksbill sea turtle could also be pinned to the bottom and drowned. To minimize potential physical impacts to hawksbill sea turtle during cofferdam material placement, avoidance and minimization measures listed under environmental commitments, located further below in this section, would be implemented. Some of these avoidance and minimization measures require surveys for ESA-listed species in the area to occur prior to the start of each workday and prior to resumption of work following any break of more than one-half hour. They also require that all work be postponed or halted when motile ESA-listed marine species are within 164 feet of proposed work and resumption of activities should only occur after the animals have voluntarily left the area. These types of avoidance and minimization measures (refer to environmental commitments located further below in this section for the complete list) would minimize the potential physical impact to hawksbill sea turtle during the placement and removal of cofferdam material.

Much of the construction for the proposed action would occur upland and adjacent to waterways, not within a waterway. Construction of the Ala Wai Canal floodwall, however, includes upgrading existing stormwater drainage outlets. Upgrades would potentially include increasing the size of the outlets and/or installing flap gates on the outlets. While some outlets would be accessible from upland and would not require in-water work, some of the outlets to be upgraded could be at water level or below water level. For outlets that cannot be upgraded from land only, minor in-water work would occur. In-water work would require the placement of a cofferdam around the work area, pumping the work area within the cofferdam dry, performing the upgrades, and then removal of the cofferdam materials. The size of the cofferdam would be the minimum necessary to perform the upgrade work. Placement of the cofferdam and removal of the cofferdam would potentially expose hawksbill sea turtles to project-related activity. However, sea turtles typically avoid human activity, so exposure to the project-related activity detailed above would be infrequent and non-injurious. In addition, avoidance and minimization measures would be implemented during construction such that in insignificant effects on the hawksbill sea turtle are anticipated.

Exposure to elevated noise levels:
Activities such as pile-driving may produce in-air and in-water sound levels capable of injury or adverse behavioral modifications for hawksbill sea turtle. Much of the construction for the proposed action would occur upland and adjacent to waterways, not within a waterway. For example, construction of the floodwalls along Manoa-Palolo Canal and the Ala Wai Canal would occur upland. In addition, most of the floodwalls being constructed do not include pile driving; the exception being the reach along the right-descending bank of the Manoa-Palolo Canal between Kapiolani Boulevard and Date Street. In this reach, the upland area is constricted to such a degree that a steel sheet pile wall (i.e., I-wall) would need to be installed in this location. A 15-foot-wide rock bench would be placed in-water along the right-descending bank of the Manoa-Palolo Canal parallel to the bank. Equipment for construction of the I-wall would be staged along this rock bench. Upon completion of the I-Wall, the rock bench would be permanently removed. Although equipment for constructing of the floodwall would be staged along the 15-foot-wide rock bench, inserting the steel sheet pile for the floodwall would be into the adjacent upland area. The method to be used would be push in place instead of impact pile driving. The push in place method pushes the steel sheet pile into the ground without an impact hammer or vibration. The operation, except for a crane engine (to hold the steel sheet pile) and the generator to power the machine for pushing in the pile, is almost silent. For reference, a crane and a generator typically produce airborne noise levels of 87 dBA at 50 feet from the source. Therefore, using the push in place method would reduce airborne noise levels typically associated with pile driving as well as in water noise levels. In addition, installation of pile would be upland where it is in the dry. Pile installation in the dry is typically a minimization measure designed to reduce the amount of sound that is transmitted through water. Although there is no method for calculating sound transmission loss through soil outside of the water, and then calculating the loss in water, it is assumed that transmission loss through soil is greater than what occurs in water or air due to the density of soil. Since pile installation would occur upland, this would be like pile driving occurring in the dry; therefore, installing the pile upland is expected to be effective at minimizing the effects of sound in adjacent aquatic habitat and protecting Hawaiian monk seal from potential noise-related impacts.

The floodwall along the Ala Wai Canal does not include the installation of steel sheet pile. Instead, floodwalls along the Ala Wai Canal would be either J-walls or L-walls on macropiles. The macropiles require the use of a drill rig and associated drilling equipment to create a hole to design depth. The drill rig and drilling of the macropile hole would likely create the most noise during construction of these types of floodwalls. However, like the pile installation along the

reach of Manoa-Palolo Canal, drilling would occur upland which is effective at minimizing the effects of sound in the water. Although there is no method for calculating sound transmission loss through soil outside of the water, and then calculating the loss in water, it is assumed that transmission loss through soil is greater than what occurs in water or air due to the density of soil. Since drilling of the macropile holes would occur upland, this is expected to be effective at minimizing the effects of sound in adjacent aquatic habitat and protecting Hawaiian monk seal from potential noise-related impacts.

In addition to construction of floodwall, the Ala Wai Canal floodwall also includes upgrading existing stormwater drainage outlets. Upgrades would potentially include increasing the size of the outlets and/or installing flap gates on the outlets. While some outlets would be accessible from upland and would not require in-water work, some of the outlets to be upgraded could be at water level or below water level. For outlets that cannot be upgraded from land only, minor in-water work would occur. In-water work would require the placement of a cofferdam around the work area, pumping the work area within the cofferdam dry, performing the upgrades, and then removal of the cofferdam materials. The size of the cofferdam would be the minimum necessary to perform the upgrade work. Placement of the cofferdam and removal of the cofferdam would potentially expose hawksbill sea turtle to project-related activity. However, Hawaiian monk seals typically avoid human interaction, so exposure to the project-related activity detailed above would be infrequent and non-injurious. The presence of the cofferdam would allow work on the stormwater drainage structures to be completed in the dry. As stated previously, working in the dry is a minimization measure designed to reduce the amount of sound that is transmitted through the water. Therefore, upgrading existing stormwater outlet structures would occur in the dry which is expected to be effective at minimizing the effects of sound in adjacent aquatic habitat and protecting hawksbill sea turtle from potential noise-related impacts.

Exposure to elevated turbidity and sedimentation:
In-water construction activities have the potential to generate turbidity through disturbance of existing in-place substrates causing the resuspension of sediments into the water column, thereby raising ambient turbidity levels. Elevated turbidity levels over ambient turbidity levels would degrade ambient water quality within the construction footprint and immediate surrounding area. Elevated turbidity levels would be discrete, temporary, and are expected to naturally dissipate, restoring water quality to ambient levels with no anticipated permanent impact to water quality resulting from construction. Suspended sediments are expected to settle rather quickly upon completion of any in-water disturbances. Adverse impacts to the water column within the Ala Wai Canal due to construction related turbidity, are likely to be limited in both physical and temporal extent due to the lack of currents in the canal and use of avoidance and minimization measures listed under environmental commitments, located further below in this section. The Ala Wai Canal is generally subjected to low flow velocities from tidal influence which naturally and considerably limit the potential for turbidity plumes to be carried into adjacent habitats (i.e., Ala Wai Small Boat Harbor, nearshore marine habitat). Given that the Ala Wai Canal is subject to bouts of high turbidity during storm events under the existing condition, it is unlikely that temporary increases in turbidity from constructing/modifying existing drainage structures would have any measurable impact upon hawksbill sea turtle.

As described under environmental commitments, located further below in this section, USACE has proposed BMPs (e.g., silt curtains) to contain resuspended sediments in the immediate in-water work areas during construction/modification of drainage structures to avoid spreading project-related, degraded water quality impacts to surrounding waters. In addition, USACE would stipulate to the contractor that no in-water construction activities could occur during periods of heavy rainfall. This would minimize the potential compounding adverse water quality

impacts resulting from in-water construction work in combination with high turbidity levels from the Manoa-Palolo Canal during a storm event. Additionally, USACE is seeking a water quality certification under Section 401 of the Clean Water Act from the State of Hawaii Department of Health, Clean Water Branch (DOH-CWB). To obtain such certification, all proposed actions would comply with State water quality standards and implement necessary and appropriate monitoring BMPs to curtail water quality impacts.

The operation of the project is passive, however, components of the project when working as a system could cause adverse indirect impacts to marine habitat occupied by the hawksbill sea turtle due to water quality degradation. The project includes the construction of floodwalls primarily along the Ala Wai Canal (including Manoa-Palolo Canal). Floodwalls would increase the capacity of the Ala Wai Canal to hold more storm water as well as increase storm flow velocities in the canal. Increased storm flow velocities in the canal could in turn disturb and/or resuspend sediments in the water column creating a turbidity plume that could affect water quality in the canal, the Ala Wai Small Boat Harbor, and the nearshore marine environment. Changes to velocities within the Ala Wai Canal were modeled with project features constructed and are compared against velocities within the canal under existing conditions in Table 40. Although the project would result in increased velocities and likely a large turbidity plume during a storm event, it is important to note that increased velocities and turbidity plumes already occur under the existing condition during a storm event.

Currently, under existing conditions, high rainfall events disturb sediments in the upper reaches of the Ala Wai watershed and cause these sediments to become suspended in the water column. There are also three general areas in the Ala Wai Canal where previously suspended sediments have sedimented out and built up within the canal: Kalakaua Avenue Bridge, mouth of the Manoa-Palolo Canal, and the terminus of the Ala Wai Canal (Montgomery et al., 2009). These built-up sediments within the canal at these locations can become resuspended in the water column during a storm event due to increased water velocities within the canal. The combination of these suspended sediments in the water column cause turbidity plumes during storm events which can extend beyond the canal and degrade water quality within the nearshore marine environment. Predicting how far turbidity plumes could extend during a storm event is difficult and can in turn make it difficult to predict where impacts to the nearshore marine environment could occur. However, PacIOOS has developed a turbidity plume forecast model for the Ala Wai Canal allowing the tracking of potential turbidity levels and extent of turbidity plumes along the nearshore marine environment. As an example of how a turbidity plume might extend out of the Ala Wai Small Boat Harbor and into the nearshore marine environment, PacIOOS conducted a model run of a turbidity plume for a storm event that occurred December 25 through December 27, 2017, in the Honolulu area. Figure 23 shows selected time progressions of this storm's modeled turbidity plume.

As seen in Figure 23, at the beginning of the storm event (i.e., December 25; 23:00 HST) the Ala Wai Canal begins to experience high turbidity with low turbidity beginning to occur within the Ala Wai Small Boat Harbor. Following approximately 12 hours (i.e., December 26, 2017; 12:00 HST), high turbidity is experienced throughout Ala Wai Canal and Ala Wai Small Boat Harbor, while low to medium turbidity is beginning to occur along the reef flat area outside of Ala Wai Harbor and within the vicinity of the Atlantis Submarines harbor. Following the passage of another 12 hours (i.e., December 26, 2017; 23:00 HST), high turbidity continues to be experienced throughout the Ala Wai Canal, but high turbidity within the Ala Wai Boat Harbor is beginning to dissipate. Similarly, medium turbidity is still being experienced within the vicinity of the Atlantis Submarines Harbor and low turbidity is being experienced along the nearshore marine area (reef flat)—within the vicinity of the Sheraton Hotel on Waikiki. Following the

passage of another 6 hours (i.e., December 27, 201; 06:00 HST), the turbidity plume begins to dissipate along the nearshore marine area, although low turbidity is still being experienced. Turbidity within the Ala Wai Boat Harbor has also begun to dissipate currently with moderate turbidity occurring in the harbor. Over the course of the following 18 hours, from 12:00 HST to 23:00 HST on December 27, 2017, the turbidity plume further dissipates, although low/medium turbidity is still being experienced within the Ala Wai Boat Harbor and the harbor channel. In addition, the Ala Wai Canal is experiencing medium turbidity still after approximately 48 hours has passed from the beginning of the storm event. The above details a potential turbidity plume under the future without project condition. This means that even under the future without project condition, marine habitat located within Ala Wai Harbor generally experiences high turbidity during a storm event while marine habitat located outside the Ala Wai Boat Harbor and along Waikiki Beach experiences medium to low turbidity during a storm event.

During a storm event under the future without project condition, marine habitat in the harbor (Ala Wai Small Boat Harbor and Atlantis Submarines Harbor), reef flat (adjacent to Ala Wai Small Boat Harbor), reef crest (near Ala Wai Small Boat Harbor), fore reef (near Ala Wai Small Boat Harbor), and bank/shelf (near Ala Wai Small Boat Harbor) zones experiences medium to high turbidity for approximately 24 hours (depending on the size of the storm event) before turbidity begins to dissipate. Low turbidity during this same time occurs in the shoreline intertidal and reef flat zones between the Atlantis Submarines Harbor and the Sheraton Hotel in Waikiki. Between approximately 24 and 48 hours (depending on the size of the storm event) following a storm event, turbidity within the harbor zone has been reduced to medium levels while turbidity along shoreline intertidal, reef flat, reef crest, fore reef, and bank/shelf zones has been reduced to low or clear levels.

Under the proposed project, turbidity plumes occurring during a storm event could carry higher sediment and nutrient concentrations and take additional time to dissipate upon reaching the nearshore marine environment. Therefore, medium to high turbidity levels could be experienced at the harbor, reef flat, reef crest, fore reef, and bank/shelf zones sooner than under the without project condition. Turbidity plumes extending into the nearshore marine environment may also take longer than approximately 24 hours for dissipation to begin. Elevated turbidity and sedimentation may impact hawksbill sea turtle. However, given that hawksbill sea turtles breathe air instead of water, increased turbidity should not adversely affect their respiration or other biological function.

Although BMPs are not defined for operation of the proposed project, the project does include a detention basin at the Ala Wai Golf Course that would collect storm water runoff from the Manoa-Palolo Canal, detain the runoff, and slowly release the runoff back into the Ala Wai Canal. The operation of the detention basin in conjunction with the floodwalls could minimize potential indirect impacts to marine habitat utilized by hawksbill sea turtle from acceleration of the delivery of storm water runoff to the nearshore marine environment and the quality of storm water runoff reaching the nearshore marine environment. This is because storm water runoff from the Manoa-Palolo canal would be held within the detention basin for up to two days providing time for some sediments entrained within the water column to settle out in the detention basin. After approximately two days, the detained storm water runoff would begin to slowly be released back into the Ala Wai Canal. Sediment retained in the detention basin would then be collected and disposed of at an appropriate facility. With the operation of the detention basin, a negligible or no change to the sediment/nutrient concentration of the storm water runoff reaching the nearshore marine environment could occur. Most of the sediment containing excess nutrients and legacy contaminants comes from the Manoa and Palolo streams which feed into the Manoa-Palolo Canal. Therefore, the operation of the detention basin—which would

hold storm water runoff from these streams during a storm event and provide time for sedimentation to occur—has the potential to avoid or minimize the possible impact of the proposed project on increased nutrient and sediment loading to the nearshore marine environment. The operation of the detention basin could also help avoid and minimize the potential impact of the proposed project on accelerated discharge of freshwater to the nearshore marine environment.

Exposure to wastes and discharges:
Although construction of the proposed action primarily occurs upland, construction activities are often located adjacent to the aquatic environment. Therefore, construction waste may end up in the aquatic environment if not properly disposed of. Construction wastes may include plastic trash and bags that may be ingested and cause digestive blockage or suffocation, or if large enough, along with discarded sections of ropes and lines, may entangle hawksbill sea turtle. Equipment spills and discharges likely consist of hydrocarbon-based chemicals such as fuel oils, gasoline, lubricants, hydraulic fluids, and other toxicants, which could expose hawksbill sea turtle to toxic chemicals. Depending on the chemicals and their concentration, exposure could result in a range of effects, from avoidance of an area to death. Local and Federal regulations prohibit the intentional discharge of toxic wastes and plastics into the marine environment. In addition, BMPs listed under environmental commitments, located further below in this section, include measures intended to prevent or reduce exposure of hawksbill sea turtle to wastes and discharges in the marine environment.

Loss of forage habitat:
Short-term, the loss of forage habitat could occur with the upgrading/modification of stormwater drainage structures which has the potential to be in habitat where hawksbill sea turtle may forage. The upgrading/modification of drainage structures includes the temporary placement of cofferdam materials within the Ala Wai Canal which may impact forage species through damage or destruction. At the level of the individual, the loss of significant levels of available forage may lead to lower growth rates, reduced fitness, reduced reproductive success, and potential death by starvation. At the population level, significantly reduced forage opportunities may eventually cause local extirpation through the death or emigration of members of that population.

The upgrading and/or modification of stormwater drainage structures would occur from upland if the structure were located above the water level of the canal. If the stormwater drainage structure is located at water level or below water level a cofferdam would need to be constructed so that upgrading and/or modification of the drainage structure could occur in the dry. The placement of cofferdam material would occupy the smallest footprint possible, therefore, limited in-water substrate disturbance is anticipated to occur. Once upgrading/modification of the drainage structure is complete the cofferdam would be removed in its entirety. Therefore, the loss of potential forage habitat located within the cofferdam footprint would be temporary because epibenthic life would likely re-colonize the area once the structure is removed.

Long-term, the operation of the proposed action could cause sediment mobilization that has the potential to smother forage resources. An increase in suspended sediments during a storm event, above that experienced under the future without project condition, would likely result in increased deposition rates within the canal and nearshore marine areas. According to the Ala Wai Canal Watershed Water Quality Improvement Project (City and County of Honolulu, 1998), sedimentation in the Ala Wai Canal occurs at the rate of about 10,300 CY per year. Sedimentation is also prevalent in the Manoa-Palolo Canal which receives the first flush from storm waters. Increased sedimentation in nearshore marine waters could smother hawksbill sea

turtle foraging habitat. Although the proposed project is expected to potentially increase sediment delivery to the nearshore marine environment, the degree of increase is not expected to be substantially different from the existing condition; therefore, hawksbill sea turtle foraging habitat in the action area is not expected to substantially decrease from its current abundance within the action area.

Although BMPs are not defined for operation of the proposed project, the project does include a detention basin at the Ala Wai Golf Course that would collect storm water runoff from the Manoa-Palolo Canal, detain the runoff, and slowly release the runoff back into the Ala Wai Canal. The operation of the detention basin in conjunction with the floodwalls could minimize potential indirect impacts to hawksbill sea turtle foraging habitat from acceleration of the delivery of storm water runoff to the nearshore marine environment and the quality of storm water runoff reaching the nearshore marine environment. This is because storm water runoff from the Manoa-Palolo canal would be held within the detention basin for up to two days providing time for some sediments entrained within the water column to settle out in the detention basin. After approximately two days, the detained storm water runoff would begin to slowly be released back into the Ala Wai Canal. Sediment retained in the detention basin would then be collected and disposed of at an appropriate facility. With the operation of the detention basin, a negligible or no change to the sediment/nutrient concentration of the storm water runoff reaching the nearshore marine environment could occur and in turn minimize the potential impact on hawksbill sea turtle foraging habitat within the nearshore marine environment. Most of the sediment containing excess nutrients and legacy contaminants comes from the Manoa and Palolo streams which feed into the Manoa-Palolo Canal. Therefore, the operation of the detention basin—which would hold storm water runoff from these streams during a storm event and provide time for sedimentation to occur—has the potential to avoid or minimize the possible impact of the proposed project on increased nutrient and sediment loading to the nearshore marine environment and thereby minimize the potential for resulting habitat degradation of hawksbill sea turtle foraging habitat.

Overall, the proposed action involves minor in-water work which could expose hawksbill sea turtle to project-related activity. However, with the implementation of avoidance and minimization measures listed under environmental commitments, located further below in this section, potential impacts to hawksbill sea turtle due to project-related activity is expected to be minimized such that the proposed action may affect, but is not likely to adversely affect hawksbill sea turtle.

Essential Fish Habitat

Pursuant to the Magnuson-Stevens Act, an adverse effect is defined as any impact that reduces quality and/or quantity of EFH; this includes direct or indirect physical, chemical, or biological alterations of the waters or substrate and loss of, or injury to species and their habitat, and other ecosystem components.

As described in Section 3.4.5, no portion of the proposed alternative action area has been designated as EFH, such that the proposed project is not expected to directly affect the quality and/or quantity of EFH. The nearshore waters downstream from the Ala Wai Canal (i.e., Ala Wai Small Boat Harbor, Mamala Bay, etc.) include EFH for various lifestages of bottomfish, pelagics, and crustaceans. In general, conditions that could indirectly affect EFH include increased delivery of sediment and associated contaminants, which could smother bottom substrate and degrade water quality. However, as described in Section 3.3.4, the proposed project is not expected to result in significant water quality impacts, either within the streams or nearshore waters (including EFH). Rather, it is possible that some degree of benefit could be realized over

the long-term through the capture and removal of sediment from the three proposed detention basins. As such, the proposed project is not expected to adversely affect EFH, either directly or indirectly.

Refer to Appendix K for the EFH analysis and the USACE's determination that the proposed project would have no adverse effect on EFH.

Conservation Plan(s)
There are no HCPs in place within the proposed alternative action area, therefore, the project would have no direct or indirect effects on implemented HCPs.

Alternative 5.3

Less than Significant Impact with Environmental Commitments Incorporated: In general, the type of project features included in Alternative 5.3 would have similar construction, operation, maintenance, and mitigation requirements as Alternative 1 and Alternative 2B, such that the nature and degree of potential impacts to biological resources within the alternative action area are generally expected to be similar. However, for comparison, the amount of acreage temporarily and permanently impacted under Alternative 5.3 is found below in Table 41.

Table 41: Summary of Disturbance Ares for Alternative 5.3 Measures.

Structural Feature	Total Construction Area (acres)	Permanent Footprint (acres)	Vegetation Management Area for O&M (acres)	Inundation Area During Flood (acres)
Woodlawn Drive Floodwall	2.40	1.27	1.27	NA
Koali Road Floodwall	5.00	2.47	2.47	NA
Ala Wai Golf Course Detention Basin	35.79	181.20	181.20	156.03
Ala Wai Canal Floodwall	42.17	23.30	23.30	NA
TOTAL	**85.36**	**208.24**	**208.24**	**156.03**

Alternative 6

Less than Significant Impact: Negligible long-term and negligible to minor short-term direct impacts to plant communities are expected to result from implementation of Alternative 6, because land disturbance for this alternative would be limited to modification of existing buildings and land disturbance in their immediate vicinity. Implementation of Alternative 6 would require construction access to all structures to be treated which would be expected to occur from existing roads. Similarly, localized maintenance such as repairs would be needed over time.

Negligible to minor short-term indirect adverse impacts to wildlife species are expected to result from implementation of Alternative 6, because land disturbance for this alternative would be limited to modification of existing buildings. Animal species would likely avoid the area during construction. Implementation of Alternative 6 would require temporary construction access to all structures to be treated; this would be expected to occur from existing roads. Similarly, localized

maintenance such as repairs will be needed over time. Overall, negligible to minor long-term indirect effects to wildlife species are expected as a result of future maintenance activities.

No aquatic communities or habitat will be impacted by the implementation of Alternative 6, therefore no short-term or long-term direct or indirect adverse effects to aquatic communities would occur.

Negligible to minor short-term or long-term adverse effects to threatened and endangered species are expected to result from implementation of Alternative 6, because land disturbance for this alternative would be limited to modification of existing buildings. There would be temporary land disturbance in yards and impervious surfaces surrounding the existing buildings; however, no new undeveloped habitats would be impacted. Implementation of Alternative 6 would require construction access to all structures to be treated, but this would be expected to occur from existing roads. Similarly, localized maintenance such as repairs will be needed over time.

Environmental Commitments

The following environmental commitments would be implemented by the contractor during construction activities to avoid and minimize potential impacts to biological resources.

EC BR-1: The following environmental commitments are designed to avoid or minimize impacts to fish and wildlife resources, and ESA-listed marine resources:

- Authorized filling-related activities that may result in the temporary or permanent loss of aquatic habitats should be designed to avoid indirect, negative impacts to aquatic habitats beyond the planned project footprint.
- Turbidity and siltation from project-related work should be minimized and contained within the project footprint by silt containment devices and curtailing work during flooding or adverse tidal and weather conditions. BMPs should be maintained for the life of the construction period until turbidity and siltation within the project footprint is stabilized. All project construction-related debris and sediment containment devices should be removed and disposed of at an approved site.
- All project construction-related materials and equipment (dredges, vessels, backhoes, silt curtains, etc.) to be placed in an aquatic environment should be inspected for pollutants including, but not limited to; marine fouling organisms, grease, oil, etc., and cleaned to remove pollutants prior to use. Project related activities should not result in any debris disposal, non-native species introductions, or attraction of non-native pests to the affected or adjacent aquatic or terrestrial habitats. Implementing both a littler-control plan and a Hazard Analysis and Critical Control Point plan (HACCP – see https://www.fws.gov/policy/A1750fwl.html) can help to prevent attraction and introduction of non-native species.
- Project construction-related materials (fill, revetment rock, pipe, etc.) should not be stockpiled in, or in close proximity to aquatic habitats and should be protected from erosion (e.g., filter fabric, etc.), to prevent materials from being carried into waters by wind, rain, or high surf.
- Fueling of project-related vehicles and equipment should take place away from the aquatic environment and a contingency plan to control petroleum products accidentally spilled during the project should be

developed. The plan should be retained on site with the person responsible for compliance with the plan. Absorbent pads and containment booms should be stored on-site to facilitate the clean-up of accidental petroleum releases.

- All deliberately exposed soil or under-layer materials used in the project near water should be protected from erosion and stabilized as soon as possible with geotextile, filter fabric, or native or non-invasive vegetation matting, hydro-seeding, etc.

EC BR-2: The following environmental commitments are designed to avoid and minimize potential project impacts to Hawaiian hoary bat:

- Do not disturb, remove, or trim woody plants greater than 15 feet tall during the bat birthing and pup rearing season (June 1 through September 15).
- Do not use barbed wire for fencing.

EC BR-3: The following environmental commitments are designed to avoid and minimize potential project impacts to Hawaiian seabirds:

- To the maximum extent practicable, limit construction activities to the time between dawn and dusk to avoid the illumination of adjacent habitat areas.
- If construction activity time restrictions are not possible, use down shielding or directional lighting to avoid light trespass into bird habitat (i.e., use a 'Cobra' style light rather than an omnidirectional light system to direct light down to the roadbed). To the maximum extent practicable, while allowing for public safety, low intensity energy saving lighting (e.g., low pressure sodium lamps) will be used.
- Minimize illumination of lighting on associated construction or operation structures by using motion sensors or heat sensors.
- Bright white light, such as metal halide, halogen, fluorescent, mercury vapor, and incandescent lamps should not be used.
- Fully shield all outdoor lights so the bulb can only be seen from below bulb height and only use when necessary.
- Install automatic motion sensor switches and controls on all outdoor lights or turn off lights when human activity is not occurring in the lighted area.
- Avoid nighttime construction during the seabird fledgling period, September 15 through December 15.

EC BR-4: The following environmental commitments are designed to avoid and minimize potential project impacts to Hawaiian waterbirds:

- In areas where waterbirds are known to be present, reduced speed limit signs will be posted to inform project personnel and contractors about the presence of endangered species on—site; and reduced speed limits will be implemented.
- Applicable USFWS BMPs regarding work in aquatic environments will be incorporated and implemented into the project design if water resources are located within or adjacent to the project footprint in order to contain stream sediments to the operational area.
- A biological monitor that is familiar with Hawaiian waterbirds' biology will conduct nest surveys where appropriate habitat occurs within the vicinity

of the proposed project footprint prior to project initiation. Surveys will be repeated within three days of project initiation and after any subsequent delay of work of 3 or more days (during which the birds may attempt to nest). If a nest or active brood is found:

- The USFWS will be contacted within 48 hours for further guidance.
- A 100-foot buffer will be established and maintained around all active nests and or broods until the chicks have fledged. Potentially disruptive activities will not be conducted, and habitat alteration will not occur within this buffer.
- A biological monitor that is familiar with the species' biology will be present on the project footprint during all construction or earth moving activities until the chicks fledge to ensure that Hawaiian waterbirds and nests are not adversely impacted.

EC BR-5 The following environmental commitments are designed to avoid and minimize potential project impacts to green sea turtle, hawksbill sea turtle, and Hawaiian monk seal:

- Constant vigilance shall be kept for the presence of ESA-listed marine species during all aspects of the proposed action, particularly in-water activities.
- The USACE shall designate an appropriate number of competent trained observers to survey the areas adjacent to the proposed action for ESA-listed marine species.
- Surveys shall be made prior to the start of work each day, and prior to resumption of work following any break of more than one-half hour. Periodic additional surveys throughout the workday are strongly recommended.
    - Special attention will be given to verify that no ESA-listed species are in the area where equipment or material is expected to enter the water where there is a risk of contact with the species.
    - Certain activities may require additional surveys as advised by NMFS on an *ad hoc* basis as identified during the consultation.
- All work shall be postponed or halted when motile ESA-listed marine species are within 164 feet (50 meters) of the proposed work and shall only begin/resume after the animals have voluntarily departed the area.
    - If ESA-listed motile marine species are noticed within 164 feet (50 meters) after work has already begun, that work may continue only if the activity will not adversely affect the animal(s). For example, divers performing underwater work such as monitoring or surveys would likely be permissible, whereas operation of heavy equipment is likely not.
- All objects will be lowered to the bottom (or installed) in a controlled manner to avoid contact with ESA-listed species. This can include the use of buoyancy controls such as lift bags, or the use of cranes, winches, or other equipment that affect positive control over the rate of descent.
- Do not attempt to feed, touch, ride, or otherwise intentionally interact with any ESA-listed marine species.

- Report any monk seal sightings:
    - Email NMFS at pifsc.monksealsighting@noaa.gov
    - Call the Marine Animal Stranding, Entanglement, and Reporting Hotline at: 888-256-9840.
- No contamination of the marine environment shall result from project-related activities.
- A contingency plan to control toxic materials is required.
- Appropriate materials to contain and clean potential spills shall be stored at the work site and be readily available.
- Heavy equipment in and near water bodies shall consider the use of biofuels and non-petroleum-based hydraulic fluids.
- All project-related materials and equipment placed in the water shall be free of pollutants.
- The contractor and heavy equipment operators shall perform daily pre-work equipment inspections for cleanliness and leaks. All heavy equipment operations shall be postponed or halted should a leak be detected and shall not proceed until the leak is repaired and equipment cleaned.
- Fueling of land-based vehicles and equipment shall take place at least 164 feet (50 meters) away from the water, preferably over an impervious surface.
- Turbidity and siltation from project-related work shall be minimized and contained through the appropriate use of erosion control practices, effective silt containment devices, and the curtailment of work during adverse weather and tidal/flow conditions.
- A plan shall be developed to prevent debris and other wastes from entering or remaining in the marine environment during the project.
- All work shall be postponed or halted when motile ESA-listed marine species are within 164 feet (50 meters) of the proposed work and shall only begin/resume after the animals have voluntarily departed the area.
- Minimize direct contact to corals, seagrass, or other sessile ESA-listed resources.
- All work shall be postponed or halted when motile ESA-listed marine species are within 164 feet (50 meters) of the proposed work and shall only begin/resume after the animals have voluntarily departed the area.
- Unauthorized Take – If a listed marine mammal is determined by the PSO to have been disturbed, harassed, harmed, injured, or killed (e.g., a listed marine mammal(s) is injured or killed or is observed entering a shutdown zone before operations can be shutdown), it will be reported to NMFS within one business day to Ron.Dean@noaa.gov. These PSO records, submitted in digital and guervable format to NMFS, will include:
    - Information to be provided in the final report;
    - Number and species of listed animals affected;
    - The date, time, and location of each event (provide geographic coordinates);
    - Description of the event;
    - The time the animal(s) was first observed or entered the shutdown zone, and, if known, the time the animal was last seen or exited the zone, and the fate of the animal;
    - Mitigation measures implemented prior to and after the animal was taken;

    - If a vessel struck a marine mammal, the contact information for the PSO on duty, or the contact information for the individual piloting the vessel if there was no PSO on duty;
    - Photographs or video footage of the animal(s) (if available).
- Stranded, injured, sick, or dead marine mammal (not associated with the project);
    - If PSOs observe an injured, sick, or dead marine mammal (i.e., stranded marine mammal), they will notify the Pacific Islands Marine Mammal Stranding Hotline at 888-256-9840. The PSOs will submit photos and data that will aid NMFS in determining how to respond to the stranded animal. Data submitted to NMFS in response to stranded marine mammals will include date/time, location of stranded marine mammal, species and number of stranded mammals, description of the stranded marine mammal's condition, event type (e.g., entanglement, dead, floating), and behavior of live-stranded marine mammals.
- All areas of temporary waterway or wetland fill will be restored to their original contour and character upon completion of the project. Temporary fil includes both fill that received authorization and fill that inadvertently enters a water of the U.S. (i.e., from slope failures, accidental broken sandbag cofferdams, etc.). All temporary fills and structures in waters of the U.S. will be removed in their entirety upon completion of use. This avoidance and minimization measure will ensure restoration of flow to waterbodies for fish migration and avoids creation of potential sources of sedimentation and erosion that may elevate turbidity and adversely impair water quality conditions of downstream waters where federally listed marine species may occur.
- All in-water excavation will be conducted within a cofferdam or other sediment containment device extending from the water surface to the substrate intended to isolate and contain in the work area. All in-water sediment containment devices will be placed to isolate the minimum area necessary to complete the work and will be removed upon completion of in-water work only after the water quality in the enclosed area has returned to ambient and would not release a turbidity plume. This avoidance and minimization measure isolates and contains sediments to the in-water work area and reduces potential for adverse impairment of water quality conditions with the rick of degrading water quality conditions of downstream waters where federally listed marine species may approach the in-water work area (I.e., Ala Wai Canal), the sediment containment device will create a physical barrier preventing interaction and potentially physical impact to federally listed marine species.
- All upland areas of disturbed soil will be mulched and seeded with an approved native or noninvasive herbaceous seed mix following construction and/or planted with native or noninvasive woody vegetation and trees appropriate during the first available planting season. In areas where there is little to no slope and erosion and invasive species establishment is unlikely, the native woody vegetation on the site will be allowed to regenerate naturally. This avoidance and minimization measure avoids creation of potential sources of sedimentation and erosion that may elevate turbidity and adversely impact water quality

conditions of downstream waters where federally listed marine species may occur.

- Temporary access roads placed in the riparian area will be constructed in a manner that they do not allow erosion into waters of the U.S. during construction. This avoidance and minimization measure avoids creation of potential sources of sedimentation and erosion that may elevate turbidity and adversely impair water quality conditions of downstream waters where federally listed marine species may occur.
- All off-road equipment and vehicles operation from existing open and maintained roads must be cleaned prior to entering the construction site to remove all soil, seeds, vegetation, or other debris that could contain seeds or reproductive portions of plants. All equipment will be inspected prior to off-loading to ensure that they are clean. This avoidance and minimization measure minimizes the spread of invasive plants that may degrade riparian habitats and erode sediments, resulting in reduced water quality conditions that may negatively affect green and hawksbill sea turtles and the Hawaiian monk seal.
- During construction, any disturbed soils will be temporarily stabilized with materials such as hay, mulch, plastic sheeting, erosion control mix, or other appropriate measures. This avoidance and minimization measure reduces the risk of erosion and exposure to reduced water quality conditions that may otherwise negatively affect green and hawksbill sea turtles and the Hawaiian monk seal.
- Cofferdam materials will be fully removed from the stream immediately following completion of in-water work, minimizing delays due to high stream flows following heavy precipitation. All areas of temporary bottom disturbance will be restored to their original contour and character upon completion of the project. This avoidance and minimization measure removes obstacles and barriers to fish passage and returns benthic habitat to its original composition, limiting sediment disturbance and the temporary effects of degraded water quality conditions to green and hawksbill sea turtles and the Hawaiian monk seal.
- All cofferdams will be removed using techniques to minimize turbidity releases. This includes allowing for the slow reintroduction of water into the work area and utilizing dirty water treatment systems for turbid water. This avoidance and minimization measure avoids degrading water quality conditions that may negatively affect green and hawksbill sea turtles and the Hawaiian monk seal.
- No equipment, materials, or machinery will be stored, cleaned, fueled, or repaired within any water of the U.S. All vehicle and equipment refueling activities will occur more than 100 feet from any water course and if not, all refueling areas will require fuel spill containment structures. A spill prevent and response plan will be prepared and implemented by the construction contractor. This avoidance and minimization measure avoids creation of a pollutant source that may degrade downstream water quality conditions where federally listed marine species may occur.
- All pumps and generators will have appropriate spill containment structures and/or spill remediation materials available, such as absorbent pads. This avoidance and minimization measure reduces the risk of

green and hawksbill sea turtle and Hawaiian monk seal exposure to petroleum products and other contaminants.

- All equipment used for in-stream work will be cleaned of external oil, grease, dirt, and mud such that turbid water does not enter any water of the U.S. Any leaks or accumulations of these materials will be correlated before entering streams of areas that drain directly to streams or wetlands. All releases into surface waters or wetlands will be reported immediately to the appropriate regulatory body. This avoidance and minimization measure reduces the risk of green and hawksbill sea turtles and the Hawaiian monk seal exposure to petroleum products and other contaminants.

Best Management Practices

No BMPS associated with impacts due to biological resources apply, although the environmental commitments listed above are similar to BMPs.

3.4.8 Agricultural and Forestry Resources

Regulatory Setting

Relevant federal and state laws/regulations include:

- Farmland Protection Policy Act

Existing Conditions

According to the United States Department of Agriculture (USDA, 2023) there are approximately 7,300 farms throughout the Hawaiian Islands. In addition, approximately 1,100 acres of land is in farms with the average farm size being approximately 151 acres. Following are the top 20 agricultural commodities produced by the State of Hawaii in 2021 (HDOA, 2022): seed crops, macadamia nuts, coffee, cattle, algae, basil, food crops grown under protection, potted orchids, eggs, papayas, lettuce, cabbage, taro, bananas, ornamental-aquaculture, potted palms, honey, green onions, sweet potatoes, and mushrooms. In addition to farms, Hawaii also has aquaculture production which includes the following overarching commodities: shellfish, finfish, algae, ornamental, and other (USDA, 2022).

Within the study area, there is no commercial agriculture for the most part. It is important to note that taro is grown along Manoa Stream near Dole Street. Ka Papa Loi O Kanewai sustains a taro patch that shares its resources with the surrounding community. Within the vicinity of the taro patch there are a variety of native and indigenous trees and shrubs growing along the stream and low-lying slopes. The Ka Papa Loi O Kanewai is part of the University of Hawaii at Manoa's School of Hawaiian Knowledge.

Regarding forestry, there are three timber management areas within the Hawaiian Islands. Timber management areas are State-owned lands designated for the sustainable production of forest products. Harvesting activities within the timber management areas need to follow a management plan approved by the Board of Land and Natural Resources and in accordance with the provisions regarding conservation of aquatic life, wildlife, and land plants, and with the provisions regarding environmental impact statements. The three active timber management areas in Hawaii currently are: Waiakea Timber Management Area, Kokee Timber Management Area, and Kapapala Canoe Forest Timber Management Area. None of these timber management areas are located on Oahu. However, the upper portion of Oahu is within a Conservation District. The Conservation District where forest is located is divided primarily into two subzones: protective and resource. Conservation District areas under the resource subzone

designation, sustainable commercial forestry can occur as long as it is conducted under an approved management plan and the necessary permit (Hawaii Administrative Rules, 13-5-24). Conservation District areas under the protective subzone designation, no commercial forestry is permitted (Hawaii Administrative Rules, 13-5-22).

Significance Criteria

Effects on agricultural and forestry resources would be considered significant if the proposed project would result in any of the following:

- Convert Prime Farmland, Unique Farmland, or Farmland of Statewide importance (Farmland) to non-agricultural uses.
- Result in the loss of forest land or conversion of forest land to non-forest use.

Environmental Consequences

No Action Alternative

Under the No Action Alternative, no project would be constructed. As a result, the No Action Alternative would not cause the conversion of prime, unique, or farmland of statewide importance to non-agricultural uses; or result in the loss of forest land or conversion of forest land to non-forest use.

Alternative 1

No Impact: Regarding farmland, the NRCS web soil survey was reviewed to determine which soils in the area are designated as prime farmland (Table). The Manoa Valley District Park detention basin, portions of the Woodlawn Drive floodwall, portions of the Ala Wai Golf Course floodwall, and the Ala Wai Canal floodwalls are located on soils that are not prime farmland. The Makiki District Park detention basin (including the Kanaha floodwall), portions of the Woodlawn Drive floodwall, Koali Road floodwall, Kaimuki High School floodwall, portions of the Ala Wai Golf Course, and portions of the Manoa-Palolo Canal are located on soils that are prime farmland if irrigated. None of these areas are farmland currently and they are not expected to be converted to farmland in the future. One known taro farm operated by the University of Hawaii at Manoa's School of Hawaiian Knowledge is located along Manoa Stream. Ka Papa Loi O Kanewai is located near Dole Street, approximately 800 feet upstream of Kanewai Community Park. No project features are located within the vicinity of Ka Papa Loi O Kanewai, although the staging area for construction of the Koali Road Floodwall is located within Kanewai Community Park. No impacts to Ka Papa Loi O Kanewai during construction staging or project operation and maintenance are expected. Therefore, there would be no short-term or long-term impacts to prime farmland, unique farmland, or farmland of statewide importance due to implementation of the project.

Areas that are primarily forested within the watershed are located in the upper part of the watershed that has been designated as Conservation District. None of the project measures are located within the Conservation District.

Alternative 1 also requires potential mitigation measures to minimize induced flooding within the watershed. Potential nonstructural mitigation measures that are being considered include dry/wet floodproofing, elevation, and acquisition. These measures are similar to those proposed under the Nonstructural Alternative, therefore, refer to Alternative 6 below for the analysis of potential effects to agriculture and/or forestry resources. The only potential structural mitigation measure under consideration is a pump station(s), although due to the cost of construction the inclusion of this as a mitigation measure is highly unlikely. However, the potential impacts of a pump station(s) are assessed. Although the precise location of the pump station(s) is unknown

at this time, it is likely that if selected as a mitigation measure it would need to be constructed along Makiki Stream between Fern Street and the confluence of Makiki with the Ala Wai Canal. In this general area there are no existing farmlands, and the general area is not expected to be converted to farmland in the future. Similarly, there are no forested areas within the general area where a pump station(s) may be constructed. Therefore, the proposed project would have no short-term or long-term impacts to forest land or prime farmland, unique farmland, or farmland of statewide importance.

Alternative 2B

No Impact: In general, the type of project features included in Alternative 2B would have similar construction, operation, maintenance, and mitigation requirements as Alternative 1, such that the nature and degree of potential impacts to agricultural and forestry resources are generally expected to be similar. Therefore, refer to the analysis under Alternative 1 for Alternative 2B project impacts. Overall, the proposed project would have no short-term or long-term impacts to forest land or prime farmland, unique farmland, or farmland of statewide importance.

Alternative 5

No Impact: In general, the type of project features included in Alternative 5 would have similar construction, operation, maintenance, and mitigation requirements as Alternative 1 and Alternative 2B, such that the nature and degree of potential impacts to agricultural and forestry resources are generally expected to be similar. Therefore, refer to the analysis under Alternative 1 and Alternative 2B for Alternative 5 project impacts. Overall, the proposed project would have no short-term or long-term impacts to forest land or prime farmland, unique farmland, or farmland of statewide importance.

Alternative 6

No Impact: The implementation of Alternative 6 would have no short-term or long-term direct or indirect adverse effects to agricultural or forestry resources because the alternative includes construction on existing structures only. Temporary construction access would be required but this is expected to occur from existing roads. Overall, the proposed project would have no short-term or long-term impacts to forest land or prime farmland, unique farmland, or farmland of statewide importance.

Environmental Commitments

No environmental commitments would be implemented since there would be no impacts to agricultural or forestry resources.

Best Management Practices

No BMPs would be implemented since there would be no impacts associated to agricultural or forestry resources.

3.5 Built Environment

3.5.1 Cultural Resources

Regulatory Setting

Relevant federal and state laws/regulations include:

- National Historic Preservation Act (NHPA)
- American Indian Religious Freedom Act (AIRFA)

- Historic Preservation Law (Chapter 6E, Hawaii Revised Statutes (HRS))
- Hawaii Environmental Protection Act (HEPA) (Chapter 343, Hawaii Revised Statutes)

The most important of these laws and regulations for the evaluation of impacts to cultural resources are NHPA, HRS Chapter 6E, and HEPA. HRS Chapter 6E consultation will be undertaken by the non-federal sponsor at an appropriate point in the design development process. Although the outcome of 6E consultation should be concordant with that of NHPA Section 106 consultation at the Federal level, it may potentially generate additional impact findings and mitigation requirements beyond what is contained in this section. NHPA compliance for the project is presently guided by an executed Programmatic Agreement (PA). However, if the PA's applicability period is not extended prior to project execution, NHPA Section 106 consultation will need to be re-initiated and a new PA developed with consulting parties. Re-initiation of consultation would be most productive at around the 35% design stage, although earlier coordination with the Hawaii State Historic Preservation Officer is recommended to help generate a design which minimizes impacts. Finally, HEPA compliance includes a requirement to evaluate the effects of a project on cultural beliefs, practices, and resources through the completion of a Cultural Impact Assessment (CIA) study. A CIA study was completed in 2014 for an earlier iteration of the Ala Wai project design. Updates to that CIA, and evaluation of its applicability to the current design, will be the responsibility of the non-federal sponsor, to be undertaken at an appropriate stage in the design development process.

Existing Conditions

Cultural and historic resources for the Ala Wai watershed were originally evaluated in the context of a National Historic Preservation Act PA signed in 2016 by the U.S. Army Corps of Engineers, the Hawaii State Historic Preservation Office, the State of Hawaii Department of Land and Natural Resources, the Oahu Island Burial Council, the Office of Hawaiian Affairs, and Historic Hawaii Foundation. The PA contains ten major stipulation categories, each with numerous subsections, which detail a procedure to be utilized to evaluate project effects and determine appropriate and mutually agreeable mitigation and treatment approaches for known or inadvertently discovered historic properties. The Ala Wai PA was fully executed on November 16, 2016, and remains in effect for a period of seven years.

Numerous technical studies were conducted to support the development of the 2016 PA and to identify cultural and historic resources within the Ala Wai watershed. These studies include:

- *Cultural Resources and Ethnographic Study for the Ala Wai Watershed Project: Makiki, Mānoa and Pālolo Ahupuaʻa, Honolulu District, Oʻahu Island, TMK: [1] 2-3, 2-4, 2-5, 2-6, 2-7, 2-8, and 2-9; [1] 3-1, 3-2, 3-3, and 3-4, Volume I: Cultural Resources of the Makiki, Mānoa and Pālolo Ahupuaʻa, prepared for CH2M Hill, prepared by Cultural Surveys Hawaii, Inc., April 2010.*
- *Cultural Resources and Ethnographic Study for the Ala Wai Watershed Project: Makiki, Mānoa and Pālolo Ahupuaʻa, Honolulu District, Oʻahu Island, TMK: [1] 2-3, 2-4, 2-5, 2-6, 2-7, 2-8, and 2-9; [1] 3-1, 3-2, 3-3, and 3-4, Volume II: Cultural Resources of Kakaʻako and Waikīkī Ahupuaʻa, prepared for CH2M Hill, prepared by Cultural Surveys Hawaii, Inc., April 2010.*
- *Cultural Resources and Ethnographic Study for the Ala Wai Watershed Project, Honolulu, Makiki, Mānoa, Pālolo, and Waikīkī Ahupuaʻa, Honolulu District, Oʻahu Island, TMK: [1] 2-3, 2-4, 2-5, 2-6, 2-7, 2-8, and 2-9; [1] 3-1, 3-2, 3-3, and 3-4, Volume III:*

Ethnographic Study, prepared for CH2M Hill, prepared by Cultural Surveys Hawaii, Inc., April 2010.

- *Cultural Impact Assessment for the Ala Wai Canal Project, Waikīkī, Pālolo, Makiki, and Mānoa Ahupua'a, Honolulu (Kona) District, O'ahu, TMKs: [1] 2-3, 2-4, 2-5, 2-6, 2-7, 2-8, and 2-9; [1] 3-1, 3-2, 3-3, and 3-4, prepared for CH2M Hill, prepared by Cultural Surveys Hawaii, Inc., July 2014.*
- *Synthesis and Summary of Cultural Resource Assessments for the Makiki, Mānoa, and Pālolo Watersheds in Support of the Ala Wai Restoration Project Oahu, Hawaii. Cultural Surveys Hawaii, Inc., 2004.*
- *Historic Structures Inventory Survey of the Ala Wai Watershed, Prepared by Mason Architects, Inc. for CH2M HILL, 2010.*

Archaeological Resources

As part of the assessment of archaeological resources within the Ala Wai watershed for the 2017 Ala Wai Canal Flood Risk Management EIS, archival research was conducted to identify the background history, *wahi pana* (place names), *mo'olelo* (traditional stories), and previously recorded archaeological sites within the watershed. Specifically, the archival research included a review of previous archaeological studies, cultural history documents, historic maps and photographs, and Land Commission Awards (LCAs). This information was compiled and used to identify potential localities within the watershed where archaeological resources may exist, and the type and potential significance of those resources. In addition, a field investigation was conducted as part of the 2017 Ala Wai Canal Flood Risk Management EIS to identify additional surface archaeological features. It is important to note that an archaeological survey has not been conducted throughout the entirety of the Area of Potential Effect (APE). Instead, provisions for additional archaeological surveys, if needed, are in the 2016 PA. Additional discussion of the various resources is contained in the *Cultural Resources and Ethnographic Study for the Ala Wai Watershed Project, Vol I and II* (Cultural Surveys Hawaii, 2010).

Historic Structures

A historic structures inventory survey was conducted in 2010 for the Ala Wai watershed to inform analysis in the 2017 Ala Wai Canal Flood Risk Management EIS. The inventory identified a variety of structures dating from 1965 or earlier, including bridges, culverts, channel modifications, dams, and water supply structures. A detailed description of the various structures is contained in the *Historic Structures Inventory for the Ala Wai Watershed* (Mason Architects, 2010).

Traditional Cultural Uses and Practices

An ethnographic survey was conducted for the 2017 Ala Wai Canal Flood Risk Management EIS to evaluate potential "intangible" cultural resources, such as Traditional Cultural Places and places of traditional cultural and religious importance (Vogler et al., 2010). The survey area included the entire Ala Wai watershed.

Several themes emerged during the interviews for the survey, including those related to education and natural resource protection. Education was identified as an important component of fostering an appreciation for natural resources and preserving watershed resources. The participants described the extensive *lo'i* (irrigated agricultural terraces) that were once present within the watershed, noting that *lo'i* could serve as a valuable tool for teaching younger generations about traditional Hawaiian practices, as well as providing natural filtration and improving water quality. They described the role of agriculture within the community, explaining

the value of living off natural resources as part of the traditional Hawaiian culture, and protecting the land as a source of life.

Relative to flood risk management, the participants discussed the importance of keeping the streams clean (e.g., through community efforts) to maintain channel capacity. The transcripts and a more detailed summary of the interviews are contained in the *Cultural Resources and Ethnographic Study for the Ala Wai Watershed Project, Vol III* (Cultural Surveys Hawaii, 2010).

Additional relevant research was later conducted in the form of a Cultural Impact Assessment (CH2M Hill, 2014). Although CIAs are not specifically designed to identify sites of traditional and religious significance, such sites are commonly a product of CIA research due to their association with historic and current cultural practices. During the interviews associated with the CIA, information provided included specific references to activities and resources provided by the waterways in the study area. Relative to stream-based activities, many of the participants recalled swimming in the streams during their childhood; this included two deep ponds downstream of Woodlawn Bridge and areas along Pālolo Stream. They also discussed various forms of sustenance, including *o'opu*, crayfish, *'ōpae*, and *pipipi* collected from the streams, as well as fruits and other plants. The participants referenced multiple *lo'i* use to grow *kalo* (taro), including Ka Papa Lo'i o Kanewai and 'Aihualama Lo'i in Manoa. The interviewees also referenced other resources that were gathered, including *lava'e* in Palolo Valley, *la'au* in Manoa and Makiki Valleys, and *limu* along the shoreline. These resources were not only used for food consumption, but also for ceremonial purposes. Other stream-based resources identified included water used for ceremonial purposes and rocks used for multiple purposes (rock wall building, *imu* [underground oven] use, and pounding poi). The interviewees noted that the areas along the streams and waterways were inhabited by native Hawaiians and indicated the potential for encountering burials (particularly in the Waikiki area). As a result of these investigations for the 2017 Ala Wai Canal Flood Risk Management EIS, a variety of cultural resources were identified.

Significance Criteria

Effects on cultural resources would be considered significant if the proposed project would result in any of the following:

- Alter, directly or indirectly, any of the characteristics of a resource that qualifies it for the NRHP, or State Register of Historic Properties so that the integrity of the resource's location, design, setting, materials, workmanship, feeling, or association is diminished.
- Isolate cultural resources, practices, or beliefs from their setting (or otherwise limit access to areas that support those resources, practices or beliefs).
- Introduce elements that substantially alter the setting in which cultural resources, practices, or beliefs occur.
- Disturb any human remains, including those interred outside of formal cemeteries.

The Guidelines for Assessing Cultural Impacts, adopted by the Environmental Council in 1997 defines cultural practices and beliefs to include subsistence, commercial, residential, access-related, recreational, and spiritual, among other customs. Therefore, under HRS 343 and HAR 11-200, canoe paddling and their access to waterways may be considered a cultural practice. As such, during design, consultation and coordination will be done with canoe halau to mitigate and maintain accessibility to the canal. Canoe paddling is further discussed in Section 3.5.4 Recreation.

Environmental Consequences

No Action Alternative

No Impact: Under this alternative, no flood risk management features would be implemented by USACE. Historic properties that occur within the existing floodplain could be affected by future flood-related events (e.g., through inundation, scouring of the ground surface, or deposition of debris).

Alternative 1

Less than Significant Impact with Environmental Commitments Incorporated: Based on the studies conducted to date, it was determined that construction and operation of the project could impact historic properties within the Direct APE. Potential impacts include modifications that may affect the integrity and/or characteristic of historic properties. Table 42 lists the effect determination for each historic property identified within the Direct APE. For those properties with an adverse effect determination, treatment recommendations have been identified. The intent of these recommendations is to identify conditions that can be placed on the design and construction to mitigate impacts to the resource (EC CUL-1). Historic buildings, bridges, and walls affected by construction would undergo appropriate historic documentation, and design input would be solicited from SHPO and interested consulting parties and incorporated into the final design where feasible. Where possible, impacts to archaeological resources would be avoided. Where avoidance is not possible, data recovery would be performed. Where practicable, construction measures would be microsited either up or downstream to minimize the impacts to features of Native Hawaiian cultural significance (Traditional Cultural Property [TCPs]) that could be disturbed by project actions. Considering that the project is still in the feasibility phase and that there are still several unknown variables that may result in adverse effects through the future planning, design, and construction phases, a Programmatic Agreement was fully executed on November 16, 2016, and remains in effect for a period of seven years. The Programmatic Agreement establishes a process for further resource identification and effects determinations, resolving adverse effects, and expands upon the treatment recommendations listed in Table 42. The Programmatic Agreement was coordinated with the Advisory Council on Historic Preservation (ACHP), SHPO, and other consulting parties. A copy is included in Appendix L of this report. Implementation of the treatment recommendations developed through consultation and as per the Programmatic Agreement is expected to reduce potential impacts to a less than significant level.

Construction of floodwalls within the watershed could affect aesthetics within the watershed. Therefore, as per the Programmatic Agreement, design input to minimize visual impacts to the greatest extent possible will be solicited from SHPO and interested consulting parties, and incorporated, as feasible, into the final design and construction of floodwalls (EC CUL-2). Since there could be significant impact to visual aesthetics, floodwalls proposed under Alternative 1 include a lava rock façade on both sides of the floodwall to minimize visual impacts. With the implementation of environmental commitments EC CUL-1 and EC CUL-2, impacts to cultural resources are expected to be reduced to less than significant.

The CIA also identified a variety of cultural resources, practices, and beliefs that relate to the action area. These include gathering native plants and animals and other resources (e.g., water and rocks) from the streams. Overall, gathering of resources and other cultural practices that occur within and immediately adjacent to the alternative footprint may be temporarily disrupted during construction, as access within the various measure locations would likely be restricted during ground disturbing activities. However, the specific areas where the measures would be located are overwhelmingly dominated by non-native species; furthermore, there would still be

abundant opportunities to gather resources along streams throughout the upper watershed. Following construction, for the most part the implemented measures are not expected to limit access to cultural resources or practices. The potential exception is outrigger canoe access. There are four canoe launches along Ala Wai Canal that would require closure structures. These canoe launch closure structures would primarily be open and would only be closed for a period prior to a storm event, during a storm event, and for a period after the storm event until they can be reopened. Closing the canoe launch closure structures prior to a storm event and the opening of the closure structures post storm event would likely have the greatest impact by limiting access to cultural practices when they would have normally been able to occur under the current condition. However, closure of the canoe launch structures would likely occur within one or two days of a storm event occurring and would likely open within one or two days after the storm event has passed. Therefore, this is considered a temporary less than significant impact by limiting access to cultural practices. During the storm event it is unlikely that the canoe launch closure structures would have an impact on cultural practices because a storm event would typically cause boats to refrain from being launched into the water due to human safety concerns. Therefore, the canoe launch closure structures would have a temporary less than significant adverse impact to cultural practices.

There is a high possibility that ancestral bones may be present within the alternative footprint and that land-disturbing activities during construction may uncover presently undetected burials or other cultural materials. The Programmatic Agreement stipulates measures that the USACE will undertake to address the potential for burials. Should burials or other cultural finds be identified during ground disturbance, the construction contractor would immediately cease all work in the area, and the appropriate agencies would be notified pursuant to applicable laws, including NHPA and HRS Section 6E (EC CUL-3). Implementing procedures regarding burials as stipulated in the Programmatic Agreement and following legislative protocols for inadvertent discovery of remains would reduce impacts to a less than significant level.

Alternative 1 also include the implementation of mitigation measures to minimize induced flooding. Potential nonstructural measures that are under consideration include dry/wet floodproofing, elevation, and acquisition. These proposed measures are similar to what is included in the Nonstructural Alternative, therefore, refer to Alternative 6 for the impact analysis of these potential mitigation measures. The only nonstructural measure under consideration as a potential mitigation measure is a pump station(s), although the cost of construction would make this mitigation measures highly unlikely to occur. The precise location of a pump station(s) is unknown at this time; however, it would likely be located along Makiki Stream somewhere between Fern Street and the confluence of Makiki Stream with the Ala Wai Canal. If found to be necessary, the location of the pump station along Makiki Stream would attempt to avoid impacting any historic properties. However, the construction of the pump station would require excavation into the ground adjacent to Makiki Stream for the wet well. Therefore, there is a high possibility that ancestral bones may be present within the pump station area and that land-disturbing activities during construction may uncover presently undetected burials or other cultural materials. The Programmatic Agreement stipulates measures that USACE will undertake to address the potential for burials. Should burials or other cultural finds be identified during ground disturbance for the pump station(s), the construction contractor would immediately cease all work in the area, and the appropriate agencies would be notified pursuant to applicable laws, including NHPA and HRS Section 6E (EC CUL-3). Implementing procedures regarding burials as stipulated in the Programmatic Agreement and following legislative protocols for inadvertent discovery of remains would reduce potentially significant adverse impacts to less than significant. The operation and maintenance of the pump station(s) is expected to have no impact on cultural resources.

Overall, Alternative 1 would have a potential short-term significant adverse impact on cultural resources; however, this impact would be reduced to less than significant with the implementation of environmental commitments EC CUL-1 through EC CUL-4. Long-term, the operation and maintenance of the project is expected to have a temporary less than significant adverse impact to access to cultural practices.

Table 42: Historic Properties Potentially Affected by the Ala Wai Canal Flood Risk Management Project.

Measure Location/Description	Site ID	Criteria	Effects Determination	Treatment Recommendation
1) Makiki: Makiki District Park Detention Basin				
Makiki District Park	No SIHP Assigned	None	Not historic	Monitoring during construction
2) Makiki: Kanaha Floodwall				
Makiki Stream	No SIHP Assigned	e	No Effect	Micrositing to avoid significant resources
3) Manoa: Manoa Valley Park Detention Basin				
Manoa Valley District Park	No SIHP Assigned	None	Not historic	Monitoring during construction
4) Manoa: Woodlawn Drive Floodwall				
None				
5) Manoa: Koali Road Floodwall				
None				
6) Palolo: Koali Road Floodwall				
None				
7) Manoa-Palolo: Kaimuki High School				
Manoa-Palolo Canal	Inventory No. 36	A,C	Adverse effect	Historic documentation
8) Manoa-Palolo: Ala Wai Golf Course				
Ala Wai Golf Course	No SIHP Assigned	None	Not historic	Monitoring during construction
Manoa-Palolo Canal	Inventory No. 36	A,C	Adverse effect	Historic documentation
9) Ala Wai: Ala Wai Canal Floodwalls				
Kalakaua Avenue Bridge	Inventory No. 02	A,C	Adverse effect	Match design with existing walls
McCully Street Bridge	Inventory No. 03	A,C	Adverse effect	Match design with existing walls
Kapahulu (Ala Wai Golf Course) Drainage	No SIHP Assigned	None	Not historic	Not historic
Ala Wai Canal	50-80-14-9757	A	Adverse effect	Mitigation plan/ historic documentation/ consulting party design & input

Measure Location/Description	Site ID	Criteria	Effects Determination	Treatment Recommendation
Ala Wai Park Clubhouse (City and County of Honolulu Art Deco Parks and Playgrounds)	50-80-14-1388/ No.90	C	Adverse effect	Historic documentation/ consulting party design input

Alternative 2B

Less than Significant Impact with Environmental Commitments Incorporated: In general, the type of project features included in Alternative 2B would have similar construction, operation, maintenance, and mitigation requirements as Alternative 1, such that the nature and degree of potential impacts to cultural and archaeological resources are generally expected to be similar. Therefore, refer to the analysis under Alternative 1 for Alternative 2B project impacts.

Alternative 2B differs from Alternative 1 in that it includes a floodwall around the Ala Wai Canal. In addition to implementing EC CUL-1 and EC CUL-2, EC CUL-4 would be implemented for the Ala Wai Canal floodwall specifically. EC CUL-4 includes an elevated walkway adjacent to the Ala Wai Canal floodwall to minimize visual impacts. In addition, as per the PA, design input to further minimize visual impacts to the greatest extent possible will be solicited from SHPO and interested consulting parties, and incorporated, as feasible, into the final design and construction of the floodwalls. The appropriate level of historic documentation of the Ala Wai Canal will also be developed with SHPO and other consulting parties. The elevated walkway would be approximately three feet above ground whereas the floodwall around the Ala Wai Canal would be approximately six feet above ground. This would allow the community, especially pedestrians, to still be able to see the water within the canal when they are walking on the elevated walkway. With the construction and operation of the Ala Wai Canal floodwall, there are four canoe launches that have the potential to be impacted (i.e., Manoa-Palolo Canoe launch, Canoe Club launch, Waikiki Surf Club and Boat Launch, and Kamehameha Canoe Club). Currently, the feasibility level design includes structures similar to road closure structures at each of the four canoe launches to minimize impacts to these properties and associated cultural practices. Overall, Alternative 2B would have a potential short-term significant adverse impact on cultural resources; however, this impact would be reduced to less than significant with the implementation of environmental commitments EC CUL-1 through EC CUL-4. Long-term, the operation and maintenance of the project is expected to have a temporary less than significant adverse impact to access to cultural practices.

Alternative 5.3

Less than Significant Impact with Environmental Commitments Incorporated: In general, the type of project features included in Alternative 5.3 would have similar construction, operation, maintenance, and mitigation requirements as Alternative 1 and Alternative 2B, such that the nature and degree of potential impacts to cultural and archaeological resources are generally expected to be similar. Therefore, refer to the analysis under Alternative 1 and Alternative 2B for Alternative 5.3 project impacts. Overall, Alternative 5.3 would have a potential short-term significant adverse impact on cultural resources; however, this impact would be reduced to less than significant with the implementation of environmental commitments EC CUL-1 through EC CUL-4. Long-term, the operation and maintenance of the project is expected to have a temporary less than significant adverse impact to access to cultural practices.

Alternative 6

Less than Significant Impact with Environmental Commitments Incorporated: No infrastructure facilities in Honolulu have been identified as NRHP-eligible, so their modifications would not cause adverse effects to historic properties. However, where measures may cause ground disturbance, archaeological survey would be needed.

The potential elevation of any historical structures would consist of elevating the foundation of the structure on a new foundation so that the lowest finished flood is approximately above 12 feet NAVD88. All utilities and mechanical equipment, such as air conditioners and hot water heaters would also be raised to this elevation. Floodproofing of historic structures would consist

of sealing all areas of a structure up to a maximum of approximately three feet above ground level to reduce damage caused by coastal storm surge inundation by making walls, doors, windows, and other openings resistant to penetration by water. Walls would potentially be coated with sealants, waterproofing compounds, or plastic sheeting. Back-flow from water and sewer lines would be prevented by installing mechanisms such as drain plugs, standpipes, grinder pumps, and back-up valves. Openings, such as doors, windows, sewer lines, and vents, may also potentially be closed temporarily with sandbags or removable closures, or permanently sealed.

In residential areas, nonstructural measures would potentially cause moderate impacts to any NRHP eligible buildings. Elevating any NRHP eligible structure would be an adverse effect, but some designs are less so than others. Elevations may cause adverse visual effects to a historic district. Floodproofing may be adverse, or non-adverse. Dry floodproofing designs which require windows and doors to be sealed would cause adverse effects. There would also be beneficial effects to historic structures as the elevation and floodproofing measures would prevent flood damages to the structure. This alternative would be expected to have permanent, moderate adverse to beneficial effects.

Environmental Commitments

The following environmental commitments would be implemented to reduce potential impacts to cultural resources during construction of the project.

EC CUL-1: Historic buildings, bridges, and walls affected by construction would undergo appropriate historic documentation, and design input would be solicited from SHPO and interested consulting parties and incorporated into the final design where feasible. Where possible, impacts to archaeological resources would be avoided. Where avoidance is not possible, data recovery would be performed. Where practicable, construction measures would be microsited either up or downstream to minimize the impacts to features of Native Hawaiian cultural significance (Traditional Cultural Property [TCPs]) that could be disturbed by project actions.

EC CUL-2: Design input to minimize visual impacts to the greatest extent possible will be solicited from SHPO and interested consulting parties, and incorporated, as feasible, into the final design and construction of floodwalls.

EC CUL-3: If previously unknown cultural resources are discovered, work in the immediate area would cease until the requirements in 36 CFR 800.13 are complied with. The on-site supervisor shall contact the USACE's Project Manager and District Archaeologist, and an approved archaeological consultant immediately. The on-site supervisor shall additionally divert all Proposed Action-related activities to other areas until the discovery has been evaluated by the approved archaeological consultant. The USACE will determine if further mitigation measures are warranted in consultation with the SHPO and consulting parties.

EC CUL-4: Design of the Ala Wai Canal floodwalls includes an elevated walkway where feasible. In addition, as per the PA, design input to further minimize visual impacts to the greatest extent possible will be solicited from SHPO and interested consulting parties, and incorporated, as feasible, into the final design and construction of the floodwalls. The appropriate level of historic

documentation of the Ala Wai Canal will also be developed with SHPO and other consulting parties.

Best Management Practices

No BMPS associated with impacts to cultural resources apply.

3.5.2 Land Use and Planning

Regulatory Setting

Relevant federal and state laws/regulations include:

- Coastal Zone Management Act
- Farmland Protection Policy Act
- EO 11988 (Floodplain Management)
- HAR, Title 13, Chapter 5 – *Conservation District Rules*
- HRS, Chapter 25 – *State Land Use Law*
- HRS, Chapter 115 – *Public Access to Coastal and Inland Recreational Areas*
- HRS, Chapter 183C – *Conservation District*

Existing Conditions

A variety of different land uses are present in the watershed, both in urban and undeveloped areas. Land uses are primarily controlled by State Land Use designations, and further by County zoning designations. A summary of the existing lands uses, as well as the land use districts and zoning for each of the measures in the alternatives under consideration are listed in Table 43. For additional detail refer to the 2017 Ala Wai Canal Flood Risk Management Project, Oahu, Hawaii Integrated Feasibility Study and Environmental Impact Statement (USACE, 2017).

Table 43: Land Use Designations of Measure Sites

Measure	Existing Land Use	State Land Use	County Zoning	Special Management Areas (SMA) and Other Special Districts
Kanaha Floodwall	Adjacent to residential and commercial properties.	Urban	P-2	Not in SMA
Makiki District Park Detention Basin	Makiki District Park; adjacent to residential and commercial properties and St. Clements School	Urban	A-2	Not in SMA
Manoa Valley District Park Detention Basin	Manoa District Park; adjacent to residential properties and an elementary school	Urban	P-2	Not in SMA
Woodlawn Drive Floodwall	Adjacent to residential properties	Urban	R-7.5	Not in SMA
Koali Road Floodwall	Adjacent to residential properties	Urban	R-5	Not in SMA
Kaimuki High School Floodwall	Kaimuki High School; adjacent to Ala Wai Golf Course, commercial and residential properties	Urban	A-2	Not in SMA

Measure	Existing Land Use	State Land Use	County Zoning	Special Management Areas (SMA) and Other Special Districts
Ala Wai Golf Course Detention Basin	City & County Golf Course	Urban	P-2	Not in SMA
Ala Wai Canal Floodwalls	Open space associated with Ala Wai Canal, Ala Wai Promenade, and Ala Wai Community Park; adjacent to commercial and residential properties and an elementary school within Waikiki District	Urban	Public Precinct	Not in SMA; in Waikiki Special District

Significance Criteria

Effects on land use would be considered significant if the proposed project would result in any of the following:

- Preclude use of an area for its intended purposes or displace an existing land use.
- Substantially conflict with the objectives of any applicable land use regulation, plan, or policy.
- Directly or indirectly induce substantial population growth or development in a floodplain.
- Physically divide and/or affect the social connectedness of an established community.
- Displace substantial numbers of existing people or housing.

Environmental Consequences

No Action Alternative

No Impact: Under the No Action Alternative, no flood-risk management measures would be implemented and as such, significant portions of the watershed would continue to be at risk of flooding, thus threatening existing land uses (particularly in the urbanized watershed). Over the 50-year period of analysis for the future without-project condition, the boundaries and intended uses of the various land use designations are expected to be maintained. No portion of the Conservation District is expected to be rezoned to allow development. Within the Urban District, nearly all available land is already developed, leaving very little area for future development. As is already occurring, future development activities are expected to primarily consist of redevelopment of existing lots (CCH, 2023a).

Alternative 1

Less than Significant Impact with Environmental Commitments Incorporated: Construction of Alternative 1 would result in short-term temporary impacts to land use. Alternative 1 includes the construction of detention basins within Makiki District Park, Manoa Valley District Park, Kaimuki High School, and Ala Wai Golf Course. Construction of the Makiki District Park and Manoa Valley District Park detention basins requires excavating down 6-8 feet, constructing floodwalls around the basin, and constructing inlet and outlet structures for the basin. All these activities would prevent use of the park area while construction is occurring. Once construction is complete, activities could resume within the park areas. Regarding Kaimuki High School and the Ala Wai Golf Course, construction of the detention basins at these

locations would only involve floodwalls, and construction of an inlet and outlet structures for the golf course only. Use of portions of the athletic fields at the high school may be restricted during construction, although most activities would still be able to occur. Similarly, play at the golf course would likely be able to continue during construction, although use of some areas might be restricted. Once construction is complete, use of the athletic fields and play at the golf course would continue and areas that may have been restricted during construction would no longer be restricted.

The construction of floodwalls alone (i.e., Kanaha floodwall, Woodlawn Drive floodwall, Koali Road floodwall) would also result in short-term temporary impacts to land use while construction is occurring. The floodwalls are primarily located along urban corridors or near resident property lines. Measures would be implemented to include phasing of construction to minimize the extent of disturbance at any given time, and restoration of temporarily disturbed areas to pre-project conditions. In addition, for work on privately owned land, easements would be obtained, and would include fair compensation for loss of use by landowners during construction. Long-term, there would be temporary impacts to land use at Makiki District Park, Manoa Valley District Park, Kaimuki High School, and Ala Wai Golf Course during a storm event as the detention basins would begin to retain water beginning at the 5% AEP flood event. As the detention basins begin to collect stormwater, use of these areas would not be possible. In addition, use of these areas would not be able to resume until the detention basins are drained of water and any repairs to the areas from storm damage are complete (i.e., debris removal, replanting vegetation, etc.). It is important to note, however, that storms of the 20-year event and above currently flood these locations under the No Action Alternative preventing their use even without implementation of a project. In addition, the detention basins at the park districts are expected to retain stormwater for approximately 1 day before slowly draining and the Ala Wai Golf Course detention basin is expected to retain stormwater for approximately 2 days before slowly draining. Therefore, the time to resumption of activities at these locations would not be substantially increased under the with-project condition. Overall, due to the short-term nature of the construction activities and the short-term nature of storm events, the project is not expected to substantially preclude the use of an area for its intended purposes or displace an existing land use. Therefore, the impact to an existing land use would be less than significant.

As noted under the No Action Alternative for Land Use, nearly all available land within the Urban District of the Ala Wai watershed is already developed, leaving very little area for future development. Therefore, construction of the proposed project would protect existing residential and commercial properties from flood damages and would not promote development in the floodplain. Overall, the project would have no short-term or long-term impacts to development in the floodplain.

Alternative 1 also includes the implementation of potential mitigation measures to minimize induced flooding. Potential nonstructural mitigation measures that are under consideration include dry/wet floodproofing, elevation, and acquisition. These types of measures are part of the Nonstructural Alternative, therefore, refer to the impact analysis under Alternative 6. The only structural mitigation measure under consideration is a pump station(s), however, the cost of the pump station(s) makes it highly unlikely that it will be constructed. Regardless, the potential impacts of a pump station(s) follow. The exact location of the pump station(s) is unknown at the time; however, the pump station would likely be located along Makiki Stream between Fern Street and the confluence of Makiki Stream with the Ala Wai Canal. This general area is zoned A-2 (Medium-density Apartment District), BMX-3 (Community Business Mixed Use District), and AMX-2 (Medium-density Apartment Mixed Use District). Therefore, construction of the pump station(s) would not have any adverse impacts to the existing land uses or zoning within and

around the location of the pump station. There could be temporary minor adverse impacts surrounding the availability of parking while construction of the pump station(s) is occurring; however, the precise location of the pump station(s) is unknown at this time. Therefore, the construction, operation, and maintenance of the pump station(s) is not expected to alter the current land use within the general area or affect surrounding land uses, so no potential impacts are expected.

Overall, in terms of land use, the project would not substantially conflict with the objectives of any applicable land use regulation, plan, or policy; convert prime farmland, unique farmland, or farmland of statewide importance to non-agricultural uses; result in the loss of forest land or conversion of forest land to non-forest use; or directly or indirectly induce a substantial degree of development in a floodplain. In summary, the proposed project would have short-term and long-term minor adverse impacts on land use due to construction, maintenance, and operation activities precluding the use of an area for its intended purposes for a temporary time.

Alternative 2B

Less than Significant Impact with Environmental Commitments Incorporated: In general, the type of project features included in Alternative 2B would have similar construction, operation, maintenance, and mitigation requirements as Alternative 1, such that the nature and degree of potential impacts to land use are generally expected to be similar. Therefore, refer to the analysis under Alternative 1 for Alternative 2B project impacts. Overall, Alternative 2B would have short-term and long-term minor adverse impacts on land use.

Alternative 5.3

Less than Significant Impact with Environmental Commitments Incorporated: In general, the type of project features included in Alternative 5.3 would have similar construction, operation, maintenance, and mitigation requirements as Alternative 1 and Alternative 2B, such that the nature and degree of potential impacts to land use are generally expected to be similar. Therefore, refer to the analysis under Alternative 1 and Alternative 2B for Alternative 5.3 project impacts. Overall, Alternative 2B would have short-term and long-term minor adverse impacts on land use.

Alternative 6

Less than Significant Impact with Environmental Commitments Incorporated: Approximately 43 residences would be eligible for elevation or raising of their homes. It is currently unknown how many of the homes are structurally sound enough for an elevation. Elevation of structures would apply only to residences, and floodproofing would be done for critical infrastructure and some government facilities. The nonstructural measures are voluntary; therefore, any owner may opt out, but tenants would be subject and affected by the landlord's decision. Floodproofing treatments would be done for approximately 1501 commercial and governmental facilities. In these locations, the land use would not change. However, there would be a direct, long-term significant beneficial effect on land use because those residences and facilities would be more resilient to flooding. Alternative 6 should result in fewer flood damages to structures.

Alternative 6 would require the temporary relocation of residents during elevation construction, which would be a significant, short-term direct adverse effect due to the relative scarcity of housing. Construction would have to be phased such that there is adequate temporary housing available for each phase, to reduce the impact on residents and land use (EC LUP-1). Temporary indirect and direct adverse effects would result from construction noise and presence and use of heavy equipment in residential and commercial land use areas. It is

anticipated that, if possible, the nonstructural measures for whole blocks or streets of residences could be closed off and conducted simultaneously, so that construction windows within neighborhoods can be minimized (EC LUP-2).

Environmental Commitments

The following environmental commitments would be implemented to reduce potential impacts to land use and planning during construction of the project.

EC LUP-1: Phase construction to ensure there is adequate temporary housing available due to scarcity of housing in the area.

EC LUP-2: Simultaneously implement nonstructural measures for whole blocks or streets of residences so that construction windows within neighborhoods can be minimized.

Best Management Practices

No BMPS associated with impacts to land use and planning apply.

3.5.3 Hazardous, Toxic, and Radioactive Waste

Regulatory Setting

Relevant federal and state laws/regulations include:

- Resources Conservation and Recovery Act (RCRA)
- Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA)
- Hawaii Administrative Rules, Chapter 11-260.1 – Hazardous Waste Management

Existing Conditions

In the 2017 Ala Wai Canal Flood Risk Management EIS, an assessment identified a variety of hazardous, toxic, and radioactive waste (HTRW) sites within the Manoa watershed. Additional information regarding the assessment results is provided in the Final Reconnaissance Phase Hazardous, Toxic, and Radioactive Waste Assessment for the Ala Wai Watershed Project (Myounghee Noh and Associates, 2009). The HTRW investigation was updated in 2023 to account for the changes in alternatives and in conditions. The updated assessment can be found in Appendix J.

Significance Criteria

The proposed project would result in potential significant impacts to HTRW if it would:

- Create a significant hazard to the public or the environment through the routine transport, use, or disposal of hazardous materials.
- Create a significant hazard to the public or the environment through reasonably foreseeable upset and accident conditions involving the release of hazardous materials into the environment.
- Emit hazardous emissions or handle hazardous or acutely hazardous materials, substances, or waste within one-quarter mile of an existing or proposed school.
- Be located on a site which is included on a list of hazardous materials sites and, as a result, would create a significant hazard to the public or the environment.

Environmental Consequences

No Action Alternative

No Impact: Under this alternative, no flood risk management features would be implemented by USACE. There would not be any disturbance to existing known or suspected waste sites or materials.

Alternative 1

Less than Significant Impact: Under this alternative, several detention basins would be constructed on recreational areas, and floodwalls would be constructed along portions of the waterways. A database investigation did not uncover any unresolved hazardous waste or remediation sites within the footprint of the proposed work thus it is not expected that any release of hazardous waste or transport of such materials would occur. Because the alignment of features may change during design phase and due to the dynamic nature of urban areas, it is recommended that the database sites near the proposed measures be reviewed during design to determine whether there are any impacts.

Construction of the detention basins, including the inlet and outlet structures, will involve excavation of soils and/or sediment. The quality of this material is unknown, however due to human impacts, the soil and sediment may contain pesticides, metals, PCBs and other organic compounds. It is recommended that future testing be conducted on materials that will be excavated, to determine the suitability of the soil for re-use or to determine proper disposal.

Alternative 1 also includes the potential implementation of mitigation measures to minimize induced flooding within the watershed. Nonstructural mitigation measures currently under consideration include dry/wet floodproofing, elevation, and acquisition. These potential nonstructural mitigation measures are similar to the nonstructural measures included under the Nonstructural Alternative. Therefore, refer to Alternative 6 below for an analysis of potential impacts to HTRW. The only structural mitigation measure under consideration is a pump station(s), although the cost of construction makes it highly unlikely that this potential mitigation measures will be implemented. Regardless, a discussion of the potential impacts that may result due to construction and operation of a pump station(s) is included below. Construction of the pump station(s), including the wet well, will involve excavation of soils. The quality of this material is unknown, however, due to human impacts, the soil may contain pesticides, metals, PCBs, and other organic compounds. It is recommended that future testing be conducted on materials that will be excavated to determine the suitability of the soil for re-use or to determine proper disposal.

During construction of the project features including potential mitigation measures, it is expected that the construction contractor would have a limited amount of potentially hazardous materials on site, including petroleum, oils, lubricants, degreasing compounds and similar materials needed for equipment operation and maintenance. A spill prevention plan would be required. Spill prevention methods, such as using drip pans for refueling operations and using containment pallets for storing barrels of liquid materials, would prevent the release of hazardous materials to the environment.

Once constructed, the detention basins and other disturbed soil areas (e.g., floodwalls, mitigation measures, etc.) will be either stabilized with vegetation (grass) or riprap (stone) to prevent erosion. All construction debris or waste materials would be properly disposed of off-site. The completed features will not create any potential for the release of hazardous materials or wastes.

Alternative 2B

Less than Significant Impact: Alternative 2B contains similar features to Alternative 1. There are no known hazardous waste or remediation sites within the proposed footprint of the measures, however it is recommended that the database results be updated and reviewed at the time of construction. All other issues, including excess soil handling, the use of potentially hazardous materials during construction, and the final state of the project features, would be similar to Alternative 1.

Alternative 5.3

Less than Significant Impact: Alternative 5.3 contains similar features to Alternative 1 and Alternative 2B. There are no known hazardous waste or remediation sites within the proposed footprint of the measures, however it is recommended that the database results be updated and reviewed at the time of construction. All other issues, including excess soil handling, the use of potentially hazardous materials during construction, and the final state of the project features, would be similar to Alternative 1 and Alternative 2B.

Alternative 6

Less than Significant Impact: Alternative 6 involves disturbance to existing structures of varying ages; therefore, the potential exists for some structures to contain lead-based paint (LBP), asbestos containing materials (ACM), or polychlorinated biphenols (PCBs). As a result, a Phase 1 Environmental Site Assessment should be conducted for any affected structure constructed prior to 1978. If any such contaminants are found, the construction contract must include procedures for the lawful demolition, removal, and disposal of such wastes. With this stipulation, there would be negligible adverse long-term and minor adverse short-term impacts on HTRW.

Environmental Commitments

No environmental commitments associated with impacts to HTRW apply.

Best Management Practices

Implementation of the following BMPs would ensure no release of hazardous materials, wastes or substances to the environment, and no impact to humans or the environment from hazardous materials, wastes or substances.

- Review of database returns and the conditions of adjacent properties during design phase, to ensure that any issues have been identified and addressed properly.
- Perform a Phase II investigation on any soil or sediment that will be excavated during construction, to determine appropriate disposition of the materials and any special handling requirements.
- Construction contractors shall develop a spill prevention plan and related Standard Operating Procedures (SOPs) to prevent the accidental release of fuels, oils, solvents or other potentially hazardous materials that will be stored or used on the project worksite.
- Construction contractors shall maintain spill response products and supplies on site during the project construction, to control any accidental releases to water or soil.
- All soils hauled off site shall have covered loads to prevent dirt from blowing into residential neighborhoods.
- Trucks shall use tire brushes or other methods to prevent tracking soils onto local roads.

3.5.4 Recreation

Regulatory Setting

Relevant federal and state laws/regulations include:

- Hawaii Revised Statutes, Chapter 115 – Public Access to Coastal and Inland Recreational Areas
- HRS Chapter 183 (Forestry and Wildlife; Recreation Areas; Fire Protection)
- HRS Chapter 198D (Hawaii Statewide Trail and Access System)
- ROH Chapter 10 (Rules, Regulations, Charges, and Fees for Public Parks and Recreation Facilities)

Existing Conditions

A wide range of recreational resources are available within the Ala Wai watershed, including federal, state, and county parks; hiking trails; a golf course; boating facilities; and the Ala Wai Canal. A brief description of recreational resources within the study area follows.

Park Facilities

Over 400 acres of City and County of Honolulu parks are located within the Ala Wai watershed, including two regional parks (i.e., Kapiolani Regional Park and Ala Moana Regional Park), two beach parks, four district parks, eight community parks, five neighborhood parks, ten mini-parks, eight urban parks, and several miscellaneous facilities. State Park facilities within the study area include Makiki Tantalus Recreation Area, Puu Ualaka State Park, and Waahila Ridge State Recreation Area; the Honolulu Forest Reserve also offers recreational opportunities. The only federal park facility within the Ala Wai watershed is the Fort DeRussy Armed Forces Recreation Center (Fort DeRussy Park), located in Waikiki.

Trails

Administered by DLNR DOFAW, Na Ala Hele is the State of Hawaii's Trail and Access Program. Developed in response to concerns over decreasing public access to trails and development threats to historic trails, Na Ala Hele is responsible for inventorying, constructing, maintaining, and regulating activities within their network of trails. A total of 15 Na Ala Hele trails are located within the Ala Wai watershed (DLNR, 2009c). Average use varies between trails, but is highest for the Manoa Falls Trail, which is a popular tourist destination.

Ala Wai Golf Course

The Ala Wai Golf Course is one of six municipal golf courses managed by the City and County of Honolulu, Department of Enterprise Services, Golf Course Division. It is located along the Ala Wai Canal on land owned by the State and is approximately 146 acres in size. It is the only public golf course located in the Honolulu area. The 18-hole course has been distinguished as the busiest golf course in the world, with about 500 rounds played per day (or 180,000 rounds annually).

Boating Facilities

Several boating facilities are located within the Ala Wai watershed, including the Ala Wai Small Boat Harbor and Kewalo Basin, as well as moorings off Waikiki Beach. Located between Waikiki and Ala Moana beaches, the Ala Wai Small Boat Harbor is the only recreational harbor in the Ala Wai watershed. Located on the west side of Ala Moana beach, approximately one mile west of the Ala Wai Small Boat Harbor, Kewalo Beach is a mixed-use harbor that provides berthing for commercial fishing and recreational vessels. In addition to these two facilities,

DOBOR provides temporary anchorage immediately offshore of Waikiki, from Fort DeRussy to Diamond Head (Kapua Channel moorings) (DLNR, 2009a).

Canoe Launches

There are approximately four designated canoe launches within the study area. Three are located along the Ala Wai Canal and one is located along the Manoa-Palolo Canal. The Kamehameha Canoe Club Hilo is located along the Ala Wai Canal between McCully Street and the Ala Wai Community Park. The club was originally founded in 1947 and promotes the art and sport of outrigger canoe racing. There are three separate canoe launches associated with the Kamehameha Canoe Club Hilo. The Waikiki Surf Club and Boat Launch is located along the Ala Wai Canal at the termination of University Avenue, between the Ala Wai Community Park and the Ala Wai Elementary School. The Waikiki Surf Club is one of the older outrigger canoe paddling clubs on Oahu having been founded in 1948.There are four separate cone launches associated with the Waikiki Surf Club. The Lokahi Canoe Club is located along the Ala Wai Canal between the Waikiki-Kapahulu Public Library and the Ala Wai Golf Course Club House. The Lokahi Canoe Club was formed in 1980 with one paved canoe launch. Lastly, the Iolani School has a canoe launch along the Manoa-Palolo Canal near the intersection of Hihiwai Street and the Iolani School driveway.

Ala Wai Canal

The Ala Wai Canal offers a variety of recreational opportunities, including outrigger canoe paddling, kayaking, and fishing; it supports the single largest concentration of canoe clubs in the State (Belt Collins, 1998). In addition, the promenade and other pathways along the Ala Wai are heavily used for walking, running, and biking. Overall, the Ala Wai Canal System (including the contributing streams) has been identified as a regionally outstanding recreational resource, as defined based on the diversity of high-quality experiences, unique characteristics, or unique combination of recreational attributes (Hawaii Cooperative Park Service Unit, 1990). The Ala Wai Canal is the most heavily used inland waterway in the state for recreational activities and is in almost constant use nearly every day of the year (Belt Collins, 1998). Access into the Ala Wai Canal is primarily via the following seven sites: Waikiki-Kapahulu Library, Manoa-Palolo Drainage Canal, Ala Wai Neighborhood Park, Ala Wai Community Park, Magic Island, Ala Wai Small Boat Harbor, and the Ala Wai Channel. Despite significant human health issues associated with poor water quality, fishing is another common recreational activity in the Ala Wai Canal. Fishing activities include pole fishing, throw netting, fay netting, and crabbing (Belt Collins, 1998). The Ala Wai Canal is regulated as a Fisheries Management Area (FMA), under which fishing or taking aquatic life is restricted to the conditions established by DLNR DAR (DLNR, 2009b).

Waikiki Beach

In addition to the designated beach parks managed by the City and County of Honolulu, Waikiki Beach itself offers some of the most popular recreational opportunities in the Ala Wai watershed. Waikiki Beach is one of the most popular beaches in the world with over 4 million visitors each year (CCH, 2023b). Recreational opportunities at Waikiki Beach include sailing, outrigger canoe paddling, kayaking, snorkeling, scuba diving, body boarding, surfing, swimming, fishing, walking, and sunbathing (DOT, 1981).

Significance Criteria

Effects to recreation would be considered significant if the proposed project would result in any of the following:

- Permanently restrict access to designated recreational areas.

- Substantially reduce availability of and access to designated recreational or open space areas.
- Increase the use of existing recreational areas such that substantial physical deterioration would occur or be accelerated.
- Include recreational facilities or require the construction or expansion of recreational facilities which might have an adverse physical effect on the environment.

Environmental Consequences

No Action Alternative

No Impact: Over the period of analysis for the project, the type and extent of recreational opportunities are expected to be consistent with the existing condition. Given the extent of development within the watershed, little to no open space is available to support new recreational facilities.

Under the No Action Alternative, recreational facilities and activities within the watershed would not be affected by construction of flood-risk management measures. However, in the absence of these flood risk management measures, significant portions of the watershed would remain within the 1% AEP floodplain and would continue to be subject to flood conditions, including the Manoa Valley District Park, Kanewei Community Park, Ala Wai Golf Course, and Ala Wai Community Park. It is expected that these sites would not be available for recreational use during and immediately following flood events (to allow for post-flood clean up and recovery).

Alternative 1

Significant Impact: Construction of the measures comprising Alternative 1 would result in short-term temporary impacts to recreational. Construction of the Manoa Valley District Park detention basin would render the four baseballs fields located along the right descending bank of Manoa Stream in accessible while construction is occurring. Similarly, construction of the Makiki District Park detention basin would render the large open field adjacent to Wilder Avenue inaccessible while construction is occurring. Construction of the Ala Wai Golf Course detention basin would involve floodwalls/earthen berm around the perimeter of the Golf Course. Therefore, play at the golf course is expected to be able to continue while construction is occurring, although the use of some areas might be temporarily restricted. Construction of the Woodlawn Drive floodwall would temporarily restrict land access to Manoa Stream along the right descending bank for recreational activities such as fishing, canoe access, bird watching, etc. There are no designated parks or open space in this area, however. Construction of the Koali Road floodwall is likely to cause temporary, short-term restricted areas to the public along the portion of Kanewei Community Park that is adjacent to the right descending bank of Manoa Stream as construction of the floodwall would be occurring here. Much of the park, however, would still be accessible to the public. In addition, land access to Manoa Stream and Palolo Stream where the floodwall is being constructed would be temporarily restricted for recreational activities such as fishing, canoe access, bird watching, etc. Construction of the Kaimuki High School floodwall is likely to cause temporary, short-term restricted areas to the public along the portions of the athletic fields and track that are adjacent to where the floodwalls would be located. Lastly, construction of the Kanaha floodwall is likely to cause temporary, short-term restricted areas to the public, especially for recreational activities such as fishing, canoe access, bird watching, etc. I''s important to note that the location of the Kanaha floodwall is heavily urbanized with property lines backing up to the Makiki Stream bank, so there is already limited access under the existing condition.

Long-term, there would be significant impacts to recreational activities along the waterways and within the parks that would be directly affected by the project. Floodwalls would permanently restrict land access to the waterways where the floodwalls are located. This would restrict use of these areas by recreational users trying to fish from the bank, launching a canoe/kayak, bird watching, etc. Access to Manoa Valley District Park would not permanently restrict access to designated recreational areas, but it would reduce availability of a portion of a designated recreational area. The detention basin at Manoa Valley Park District would permanently remove the four baseball fields where the detention basin is constructed; and due to the conversion of a flat area to concave, reconstruction of the baseball fields after construction would not be possible. The area would be planted with grass and could be used as an open space area, but use of the area for athletic fields would not be possible. Also, due to the lack of availability of open space within the current footprint of the Manoa Valley District Park, the baseball fields would be a long-term permanent loss. The detention basin at Makiki District Park would not permanently restrict access to a designated recreational area long-term, nor would it substantially reduce availability of a designated recreational / open space area. Although the flat open space would be converted to a concave open space, it would still be open space. The remainder of the areas discussed above (i.e., Ala Wai Golf Course, Kaimuki High School, etc.) would not be permanently impacted by restricting access long-term or substantially reducing availability of and access to a designated recreational or open space area. The designated uses of the Ala Wai Golf Course, and Kaimuki High School would be able to continue long-term.

In addition to the long-term impacts detailed above, there would also be the long-term impact of the Makiki District Park, Manoa Valley District Park, Kaimuki High School, and Ala Wai Golf Course being purposely flooded to detain water during storm events. However, it is important to note that under the No Action Alternative all the above sites except for the Makiki District Park would flood normally during a storm event. The potential difference long-term between the No Action Alternative and Alternative 1 is the duration which the water remains within these areas. After a storm event, it's anticipated that Makiki District Park and Manoa Valley District Park detention basins would retain collected water for approximately one day. Kaimuki High School, which is not a detention basin but connects to the Ala Wai Golf Course berm, is anticipated to retain water for one day as well. The Ala Wai Golf Course detention basin is expected to retain water for two days. In addition to potentially retaining water for longer under Alternative 1, these areas would also include operation and maintenance activities that could disrupt activities at these locations periodically following a storm event. Maintenance for these sites would include activities such as removing retained sediment/debris and potentially the replanting of vegetation. The floodwall drainage structures would also need to be monitored periodically for needed repairs, which could temporarily prevent activities in the area where repairs are being made.

Regarding increased use of existing recreational areas such that substantial physical deterioration would occur or be accelerated, the only area where this might happen is other parks around Manoa Valley District Park. Since the four baseball fields would be permanently removed from the Manoa Valley District Park, other baseball fields in the vicinity of the park such as those located on the University of Hawaii at Manoa and at Punahou School could experience more use. This may increase the deterioration of these baseball fields requiring more frequent repairs, however, the level of increase in use of these fields is unknown at this time.

Alternative 1 also includes potential mitigation measures that would be implemented to minimize induced flooding within the watershed. Nonstructural mitigation measures under consideration include dry/wet floodproofing, elevation, and acquisition. In general, these types of nonstructural measures make up the Nonstructural Alternative, therefore, refer to the impacts analysis under

Alternative 6 for the potential impacts of nonstructural measures on recreation. The only potential structural measure under consideration is a pump station(s), although the cost of construction makes the implementation of this feature as a mitigation measure highly unlikely. Regardless, the following is a discussion of the potential impacts on recreation a pump station(s) might have. Although the location of the pump station(s) is unknown at this time, it would likely be located along Makiki Stream between Fern Street and the confluence of Makiki Stream with the Ala Wai Canal. This general area is highly urbanized with mostly apartments and businesses. The location of the pump station(s) would not be on an area deemed as recreation, even though the precise location of the pump station(s) is unknown. During construction, the area around the pump station(s) would be fenced off for public safety. Depending on the location of the pump station and where it would be fenced off, there could be minor temporary impacts to walking and/or biking within the vicinity of this area. This would be temporary, though, and would only last the duration of construction. Once the pump station(s) is constructed, the fencing would be removed, and the area would not incur upon recreational walkers or bikers. Similarly, operation and maintenance of the pump station(s) would have no impact on recreational walkers or bikers in the area.

Lastly, Alternative 1 does not include the construction of recreational facilities or require the construction or expansion of recreational facilities which might have an adverse physical effect on the environment.

Overall, due to project features permanently restricting access to portions of the waterway and recreational areas; reducing availability of a designated recreational area; and potentially increasing the use of existing recreational areas such that substantial physical deterioration would occur or be accelerated, Alternative 1 would have a significant impact on recreation.

Alternative 2B

Significant Impact: Alternative 2B contains similar features to Alternative 1, although it lacks the Manoa Valley Park detention basin. Even though there would be no short-term or long-term impacts at this one park; the analysis of the floodwalls under Alternative 1 and their potential short-term and long-term impacts would be similar to those detailed for Alternative 1. Therefore, refer to the analysis under Alternative 1 for most of Alternative 2B project impacts.

Alternative 2B does include a floodwall around the Ala Wai Canal which is not part of Alternative 1. Construction of the Ala Wai Canal floodwall which extends along the Manoa-Palolo Canal downstream of H1 and down both sides of the Ala Wai Canal up to Ala Moana Boulevard would cause temporary restricted areas to the public being able to access/see the canals especially for recreational activities such as fishing, canoe access, bird watching, walking the river trail, etc. The Ala Wai Community Park is also adjacent to the Ala Wai Canal where floodwalls would be located. The portion of the park adjacent to the right descending bank of the Ala Wai Canal would have temporarily restricted areas where construction of the floodwalls is occurring. Much of the park, however, would still be accessible to the public.

Long-term, there would potentially be significant impacts to recreational activities along the waterway. Floodwalls have the potential of permanently restricting land access to the waterway where the floodwalls are located which would essentially prevent fishing along the canal. Canoe access could also potentially be restricted at the canoe launches along the canal. To minimize these potential impacts, the floodwall around the Ala Wai Canal would include an approximately three-foot elevated walkway adjacent to the six-foot floodwall. The elevated walkway would restore the Ala Wai Canal trail for walkers, runners, bicyclists, and other recreational users. The elevated path would also potentially allow for fishing within the canal to still occur, although site

of a fishing line in the water could still be partially impaired. In addition to the elevated walkway, the floodwall around the Ala Wai Canal would also include road closure type structures where canoe launches are located. This would allow access to the waterway for paddlers still, although launches would not be accessible prior to, during, and for a few days after a storm event when the closure structures would need to be closed.

Overall, due to project features permanently restricting access to portions of the waterway and recreational areas and reducing availability of a designated recreational area, Alternative 2B would have a significant impact on recreation.

Alternative 5.3

Significant Impact: In general, the type of project features included in Alternative 5.3 would have similar construction, operation, maintenance, and mitigation requirements as Alternative 1 and Alternative 2B, such that the nature and degree of potential impacts to recreation are generally expected to be similar. Although likely still a significant impact, the impact of Alternative 5.3 is expected to be less than the impact of Alternatives 1 or 2B since the alternative does not include the Makiki Park detention basin, Manoa Valley District Park detention basin, or the Kanaha floodwall. Nevertheless, refer to the analysis under Alternative 1 and Alternative 2B for Alternative 5.3 project impacts.

Alternative 6

Less than Significant Impact: Alternative 6 involves construction on existing upland structures and temporary construction access. Construction staging areas would be directly co-located with the affected structures. Elevation of structures would apply only to residences and would therefore have no short-term or long-term direct or indirect effects on recreation.

No known recreational facilities would be affected directly or indirectly by this alternative. However, if they are, they will be compensated and/or relocated and would be at the very least temporarily closed during construction or relocation. For these reasons, this alternative could have a direct, negligible to minor, short-term adverse effect on recreation and a negligible to minor long-term adverse effect on recreation.

Environmental Commitments

No environmental commitments apply that would reduce the significant impacts to less than significant.

Best Management Practices

No BMPs apply that would reduce the significant impact to less than significant.

3.5.5 Aesthetics

Regulatory Setting

Relevant federal and state laws/regulations include:

- National Historic Preservation Act
- Coastal Zone Management Act
- HRS Chapter 205A (Coastal Zone Management)
- HRS Chapter 183C (Conservation District)
- Hawaii Scenic Byways Program
- General Plan for the City and County of Honolulu
- Primary Urban Center Development Plan

The visual landscape of the study area, which contributes to the aesthetics of the area, are generally comprised of natural stream corridor and forested habitat in the upper Ala Wai watershed and open spaces within the heavily developed middle to lower Ala Wai watershed. The General Plan for the City and County of Honolulu has identified specific views that should be preserved within the Ala Wai watershed, including panoramic views from the Ala Wai Canal promenade and Ala Moana Beach Park toward the Koolau Mountains, as well as *mauka-makai* view corridors along major roadways. In addition to these viewplanes, other important scenic resources that have been identified include those in the Waikiki District, including the Ala Wai Canal itself, which is listed as a historic property on the Hawaii Register of Historic Places. Two scenic byways have also been established in this area under the Hawaii Scenic Byways Program: the Diamond Head Scenic Byway and the Waikiki – Kauhale O Hookipa Scenic Byway (DOT, 2015). The Diamond Head Scenic Byway spans from Kapiolani Park to Diamond Head Crater. The Waikiki – Kauhale O Hookipa Scenic Byway includes the major thoroughfares through Waikiki, including Ala Wai Boulevard.

Significance Criteria

Effects to aesthetics would be considered significant if the proposed project would result in any of the following:

- Development that substantially conflicts with the surrounding landscape (i.e., a form, line, color, or texture that contrasts with the visual setting)
- Obstruction of established viewplane, significant view corridor, or other public views or important environmental resources and/or landscapes.
- Substantial reduction of the views or aesthetic values associated with a historic property, scenic byway, or other important landmark.

Environmental Consequences

No Action Alternative

No Impact: Under the No Action Alternative, the flood-risk management measures would not be constructed and therefore would not affect visual resources. Over the period of analysis, the natural features within the watershed (including Mamala Bay, the Koolau Mountains, and other geologic landforms) are not expected to significantly change in form, color, texture, or scale. As such, the visual characteristics of these features are expected to be consistent over time. As previously noted, the urbanized portions of the watershed may be subject to redevelopment, which could affect the overall visual landscape. However, it is assumed that the existing development guidelines and standards would continue to be implemented, thus maintaining significant views and other important visual qualities.

Alternative 1

Less than Significant Impact with Environmental Commitments Incorporated: Construction of the project would involve the use of large construction equipment, exposed soils, and staged materials, which could temporarily reduce the overall aesthetic quality at each of the measure locations. However, these activities would be temporary in nature; in addition, the construction sites would be kept free of litter and excess equipment and materials, and generally maintained in a clean and organized condition, such that impacts are expected to be less than significant.

Once constructed, the measures would introduce built elements to the natural environment, which could alter the visual landscape to some degree. Recognizing the effect that the measures could have on the visual landscape; project siting and design were conducted in a manner to best integrate each measure with the natural characteristics of the site and minimize

visual impacts to the extent possible. This effort focused on using the natural topography to minimize the overall size and obtrusiveness of the proposed structures.

In the case of the Makiki, Manoa Valley, and Ala Wai Golf Course detention basins, the implementation of these features introduces a built element to existing open space areas (i.e., Makiki District Park, Manoa Valley District Park, and Ala Wai Golf Course, respectively), and would be visible from adjacent areas including surrounding residences. However, in each case, the detention basins would be comprised of an earthen/grass berm designed to be a multi-purpose feature, which once constructed, is expected to blend and be visually commensurate with the existing parks or golf course facilities. None of the detention basins are expected to substantially diminish important environmental or landscape views from or toward the open space areas, nor are they expected to affect significant view corridors, including mauka views of the Koolau Mountains. As such, impacts to aesthetics associated with the detention basins are expected to be less than significant.

In addition to the detention basins described above, the alternative would also include floodwalls along Kanaha, Woodlawn Drive Bridge, Koali Road, and Kaimuki High School. Based on the conceptual designs, the floodwalls along all these reaches are currently expected to be approximately six feet high (on average). The above floodwalls would result in permanent landscape features, leading to the following changes in visual resources. The floodwalls, especially the wall around Kaimuki High School, would be typically dominate the view and would often only be somewhat compatible due to the alternative action area being a coastal landscape commonly holding panoramic views of water. The floodwalls, being an enclosure by design, often blocks these views and becomes a dominant feature in a now enclosed landscape. The floodwalls are characterized as only somewhat compatible because in many places they disrupt th219ompletnt harmony with the coastal landform, causing the broad and open experience currently available to be lost. For example, the floodwalls would partially obstruct views of the streams from the sides of the channels they are located on. Views from within the streams by paddlers would also be obstructed. Although the floodwalls may have a significant adverse effect on aesthetic resources, construction of the floodwalls would provide significant benefits in the form of protecting residential structures and commercial structures from the risk of inundation and resulting structural damage; the No Action Alternative would not offer such protection. To mitigate for the adverse impacts to aesthetic resources, the proposed floodwalls would have a fascia of lava rock on both sides to blend the walls into the surrounding environment as well as incorporate materials from the island.

Alternative 1 also includes potential mitigation measures for induced flooding within the watershed. Potential nonstructural mitigation measures include dry/wet floodproofing, elevation, and acquisition. The Nonstructural Alternative includes similar nonstructural measures, therefore, refer to Alternative 6 for the impact analysis of these potential mitigation measures on aesthetics. The only potential structural mitigation measure under consideration is a pump station(s), although it is highly unlikely that this mitigation measure will be implemented. Regardless, a discussion of potential impacts to aesthetics from construction, operation, and maintenance of a pump station is included below. Although the precise location of a pump station(s) is unknown at this time, it is anticipated that the pump station would be along Makiki Stream somewhere between Fern Street and the confluence of Makiki Stream with the Ala Wai Canal. Construction and grading activities for the pump station(s) would require the use of heavy equipment and storage of materials on-site. During construction, excavated areas, stockpiled soils, and other materials at the construction site and staging areas would constitute negative aesthetic elements in the visual landscape. If vegetation is present on the site where the pump station(s) would be constructed it would need to be removed in order to construct the

pump station(s). However, construction would last for a short period of time and the architecture of the pump station housing would be designed to blend in with the surrounding environment. Landscaping around the structure, if feasible, would restore the appearance of the disturbed area. This would reduce the short-term adverse effects of the pump station(s) on aesthetic resources to a less than significant level. Long-term, the operation and maintenance of the pump station is not expected to have a substantial adverse impact on aesthetic resources. Maintenance would require the presence of personnel vehicles, but maintenance activities would occur within the pump station(s) housing and would not be visible to the public.

Overall, Alternative 1 is expected to conflict with the surrounding landscape visually and obstruct established local viewplanes. Therefore, Alternative 1 would have a significant adverse effect on aesthetic resources, but that effect would be reduced to less than significant with the implementation of environmental commitments (EC CUL-4).

Alternative 2B

Less than Significant Impact with Environmental Commitments Incorporated:
Construction of the project would involve the use of large construction equipment, exposed soils, and staged materials, which could temporarily reduce the overall aesthetic quality at each of the measure locations. However, these activities would be temporary in nature; in addition, the construction sites would be kept free of litter and excess equipment and materials, and generally maintained in a clean and organized condition, such that impacts are expected to be less than significant.

Once constructed, the measures would introduce built elements to the natural environment, which could alter the visual landscape to some degree. Recognizing the effect that the measures could have on the visual landscape; project siting and design were conducted in a manner so as to best integrate each measure with the natural characteristics or the site and minimize visual impacts to the extent possible. This effort focused on using the natural topography to minimize the overall size and obtrusiveness of the proposed structures.
In the case of the Makiki detention basin, refer to the analysis under Alternative 1.

In addition to the Makiki detention basin, the project would also include floodwalls along Kanaha, Woodlawn Drive Bridge, Koali Road, Kaimuki High School, Ala Wai Golf Course, and a majority of the Ala Wai Canal. Based on the conceptual designs, the floodwalls along all of these areas are currently expected to be approximately six feet high (on average). The above floodwalls would result in permanent landscape features, leading to the following changes in visual resources. The floodwalls would be typically dominant and often only somewhat compatible due to the alternative action area being a coastal landscape commonly holding panoramic views of water. The floodwalls, being an enclosure by design, often block these views and becomes a dominant feature in a now enclosed landscape. The floodwalls are characterized as only somewhat compatible because in many places they disrupt the current harmony with the coastal landform, cause the broad experience currently available to be lost. For example, the floodwalls would partially obstruct views of the streams from the sides of the channels they are located on. Views from within the streams by paddlers would also be obstructed, especially along the Ala Wai Canal. The broad expanse views are not only an important resource for the Waikiki District in general, but they are also significant in terms of the Ala Wai Canal as a historic property on the Hawaii Register of Historic Places, as well as the Kauhale O Hookipa Scenic Byway (which includes Ala Wai Boulevard). Although the floodwalls may have a significant adverse effect on aesthetic resources, construction of the floodwalls would provide significant benefits in the form of protecting residential structures and commercial structures from the risk of inundation and resulting structural damage; the No Action Alternative

would not offer such protection. To mitigate for the adverse impacts to aesthetic resources, the proposed floodwalls would have a fascia of lava rock on both sides to blend the walls into the surrounding environment as well as incorporate materials from the island. Further refinements would be made during PED and would further evaluate opportunities to reduce the dimensions of the floodwalls, as well as incorporate additional design details that may minimize potential visual impacts. This effort would incorporate design input solicited as part of the NHPA Section 106 consultation process as described in Section 3.5.1.

Although further refinements and design input would occur during the preconstruction engineering and design (PED) phase, some design elements have already been incorporated to minimize potential impacts to contributing factors to the Ala Wai Canal historic property. The current design of all the floodwalls includes a fascia of lava rock on both sides of the wall. The intent is to blend the walls into the environment and make them more visually appealing. In addition, EC CUL-4 (refer to Section 3.5.1, environmental commitments) includes an elevated walkway where feasible as part of the design for the Ala Wai Canal floodwall only. The lava rock fascia on the floodwalls and the implementation of EC CUL-4 are expected to reduce potentially significant visual and aesthetic impacts to less than significant with environmental commitments incorporated.

Alternative 5.3

Less than Significant Impact with Environmental Commitments Incorporated: In general, the type of project features included in Alternative 5.3 would have similar construction, operation, maintenance, and mitigation requirements as Alternative 1 and Alternative 2B, such that the nature and degree of potential impacts to aesthetics are generally expected to be similar. Therefore, refer to the analysis under Alternative 1 and Alternative 2B for Alternative 5.3 project impacts. Overall, Alternative 5.3 would have a short-term adverse effect and a long-term significant adverse effect to visual and aesthetic resources. The long-term significant adverse effect would be reduced to less than significant with the implementation of the lava rock fascia on the floodwalls and EC CUL-4.

Alternative 6

Less than Significant Impact: The nonstructural measures, particularly elevation, would change the appearance of homes opting in. This could be a beneficial or adverse effect, depending on perspective. Depending on current FFE, the final elevation would be between three and 12 feet off the ground. The homes would be placed on timber supports. Lifting the homes this far off the ground would make them more visible for longer distances. In some neighborhoods, only a few homes would be treated, and those might stand out in the neighborhood due to height.

Land disturbance for this alternative would be limited to modification of existing buildings. Structures that will be elevated would remain similar in appearance, except that they would be seen from further distances. Implementation of Alternative 6 would require construction access to all structures to be treated which would be expected to occur from existing roads. Similarly, localized maintenance such as repairs would be needed over time. During those timeframes only, construction vehicles would be visible. Overall, minor to moderate short-term and long-term adverse impacts to aesthetics are expected to result from implementation of Alternative 6.

Environmental Commitments

Refer to Section 3.5.1, environmental commitments for the description of EC CUL-4.

Best Management Practices

BMPs used to minimize impacts to aesthetics during construction include:

- Work and staging areas will be kept orderly and free of trash and debris.
- Construction lighting fixtures will be shielded by providing side flaps on lights. Onsite construction lighting will be arranged so that direct rays will not shine or produce glares to nearby residences.

3.5.6 Public Health and Safety

Regulatory Setting

Relevant federal and/or state laws/regulations include:

- HRS, Chapter 26 and Chapter 126 – *Civil Defense Advisory Council*
- HRS, Chapter 127A – *Emergency Management*

Existing Conditions

In the event of catastrophic flooding, potential safety threats include loss of life, injury, and post-flood health hazards. Elevated and/or high-velocity floodwaters can threaten physical health and safety (e.g., risk of drowning and injury from movement of debris and other large objects), as well as mental health (e.g., stress and anxiety). Other health and safety hazards that could occur because of flooding include potential contamination of floodwaters (e.g., including sewage, fuel oil, pesticides, and solvents); in addition, flood conditions can increase exposure to bacteria and/or mold (e.g., leptospirosis).

Flooding

As detailed under Section 3.3.4, flooding within the study area creates a public safety concern. The watershed currently has a flood warning system that includes multiple real-time rain and stream gages. These are sponsored by the City and County of Honolulu Department of Environmental Services (ENV); however, sponsorship is not expected to continue over the long-term. Although evacuation planning is an important contributor to flood-related safety, there are generally no designated evacuation routes in the study area for riverine flooding.

Flooding within the area, specifically Palolo Stream, in 2021 led to the rescue of five boys by the Honolulu Fire Department. The boys were playing in Palolo Stream after school when they were swept away by fast-moving water; none of the boys were injured in the incident.

Pollution

Pollution within the Ala Wai Canal and Ala Wai Boat Harbor has created a long-standing public safety concern. In 2006, a man died after contracting three bacterial infections from falling in the Ala Wai Boat Harbor (Cocke, 2013). Canoe paddlers who frequently use the canal complain of infections that cause sores and itchy scabs. The Canal has tested positive for now banned pesticides (e.g., dieldrin, chlordane, and DDT) and heavy metals (e.g., arsenic, mercury, lead, cadmium, copper, zinc, nickel, and chromium) linked to cancer, birth defects, and damage to the nervous system.

Significance Criteria

The proposed project would result in a potentially significant impact to public health and safety if it would:

- Increase health and safety risks to residents and visitors.
- Decrease access to or functionality of critical infrastructure, or other public facilities including schools.

- Impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan.

Environmental Consequences

No Action Alternative

No Impact: Under the No Action Alternative, the flood risk management measures would not be implemented, and public health and safety would continue to be threatened by large-scale flood events. The currently affected population of approximately 54,000 residents; 48,000 students; and approximately 79,000 visitors to the Waikiki area would remain in the 1% AEP floodplain and could potentially grow as the population increases over time.

As evidenced by past flooding events, there is some potential for life loss because of flooding in the watershed. The existing flood warning system is expected to significantly reduce the potential for life loss by providing residents and visitors with sufficient warning to evacuate; however, the long-term funding and support of the flood warning system is uncertain. Regardless, the potential flood characteristics are not projected to be of a depth and velocity that imminently threaten life safety. Rather, the more prominent health and safety threats are expected to be injuries associated with movement of debris and/or health concerns related to contaminated floodwaters.

Much of the watershed's critical infrastructure would remain within the floodplain, which elevates the risk associated with these health and safety threats. Critical infrastructure that is within the existing 1% AEP floodplain would remain subject to flooding, including four fire stations (McCully, Waikiki, Ala Moana, and Makiki), one police station (Waikiki), two medical centers (both in Waikiki) and nine emergency shelters (three in Waikiki, two in McCully/Moiliili, three in Manoa, and one in Kaimuki).

Alternative 1

Less than Significant Impact: During construction of the project, areas within the alternative footprint that may currently be available to the public would need to be cordoned off. Construction fencing would likely be placed around the perimeter of the alternative footprint that would restrict the public from accessing the construction sites. Heavy equipment will need to access the alternative footprints, including haul trucks that would periodically be coming to and from the site to provide materials/haul materials away. Signage would be posted to warn the public of entering/exiting haul vehicles while construction is occurring. Due to construction fencing and construction signage, construction of the project would not substantially increase the health and safety risks to residents and visitors to the area. Once construction is complete, the operation of the project features is passive. During a storm event, the features would detain and convey floodwaters through the system. The features would reduce the potential impact of flooding to residents and visitors within the Ala Wai Watershed. There could be concern that residents, especially children within the areas of the park detention basins, could access these sites during a flood event when the detention basins would be full of water. Signage placed around the detention basin sites would warn residents that the detention basins should not be used during storm events and would warn of the potential risk of drowning. Maintenance of the project could include heavy equipment to make repairs, clean up debris, remove sediment, etc. and smaller equipment for visual assessments of the features. Maintenance requiring larger equipment would likely only be necessary after a significant rainfall event. The use of smaller vehicles to visually assess the project features and make small repairs is expected to occur on a more regular basis. Vehicles would need to move slow in areas where the public can access the site, use flashers, and potentially put-up signage that notify the public repair work is occurring.

With the implementation of signage and safety fencing the construction, operation, and maintenance of the project is not expected to substantially increase the health and safety risks to residents and visitors to the area.

Construction of the project overall is not expected to decrease access to or functionality of critical infrastructure or other public facilities. For a discussion of the potential impacts to critical infrastructure and utilities refer to Section 3.5.7. The project does include the construction of a floodwall around the perimeter of the athletic fields for Kaimuki High School. Construction of the floodwall at Kaimuki High School has the potential to decrease access or functionality of the school's athletic fields. To minimize the potential impacts due to construction, construction could be phase to minimize disruptions during student arrival and dismissal times. Construction at the school could also be phased to occur when school is not in session (i.e., during summer break). Long-term, the operation and maintenance of the project is not expected to have a substantial impact on access of functionality of Kaimuki High School. Routine maintenance of the floodwall would likely be phased so that it occurs when school is not in session. However, emergency maintenance/repairs would need to occur as soon as possible, meaning that they could occur while school is in session. Similarly, when road closure structures are put into place, the road closure structures could interfere with access to Kaimuki High School as well as other facilities located near floodwalls. Although road closure structures could interfere with access to Kaimuki High School, access would likely not be substantially different than it is under the No Action Alternative. Under the No Action Alternative, road closures already occur during storm events due to flooding and cleanup activities post-storm. Interference to accessing Kaimuki High School would likely be like interference already experienced during storm events under the No Action Alternative. The cause of the interference would be road closure structures instead of flooding, and both alternatives would still require post-storm cleanup activities. Overall, construction and operation and maintenance of the project is not expected to substantially decrease access to or functionality of critical infrastructure, or other public facilities including schools.

The construction of the project should not substantially impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan. Project features are not located on roads nor does staging occur on any roadways where one lane of the road could potentially be temporarily closed. Haul trucks and construction personnel accessing and egressing from the site could increase traffic where it may not typically occur. This increase is not expected to substantially impair implementation or interfere with an emergency response of evaluation plan. The long-term maintenance of the project is also not expected to substantially impair implementation or physically interfere with an adopted emergency response or evacuation plan. Annual maintenance would primarily entail visually assessing the project features and making small repairs if needed. None of these activities would block a roadway for any extended period. Emergency maintenance activities such as extensive repairs, debris clean up, sediment removal, etc. could occur periodically throughout the life of the project after a large storm event. These activities are not expected to block any evacuation routes although like construction, there could be heavy equipment and repair crews accessing and egressing from a site which could increase traffic in an area where it is not typical. Regarding operation of the project, road closure features are included to bridge the gap between floodwalls where a roadway or walkway occur. These road closure features would be assembled prior to the notice of a severe storm event, during the storm event, and would be removed after the completion of the severe storm event. Road closure features put up prior to a storm event and during a storm event could physically interfere with an adopted emergency response plan or emergency evacuation plan as they would prevent movement along a roadway where they are located. The main features of concern under Alternative 1 are the road closure

structures associated with the floodwalls/earthen berms around Kaimuki High School and Ala Wai Golf Course. Under Alternative 1, the road closure structures that could impact evacuation during a tsunami warning are the road closure structure at Date Street to bridge the gap between Kaimuki High School floodwall and the Ala Wai Golf Course floodwall/earthen berm, and the road closure structure at Ala Wai Golf Course Drive. Ala Wai Golf Course Drive is not a throughway; therefore, the road closure structure here would have no impact on evacuation during a tsunami warning. The Date Street Road closure structure is a throughway and would prevent traffic from crossing the Date Street Bridge during a potential tsunami warning. There are nearby throughways such as Kapiolani Boulevard and Kapahulu Avenue which provide access to H-1 and other roadways that provide evacuees access to the tsunami safe (Figure 24). None of the other road closure structures under Alternative 1 would interfere with an adopted emergency response plan or emergency evacuation plan as they are located within the tsunami safe zone.

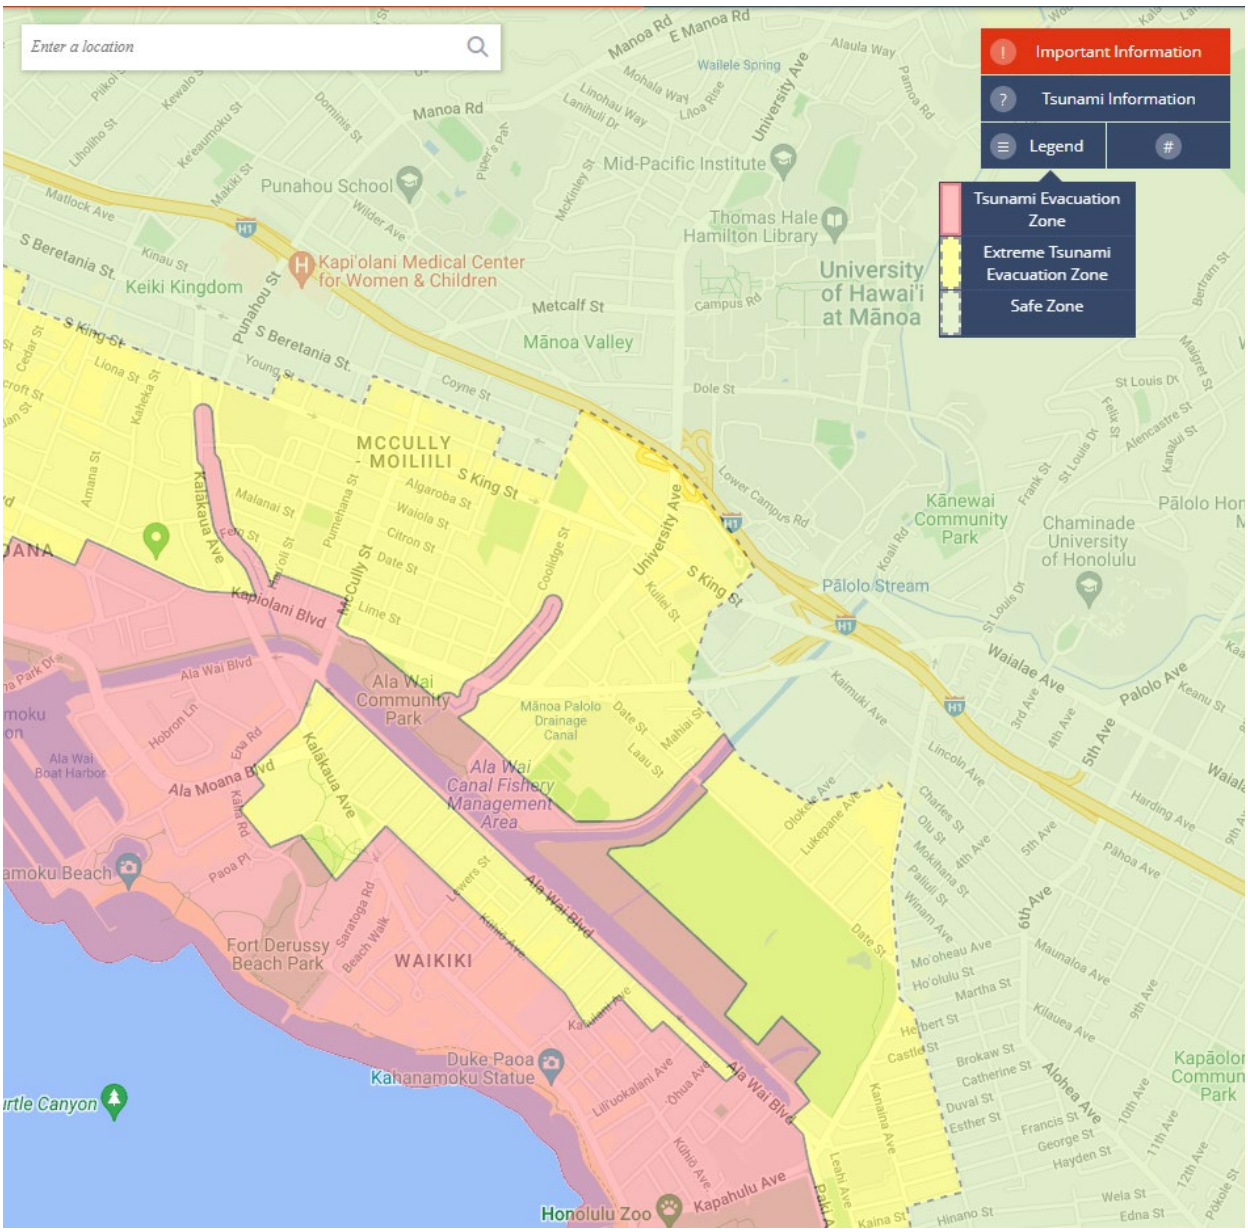

Figure 24: Tsunami Evacuation Zones within the Vicinity of the Ala Wai Watershed.

Alternative 1 also includes the implementation of potential mitigation measures for induced flooding. Potential mitigation measures include nonstructural measures such as dry/wet floodproofing, elevation, and acquisition. The potential nonstructural mitigation measures are generally included in the Nonstructural Alternative, therefore, refer to the impact analysis for Alternative 6 for these measures. The only potential structural mitigation measure under consideration is a pump station(s), although it is highly unlikely due to cost that a pump station will be constructed. Regardless, the potential effects of a pump station on public health and safety are analyzed below. Although the precise location of the pump station(s) is unknown at this time, it is likely to be located along Makiki Stream between Fern Street and the confluence of Makiki Stream with Ala Wai Canal. Because of the urban nature of the general area, short-term minor adverse safety effects on the public (e.g., motorists, bicyclists, and pedestrians) and emergency services could occur during construction of the pump station(s). There is the potential for temporary road closures and/or reduced lanes, but alternate routes would be provided. The construction area would be secured from trespassers and construction worker safety protocols would be followed as prescribed by the Occupational Safety and Health Act (OSHA). Long-term, the operation of the pump station(s) would have negligible adverse impacts on safety since maintenance workers would follow safety protocols as prescribed by OSHA. The operation of the pump station(s) during storm events would have a beneficial impact on public health and safety since it would minimize induced flooding.

Overall, the project is not expected to substantially increase health and safety risks to residents and visitors; decrease access to or functionality of critical infrastructure, or other public facilities including schools; or impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan. Therefore, the project would have a less than significant impact on public health and safety and no mitigation would be required.

Alternative 2B

Less than Significant Impact: In general, the type of project features included in Alternative 2B would have similar construction, operation, maintenance, and mitigation requirements as Alternative 1, such that the nature and degree of potential impacts to public health and safety are generally expected to be similar. Therefore, refer to the analysis under Alternative 1 for Alternative 2B project impacts. It is important to note that Alternative 2B includes more floodwalls than Alternative 1 and specifically around the Ala Wai Canal. Construction, operation, maintenance, and mitigation impacts are generally expected to be similar to those discussed under Alternative 1; however, a discussion specific to potential long-term impacts to interference with an adopted emergency response plan or emergency evacuation plan is discussed below.

Alternative 2B includes additional road closure structures within tsunami evacuation zones due to the alternative including a floodwall around the Ala Wai Canal. As discussed above, road closure structures are used to bridge the gap between floodwalls and are typically assembled prior to the notice of a severe storm event, left in place during a storm event, and removed after completion of the severe storm event. Road closure structures assembled prior to a storm event and during a storm event could physically interfere with an adopted emergency response plan or emergency evacuation plan as they would prevent movement along a roadway where they are located. The road closure structure at Date Street to bridge the gap between the Kaimuki High School and the Ala Wai Golf Course floodwall/earthen berm was discussed under Alternative 1. In addition, there are road closure structures at Kapiolani Boulevard, McCully Street, and Kalakaua Avenue. The Kapiolani Boulevard road-closure structure would prevent passage of evacuees to tsunami safe zones if they were in place at the same time as a tsunami warning was issued (Figure 24). Other nearby alternative throughways include University Avenue, King Street, and Kapahulu Avenue which either connect directly to tsunami safe zones

or direct traffic to H-1. The McCully Street and Kalakaua Avenue road-closure structures would prevent evacuees from Waikiki reaching tsunami safe zones if the road closure structures are in place as the same as a tsunami warning is issued. Other nearby alternative throughways include Ala Moana Boulevard, Ala Wai Boulevard, and Kalakaua Avenue heading south. All of these throughways connect to other throughways allowing evacuees to get to H-1 or tsunami safe zones. Reducing the number of roads that evacuees can take to access tsunami safe zones would increase traffic on the alternative throughways from the Waikiki area. There would be no substantial impact to those outside of the Waikiki area attempting to evacuate. Within the Waikiki area there would be a reduction in the number of evacuation routes from four to three, although it is important to note that one of the remaining evacuation routes would not allow traffic to exit via two directions, only one (i.e., Kalakaua Avenue). Although this would likely increase traffic on these three remaining evacuation routes it is likely to not be a substantial increase. Traffic signage could be placed when road closure structure is assembled to bring awareness to the community that the throughway where the road closure structure is located is temporarily unavailable as a tsunami evacuation route. Traffic signs could also be placed to bring awareness to the community of alternative tsunami evacuation routes.

Overall, the project is not expected to substantially increase health and safety risks to residents and visitors; decrease access to or functionality of critical infrastructure, or other public facilities including schools; or impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan. Therefore, the project would have a less than significant impact on public health and safety and no mitigation would be required.

Alternative 5

Less than Significant Impact: In general, the type of project features included in Alternative 5 would have similar construction, operation, maintenance, and mitigation requirements as Alternative 1 and Alternative 2B, such that the nature and degree of potential impacts to public health and safety are generally expected to be similar. Therefore, refer to the analysis under Alternative 1 and Alternative 2B for Alternative 5 project impacts.

Alternative 6

Less than Significant Impact: Alternative 6 involves temporary construction on existing structures, demolition of structures to be acquired, and construction access for both. During construction, if all safety regulations are followed there would be negligible temporary adverse effects on safety.

There would be long-term minor direct and indirect beneficial effects for safety as a result of this alternative. Elevation and dry floodproofing both aid in adaptation of structures to future flood events due to climate change. Acquisition and demolition will eliminate buildings that are expected to sustain significant damage from future storms and relocate residents to higher ground. In addition, the resulting open space could also help absorb storm floodwaters and potentially help reduce flooding and unsafe conditions elsewhere.

Environmental Commitments

No environmental commitments associated with impacts to public health and safety apply.

Best Management Practices

BMPs used to minimize impacts to public health and safety include:

- Signs depicting road closure structure locations.
- Signs showing alternative tsunami evacuation routes when road closure structures are in place.

3.5.7 Public Services and Utilities

Regulatory Setting

The following federal/state laws or regulations are associated with public services and utilities.

- HRS Chapter 46-11.5 – *Maintenance of Channels, Streambeds, Streambanks, and Drainageways*
- ROH Section 41-26.3 – *Maintenance of Channels, Streambeds, Streambanks, and Drainageways*

Existing Conditions

Public services that are available within the Ala Wai Watershed include police, fire, emergency medical services, public libraries, public schools, and community centers. Utilities that are available within the Ala Wai Watershed include infrastructure for electricity, telecommunications, solid waste, water, and wastewater. Other services include stream channel maintenance. The following is a brief overview of each of these services and utilities.

Police, Fire Protection, and Emergency Medical Services

Police services on the island of Oahu are provided by the Honolulu Police Department (HPD). HPD's headquarters are in downtown Honolulu, just within the western boundary of the watershed. The island is divided into eight patrol districts; the Ala Wai Watershed includes three of these districts, including most of District 1 (Central Honolulu), all of District 6 (Waikiki), and the western half of District 7 (East Honolulu).

In general, fire protection services for the island of Oahu are provided by the Honolulu Fire Department (HFD). The HFD is responsible for multi-mission emergency response for events including fire, emergency medical situations, hazardous material incidents, search and rescue (i.e., for mountain and ocean), motor vehicle accidents, and natural disasters. The island is divided into five battalions containing 44 fire stations. The Ala Wai Watershed includes portions of Battalion 1 and 2, with a total of 7 stations.

The Department of Forestry and Wildlife also has a Fire Management Program, which provides protection for wildlands, including forest reserves, natural area reserves, wildlife and plant sanctuaries, and public hunting areas. Portions of the upper watershed are designated as DOFAW primary response areas. In addition, DOFAW will cooperate with HFD for the protection of other wildlands not within their primary response area, to the extent needed to provide for public safety (DOFAW, 2010).

Emergency medical facilities within the Ala Wai Watershed include Straub Hospital and Kapiolani Medical Center for Women and Children. Straub Hospital is a full-service hospital located near the western boundary of the watershed, in the Ala Moana/Kakaako neighborhood. Kapiolani Medical Center for Women and Children is in lower Makiki, near the border with the Manoa neighborhood. Specializing in care for women and children, it offers a full array of medical services, including a pediatric emergency services and intensive care facilities. Queen's Medical Center, considered to be the primary trauma hospital on the island, is located just outside the western boundary of the watershed.

Public Schools, Cultural Centers, and Community Centers

The Hawaii State Public Library System is the only statewide public library system in the United States. There are 51 branches throughout the six islands of the state. There are four library branches of the Hawaii State Public Library System located within the Ala Wai Watershed. They

are the Library for the Blind and Print Disabled located at 402 Kapahulu Avenue, which provides books and magazines in audio and braille for patrons who are certified as having visual impairment or other physical limitation that prevents them from reading standard printed material. The McCully Moiliili Public Library (2211 S. King Street) which includes the Korean Library Foundation that maintains the largest Korean language collection in the library system. The last two branches within the Ala Wai Watershed at the Manoa Public Library (2716 Woodlawn Drive) and Wakiki-Kapahulu Public Library (400 Kapahulu Avenue).

The Hawaii State Department of Education is a large statewide school district comprised of 257 schools that are divided into seven small districts across the Hawaiian Islands. On the islands of Oahu, there are four smaller districts—Honolulu, Central, Leeward, and Windward. The Ala Wai Watershed is located within the Honolulu District and the Farrington-Kaiser-Kalani Complex. The Farrington-Kaiser-Kalani Complex has approximately 7,433 total students and 931 teachers (HI DOE, 2017). Public kindergarten through twelfth grade schools within the Ala Wai Watershed include: Ala Wai Elementary School, Aliiolani Elementary School, Hokulani Elementary School, Jefferson Elementary School, Kuhio Elementary School, Liholiho Elementary School, Lunalilo Elementary School, Manoa Elementary School, Noelani Elementary School, Palolo Elementary School, Waikiki Elementary School, Jarrett Middle School, Stevenson Middle School, Washington Middle School, Avenue Elementary through High School, Kaimuki High School, Roosevelt High School, and Hawaii School for the Deaf & Blind. Higher education facilities within the watershed include the University of Hawaii at Manoa and Chaminade University of Honolulu.

Cultural facilities within the Ala Wai Watershed include the Manoa Valley Heritage Center. Within the Manoa Valley Heritage Center is Kukaoo Heiau, an ancient agricultural temple originally built centuries ago but restored in 1933. In addition, the Japanese Cultural Center of Hawaii is also located within the Ala Wai Watershed.

Community centers within the Ala Watershed include Hanalei's Cultural Community Center, Kapahulu Center, Maryknoll Community Center, Moiliili Community Center, and Waikiki Community Center.

Electricity and Telecommunications

Hawaiian Electric Company (HECO) is the primary electrical utility provide for the island of Oahu. None of the power plants on the island of Oahu are located within the Ala Wai watershed. HECO's island-wide transmission and distribution system is comprised of various substation facilities and a broad network of power lines (some of which are located underground), with capacities ranging from 12 kilovolt (kV) to 138 kV.

Telecommunication services that are provided throughout the watershed include various radio, cell phone, and internet technologies.

Solid Waste

Solid waste services for the island of Oahu are provide by the City and County of Honolulu ENV. Specific services include drop-off facilities, curbside collection, and recycling. Most residential and general commercial trash is disposed at H-POWER, the City's waste-to-energy plant (located at Campbell Industrial Park). H-POWER processes over 600,000 tons of waste annually, producing approximately 7% of Oahu's electricity. Noncombustible construction and demolition (C&D) debris and industry waste is disposed of as landfill (ENV, 2005). The island's two landfills are located approximately 35 miles west of the watershed.

Water and Wastewater

City and County of Honolulu Board of Water Supply (BWS) manages the municipal water supply and distribution system on the island of Oahu. BWS is responsible for providing water service for consumers, regulating water availability for new developments, and protecting, developing, and conserving the island's water resources. In fiscal year 2014, municipal water use for the island of Oahu totaled approximately 140 million gallons per day (mgd) (BWS, 2014a). For comparison, approximately 61 mgd was consumed within the primary urban core, which is comprised mostly by the Ala Wai watershed (BWS, 2014b).

The City and County of Honolulu ENV is responsible for management of wastewater on the island of Oahu. There are a total of nine wastewater treatment plants (WWTP) in operation; the Ala Wai watershed is serviced by the Sand Island WWTP, located approximately 2 miles west of the watershed. The Sand Island WWTP is the largest plant on Oahu and receives approximately 85% of the island's wastewater, processing more than 60 mgd (ENV, 2010).

Stormwater Drainage

The City and County of Honolulu ENV is also responsible for the island's storm drain system. This system, which is referred to as the Municipal Separate Sewer System (MS4), captures storm water and conveys it directly to streams, canals, and/or the ocean to prevent flooding in developed areas.

Stream Channel Maintenance

HRS Section 46-11.5 mandates that "each county shall provide for the maintenance of channels, streambeds, streambanks, and drainageways, whether natural or artificial, including their exits to the ocean, in suitable condition to carry off storm waters; and for the removal…(of) any debris which is likely to create an unsanitary condition or otherwise becomes a public nuisance." However, the statute specifies that waterways that are owned by the State or by a private entity shall be maintained by their respective owners. A large percentage of the streams are privately owned, with an estimated 150 private landowners along Manoa Stream along (Oceanit, 2008). Section 41-26.3 of the ROH dictates that private owners are responsible for maintaining, dredging, and clearing the stream of any debris, vegetation, silt, or other items of any kind that may interfere with the natural flow of water. However, many private landowners are not aware of this responsibility of the scope of activities that are entailed (Townscape, 2008).

Given the diverse ownership of land, management responsibilities for the waterways are divided amongst many agencies and individuals. Many stakeholders have expressed frustration with the lack of adequate stream channel maintenance, which stems from the complexity of land ownership, with issues including fractured or inconsistent approaches to maintenance by different landowners, limited accessibility, limited resources, and excessive costs.

Significance Criteria

Effects to utilities would be considered significant if the proposed project would result in any of the following:

- Substantially interfere with, or increase the response time of police, fire, or emergency medical services.
- Substantially interfere with, or increase performance objectives for public services such as schools, parks, or other public facilities.
- Permanently disrupt or decrease the level of service for any public utility.

- Require or result in the relocation or construction of new or expanded water, wastewater treatment or storm water drainage, electric power, natural gas, or telecommunications facilities, the construction or relocation of which could cause significant environmental effects.
- Generate solid waste in excess of the capacity of local infrastructure.

Environmental Consequences

No Action Alternative

No Impact: Under the No Action Alternative, the federal flood risk management measures would not be constructed, and as a result, there would be no construction-related impacts to public services and utilities. However, large portions of the watershed (and the associated public services and utilities) would remain vulnerable to increased levels of flooding. Flood-related impacts include increased emergency response requirements by police, fire, and medical teams during flood events. In addition, portions of the utility infrastructure may be subject to flooding (including the sewer and stormwater drainage systems, as well as electrical substations), which could cause widespread service disruptions.

Given the current development and the extensive network of utilities within the watershed, it is assumed that the distribution and scope of public utilities and services would remain relatively constant over the duration of the period of analysis.

Alternative 1

Less than Significant Impact: According to the 2019 Service Efforts & Accomplishments Report for the City and County of Honolulu (CCH, 2019), the average response time for Priority 1 calls (i.e., emergencies and in-progress cases) by the Honolulu Police Department is 7.24 minutes. The average response time for Priority 2 calls (i.e., forgery, fraud, vandalism, weapons, prostitution, drugs, gambling, driving while intoxicated, etc.) by the Honolulu Police Department is 10.04 minutes. Also, according to the 2019 Service Efforts & Accomplishments Report for the City and County of Honolulu (CCH, 2019), the average response time for Honolulu Fire Department Emergency Medical Services for Urban Tier I locales is 8.12 minutes. Similarly, the average fire response time for the HFD is also 8.12 minutes. The average response time for Urban Tier II HFD EMS is about 9.30 minutes, which is also the same average response time for a fire by the HFD. Lastly, the rural average response time for HFD EMS and fire response is about 16 minutes.

During construction of the project, the response times for HPD and HFD are not expected to increase or decrease substantially. Construction personnel would be using area roadways to access the project staging areas in the morning and afternoon and construction vehicles such as haul trucks would sporadically be using the area roadways to access the project staging areas for deliveries and/or pick-ups. None of the project staging areas are located on part of a roadway nor are any roadways expected to be partially closed (e.g., single lane closure) during construction of the project. Therefore, short-term construction of the project would not substantially increase or decrease emergency services response times.

Long-term there could be potential impacts to emergency services response times. Increases in response times would likely occur during large storm events when road closure structures are put in place to span the gap between constructed floodwalls. Roads where road closure structures are located would be impassible prior to a storm event occurring, during the storm event, and for a short time after the event until maintenance can reach the road closure structures and remove them. Although closure of the roads would likely increase emergency

service response times, the increase in response time would likely not be substantially different than it is under the No Action Alternative. Under the No Action Alternative, road closures already occur during storm events due to flooding and cleanup activities post-storm. The emergency response times that are experienced during storm events under the No Action Alternative would likely be similar to the emergency response times that would be experienced under Alternative 1 during and after a storm event. Overall, the construction and operation and maintenance of the project is not expected to substantially interfere with or increase the response time of police, fire, or emergency medical service. Therefore, the project would have a less than significant impact and no mitigation would be required.

Regarding other public services such as schools, parks, or other public facilities, construction of the project could have a short-term impact primarily on parks. Refer to the discussion on potential impacts to parks under Section 3.5.4. Regarding other facilities such as schools, libraries, community centers, etc. short-term construction of the project is not expected to have a significant impact. For the most part, construction activities do not include staging or access/egress through the above areas. The one exception is Kaimuki High school, where construction of a floodwall along the perimeter of the athletic fields would occur. Construction could be phased to minimize disruptions during student arrival and dismissal times. Long-term, the project is not expected to substantially interfere with other public services. Regarding long-term interference with area parks refer to Section 3.5.4. For other facilities such as schools, libraries, community centers, etc. long-term operation and maintenance of the project would not be expected to substantially interfere with these facilities. Again, the only exception is likely Kaimuki High School where a floodwall would be located long-term around the perimeter of the athletic fields. Routine maintenance would likely be able to be phased so that it occurs when school is not in session. However, emergency maintenance/repairs would need to occur as soon as possible, meaning that they could occur while school is still in session. Similarly, when road closure structures are put into place, the road closure structures could interfere with access to Kaimuki High School as well as other facilities located near floodwalls. Although road closure structures could interfere with access to the above facilities, the access to the above facilities would likely not be substantially different than it is under the No Action Alternative. Under the No Action Alternative, road closures already occur during storm events due to flooding and cleanup activities post-storm. Interference to accessing other public service facilities would likely be similar to interference already experienced during storm events under the No Action Alternative. The cause of the interference would be road closure structures instead of flooding, and both alternatives would still require post-storm cleanup activities. Overall, construction, operation and maintenance of the project is not expected to substantially interfere with other public services. Therefore, the project would have a less than significant impact and no mitigation would be required.

Construction of the project does not include new or expanded water, wastewater treatment, electric power, natural gas, or telecommunications facilities which could cause significant environmental effects. The project does include the construction of stormwater detention basins and inlet/outlets to and from these stormwater detention basins which results in the construction of new storm water drainage. The detention basins are located on two community parks and a golf course which are comprised of turf grass. Therefore, construction of these facilities would not cause significant environmental effects. Construction of the project features, in addition to the detention basins, could result in the relocation of utilities. The specific locations of existing utility lines and detailed relocation plans would be identified as part of the design phase. There may be some temporary interruptions in service, as needed to accommodate utility removal/relocation, but the interruptions would be minimized to the extent practicable and adequate notification would be provided, such that these impacts are expected to be less than

significant. Any existing utilities that need to be replaced/relocated during construction, are not expected to cause a long-term impact to the level of service for any public utility. Planned utility relocations being conducted by others would be coordinated and accommodated through the final design phase, to the extent practicable. Long-term, there are no utility requirements expected for the operation and maintenance of the project. As such, the project is not expected to permanently disrupt or decrease the level of service for any public utility nor require the relocation of construction of new or expanded water, wastewater treatment or storm water drainage, electric power, natural gas, or telecommunications facilities, the construction or relocation of which could cause significant environmental effects.

Currently, Oahu is serviced by a single landfill, Waimanalo Gulch Sanitary Landfill. The landfill accepts municipal solid waste, sandblast media, and non-hazardous contaminated soils. The landfill is scheduled for permanent closure in 2028, with the City and County of Honolulu currently evaluating potential sites on Oahu for a new landfill. The following analysis assumes that the Waimanalo Gulch Sanitary Landfill is still in service when the proposed project is constructed; however, the analysis would also apply to any new landfill in operation as the new landfill would likely have the same or higher daily maximum capacity than the Waimanalo Gulch Sanitary Landfill which could be retired by the time the project is constructed. During construction of the project, approximately 203,757.61 cubic yards of material would be excavated for construction of project features. Construction of the project does require fill and the intent is to reuse material excavated on site as fill material for project features. The estimated amount of fill required for the project is 173,957.43 cubic yards of material. Excess excavated material that cannot be reused onsite would be disposed of offsite at the Waimanalo Gulch Sanitary Landfill. This excess material would not be disposed of offsite all at once, but daily. The quantities of material that would be transported to the local landfill for disposal daily would be minor in relation to the capacity of the landfill. Annual maintenance generally would include the excavation of sediments from the detention basins and recovery of trash/debris; however, the quantities removed/recovered and disposed of per day would be nominal in relation to the capacity of the Waimanalo Gulch Sanitary Landfill. Therefore, less than significant impacts associated with solid waste disposal would occur and no mitigation would be required.

Alternative 1 also includes the implementation of potential mitigation measures for induced flooding. Potential mitigation measures include nonstructural measures such as dry/wet floodproofing, elevation, and acquisition. The potential nonstructural mitigation measures are generally included in the Nonstructural Alternative, therefore, refer to the impact analysis for Alternative 6 for these measures. The only potential structural mitigation measure under consideration is a pump station(s), although it is highly unlikely due to cost that a pump station will be constructed. Regardless, the potential effects of a pump station on public health and safety are analyzed below. Although the precise location of the pump station(s) is unknown at this time, it is likely to be located along Makiki Stream between Fern Street and the confluence of Makiki Stream with Ala Wai Canal. Short-term, construction of the pump station(s) would potentially have temporary minor adverse construction-related effects. The pump station(s) does require a reliable source of power for the pump motor drives. The pump station(s) will also include an emergency power supply such as electric power feed from two independent power distribution lines; an on-site standby generator; an adequate portable generator with quick connection; and a stand-by engine drive. The construction of the pump station(s) is not expected to substantially effect public utilities with its need for a power source. Long-term, the operation and maintenance of the pump station(s) would have no impact on public utilities as the pump station would have its own public utility lines.

Overall, Alternative 1 is expected to have short-term minor adverse impacts on public utilities during construction and less than significant long-term adverse impacts to public utilities from operation and maintenance.

Alternative 2B

Less than Significant Impact: In general, the type of project features included in Alternative 2B would have similar construction, operation, maintenance, and mitigation requirements as Alternative 1, such that the nature and degree of potential impacts to public services and utilities are generally expected to be similar. Therefore, refer to the analysis under Alternative 1 for Alternative 2B project impacts. Overall, Alternative 2B is expected to have short-term minor adverse impacts on public utilities during construction and less than significant long-term adverse impacts to public utilities from operation and maintenance.

Alternative 5.3

Less than Significant Impact: In general, the type of project features included in Alternative 5.3 would have similar construction, operation, maintenance, and mitigation requirements as Alternative 1 and Alternative 2B, such that the nature and degree of potential impacts to public services and utilities are generally expected to be similar. Therefore, refer to the analysis under Alternative 1 and Alternative 2B for Alternative 5.3 project impacts. Overall, Alternative 5.3 is expected to have short-term minor adverse impacts on public utilities during construction and less than significant long-term adverse impacts to public utilities from operation and maintenance.

Alternative 6

Less than Significant Impact: There would be minor, short-term to long-term impacts to utility infrastructure with implementation of Alternative 6. Implementation of measures such as elevation and dry floodproofing would likely require local investigations for existing utilities at those locations, such as service lines to individual buildings for gas, water, sewage and in some cases (where lines are underground) power. Telecommunications should not be affected by the nonstructural measures. Elevation of structures is the measure most likely to require utilities investigations, including elevation of local utilities that service individual buildings. Local actions may include raising of HVAC structures, power substation raising, and possibly relocating and/or altering water service lines. Such impacts would be minor, temporary, and limited to individual buildings and, therefore, would not be significant. Overall, there would be short-term negligible to minor adverse impacts to utilities and negligible long-term effects on utilities.

Environmental Commitments

No environmental commitments associated with impacts to public services and utilities apply.

Best Management Practices

No BMPs associated with impacts to public services and utilities apply.

3.5.8 Transportation and Traffic

Regulatory Setting

Regulatory conditions for traffic and analysis are generally dictated by overall transportation industry standards as published by the Federal Highway Authority and the U.S. Department of Transportation. These organizations serve as oversight agencies ensuring the respective regional, state, and local jurisdictions follow the appropriate guidelines and parameters. For traffic analysis parameters, delays are generally considered the leading indicators of traffic flow and operations; the shorter the delay, the better the roadway segment flows, and the

intersections operate. Federal regulations do not dictate specific levels of operation or minimum delays. Instead, it is primarily the local jurisdiction's judgement, supported by the analyst's qualitative calculations, that established the best option.

- City and County of Honolulu's Traffic Standards Manual, 1976
- Subdivision Street Standards, 2001
- Act 54, Session Laws of Hawaii (SLH) 2009
- Bike Plan Hawaii, 2003
- Oahu Bike Plan, 2012
- Oahu Metropolitan Planning Organization Complete Streets Checklist, 2013
- Hawaii Statewide Pedestrian Master Plan, 2013
- City Complete Street Checklist, 2014
- Honolulu Complete Streets Ordinance (ROH Chapter 14, Article 33)
- HRS, Section 264-20, Flexibility in Highway Design; Liability of State, Counties, and Public Utilities

Existing Conditions

A variety of roadways occur within the Ala Wai watershed, ranging from one of the State's primary freeways, to major thoroughfares and collector streets, to local access roads. H-1 (Lunalilo Freeway is one of four freeways on the island of Oahu, providing access between the Ewa district and Hawaii Kai, which constitutes the island's primary urban corridor. It is approximately 27 miles long, of which approximately 4 miles occurs within the Ala Wai watershed. The number of lanes varies throughout the corridor, but within the watershed there are typically three lanes in each direction, not including ramps and auxiliary lanes. The only State Route (SR) within the watershed is SR 92, more commonly referred to as Ala Moana Boulevard, which parallels the shoreline in the western portion of the watershed (DOT, 2008). Other major thoroughfares within the watershed include Beretania Street, King Street, Kapiolani Boulevard, Ward Avenue, Kalakaua Avenue, University Avenue, Waialae Avenue, and Kapahulu Avenue. Most of these roadways serve as collector roads, carrying traffic between areas of activity within the urban district. These roadways are generally oriented in either an east-west direction (Beretania Street, King Street, Kapiolani Boulevard, and Waialae Avenue) or a mauka-makai direction (Ward Avenue, Kalakaua Avenue, University Avenue, and Kapahulu Avenue). The remainder of the transportation network within the Ala Wai watershed is comprised of smaller, local roads, such as those providing access into the residential neighborhoods. With the exception of H-1 and SR 92, all of the roads within the watershed are under the jurisdiction of the City and County of Honolulu Department of Transportation Services (DTS). Traffic conditions vary by location, but in general, many of the major roadways are over capacity during morning and afternoon peak hours, resulting in significant traffic delays.

The City and County of Honolulu DTS operates TheBus and TheHandi-Van public transportation systems. Annual ridership on TheBus is 68,274,031 while the annual ridership for TheHandi-Van is 890,453 (DTS, 2022). The study area is serviced by approximately 12 bus routes (Table 44) as well as nine bus routes which service the University of Hawaii (Table 45). In addition to the public bus transit system, the Waikiki Trolley red line and blue line also operate along roads within the vicinity of Ala Wai Canal.

Table 44: Bus Routes Servicing All or Portions of the Study Area.

Bus Route Number	Route	Type of Route
1	Kaimuki/Kalihi	Frequent Urban Route

Bus Route Number	Route	Type of Route
2	Waikiki/School/Middle	Frequent Urban Route
3	Kaimuki/Salt Lake	Frequent Urban Route
5	Ala Moana/ Manoa	Local Route
6	Pauoa/Woodlawn	Local Route
8	Ala Moana/Waikiki/Makiki	Frequent Urban Route
9	Kaimuki/Pearl Harbor	Local Route
13	Liliha/ Waikiki /University	Frequent Urban Route
14	St. Louis/Maunalani	Local Route
18	Kapahulu/Aina Haina	Local Route
19	Waikiki/Airport/Hickam	Frequent Urban Route
20	Waikiki/Airport/Pearlridge	Frequent Urban Route

Table 45: Bus Routes Servicing the University of Hawaii.

Bus Route Number	Route	Type of Route
80A	Hawaii Kai Park & Ride Express (UH)	Commute Route
83	Wahiawa Town Express	Commute Route
84	Mililani Express/North	Commute Route
84A	Mililani Express/South	Commute Route
85	Windward Express/Kaneohe	Commute Route
86	Windward Express/Haiku	Commute Route
87	Windward Express/Kailua	Commute Route
90	Pearl City Express	Commute Route
94	Villages of Kapolei/Kaupea Express	Commute Route

There are no airports located within the Ala Wai watershed. The nearest airport is the Honolulu International Airport (HIA) which is located approximately 10 miles north of Waikiki.

The Oahu Bike Plan (DTS, 2012) was developed to guide bikeway planning for the entire island of Oahu. It identifies the existing bicycle network and provides recommendations of new facilities as part of a strategy for better integrating bicycling into the transportation system.

Significance Criteria

Effects to transportation would be considered significant if the proposed project would result in any of the following:

- Conflict with a program, plan, ordinance, or policy addressing the circulation system, including transit, roadway, bicycle, and pedestrian facilities.
- Substantially increase vehicle travel times due to increased congestion, delays in traffic movement and circulation, and/or reduced roadway capacity.
- Substantially increase hazards due to a geometric design feature (e.g., sharper curves or dangerous intersections) or incompatible uses (e.g., farm equipment).
- Substantially decrease access to businesses, residences, or public facilities.
- Substantially displace parking and/or cause other significant changes in parking supply.

Environmental Consequences

No Action Alternative

No Impact: Over the period of analysis for this project, it is anticipated that traffic levels could increase, but the transportation resources within the watershed are not expected to substantially change. Under the No Action Alternative, none of the proposed flood risk management measures would be implemented and the anticipated reductions in potential flooding within the watershed would not be realized. As such, none of the construction-related impacts to traffic and transportation resources would occur, but nor would the benefits associated with protecting important roadways during flood conditions.

Alternative 1

Less than Significant Impact with Mitigation Incorporated: Construction of Alternative 1 would require the delivery of construction equipment and materials, as well as the transportation of construction personnel to each of the project locations, which is expected to impact traffic and transportation. Specific impacts that are anticipated include the following:

- Increased traffic congestion and/or reduced circulation when trucks are hauling material to/from a site.
- Increased degradation of existing pavement/condition of roadways, curbs, or intersections from large, heavy construction vehicles and equipment.
- Decreased driver safety because of reduced sight-distance or increased visual hazards associated with construction vehicles.
- Temporary changes in access to businesses, residences, or public facilities in areas adjacent to construction sites.
- Temporary reduction in availability of public, on-street parking because of construction activities.

An overview of the roadways and other transportation resources that are expected to be affected at each project feature location is provided in Table 46.

Table 46: Roadways and Other Transportation Resources Potentially Affected by Proposed Project.

Feature	Summary of Roadways Potentially Affected	Other Transportation Resources Potentially Affected
Kanaha Floodwall	Major Thoroughfares (e.g., Punahou Street and Nehoa Street) Collector Streets (e.g., Mott Smith Drive, Liholiho Street, Kewalo Street, Keeaumoku Street, Makiki Street, Anapuni Street, Wilder Avenue, and Piikoi Street)	
Makiki District Park Detention Basin	Major Thoroughfares (e.g., Punahou Street and Nehoa Street) Collector Streets (e.g., Wilder Avenue, Keeaumoku Street, Makiki Street, Kinau Street, Lunalilo Street, and Waiau Place)	Bus Route 5 (Ala Moana/ Manoa) and Bus Route 18 (Kapahulu/Aina Haina)
Manoa Valley District Park Detention Basin	Major Thoroughfares (e.g., Oahu Avenue, Manoa Road, and East Manoa Road) Collector Streets (e.g., Lowrey Avenue, Olopua Street, and Kahaloa Drive)	Bus Route 5 (Ala Moana/ Manoa) and Bus Route 6 (Pauoa/Woodlawn)

Feature	Summary of Roadways Potentially Affected	Other Transportation Resources Potentially Affected
Woodlawn Drive Floodwall	Major Thoroughfares (e.g., East Manoa Road and Oahu Avenue) Collector Streets (e.g., Woodlawn Drive, Lowrey Avenue, Kolowalu Street, Pamoa Road, Woodlawn Drive, Pamoa Road, and Hipawai Place)	
Koali Road Floodwall	Major Thoroughfares (e.g., Waialae Avenue and South King Street) Collector Streets (e.g., St. Louis Drive, Dole Street, Kanewai Street, Kamakini Street, and Koali Road)	Bus Route 1 (Kaimuki/Kalihi), Bus Route 13 (Liliha/ Waikiki /University), and Bus Route 14 (St. Louis/Maunalani)
Kaimuki High School Floodwall	Major Thoroughfares (e.g., Kapahulu Avenue, Ala Wai Boulevard, and Kapiolani Boulevard) Collector Streets (e.g., Date Street, Olokele Avenue, and Winam Avenue)	Bus Route 3 (Kaimuki/Salt Lake)
Ala Wai Golf Course Detention Basin	Major Thoroughfares (e.g., Kapahulu Avenue) Collector Streets (e.g., Date Street) Other (e.g., Ala Wai Golf Course Drive)	Bus Route 3 (Kaimuki/Salt Lake), and Bus Route 13 (Liliha/ Waikiki /University)

These impacts could significantly increase travel times and/or affect other transportation resources. However, these impacts would be limited to construction, such that they would be temporary in nature. In addition, the contractor would be required to prepare and implement a Transportation Management Plan (EC TT-1). Preparation and implementation of the plan would be coordinated with relevant transportation agencies, including DOT and DTS. With implementation of the plan, it is anticipated that impacts to traffic and transportation resources would be reduced to less than significant.

Once constructed, the project would not permanently displace any transportation facilities, including roadways, bicycle lanes, pedestrian pathways and/or parking. The project would function to reduce the extent of flooding within the Ala Wai watershed and would effectively remove many major thoroughfares and collector streets (as well as small access roads) from the floodplain, including Kapiolani Boulevard, Kapahulu Avenue, Kalakaua Avenue, and Ala Wai Boulevard. By decreasing the potential for flooding of these roadways, the project would provide important benefits, including improved access within and out of the watershed during flood conditions, including routes used for evacuation and flood response activities. During non-flood conditions, operations and maintenance of the proposed project would require the use of trucks and other vehicles (e.g., to remove and dispose of debris, minor repairs, etc.). However, only a minimal number of vehicles would be required typically, and these activities would occur on a periodic basis, such that traffic and transportation resources are not expected to be significant impacted long term.

Alternative 1 also includes potential mitigation measures that would be implemented to minimize induced flooding within the watershed. Nonstructural mitigation measures under consideration include dry/wet floodproofing, elevation, and acquisition. In general, these types of nonstructural measures make up the Nonstructural Alternative, therefore, refer to the impacts analysis under

Alternative 6 for the potential impacts of nonstructural measures on recreation. The only potential structural measure under consideration is a pump station(s), although the cost of construction makes the implementation of this feature as a mitigation measure highly unlikely. Regardless, the following is a discussion of the potential impacts on recreation a pump station(s) might have. Although the location of the pump station(s) is unknown at this time, it would likely be located along Makiki Stream between Fern Street and the confluence of Makiki Stream with the Ala Wai Canal. This general area is highly urbanized with mostly apartments and businesses. During construction, the area around the pump station(s) would be fenced off for public safety. Depending on the location of the pump station and where it would be fenced off, there could be minor temporary impacts to driving, walking, or biking within the vicinity of this area. This would be temporary, though, and would only last the duration of construction. Once the pump station(s) is constructed, the fencing would be removed, and the area would not incur upon transportation and traffic. Similarly, operation and maintenance of the pump station(s) would have no impact on transportation and traffic in the area.

Alternative 2B

Less than Significant Impact with Mitigation Incorporated: In general, the type of project features included in Alternative 2B would have similar construction, operation, maintenance, and mitigation requirements as Alternative 1, such that the nature and degree of potential impacts to public health and safety are generally expected to be similar. Therefore, refer to the analysis under Alternative 1 for Alternative 2B project impacts. It is important to note that Alternative 2B includes more floodwalls than Alternative 1 and specifically around the Ala Wai Canal. Table 47 shows the additional roads/bus routes that would potentially be impacted during project construction specific to the Ala Wai Canal floodwalls.

Table 47: Roadways and Other Transportation Resources Potentially Affected by Ala Wai Canal Floodwalls.

Feature	Summary of Roadways Potentially Affected	Other Transportation Resources Potentially Affected
Ala Wai Canal Floodwalls	Major Thoroughfares (e.g., Ala Moana Boulevard, Kalakaua Avenue, McCully Street, Ala Wai Boulevard, Kapiolani Boulevard, King Street, and Kapahulu Avenue) Collector Streets (e.g., Date Street, Kaimuki Avenue, Laau Street, Hihiwai Street, University Avenue, Kamoku Street, and Mahiai Street) Other (e.g., Iolani School Driveway, Ala Wai Golf Course Drive)	Bus Route 2 (Waikiki/School/Middle), Bus Route 3 (Kaimuki/Salt Lake), Bus Route 8 (Ala Moana/Waikiki/Makiki), Bus Route 9 (Kaimuki/Pearl Harbor), Bus Route 13 (Liliha/ Waikiki /University), Bus Route 19 (Waikiki/Airport/Hickam), and Bus Route 20 (Waikiki/Airport/Pearlridge), Ala Wai Promenade, Ala Wai Park Trail,

Overall, with the implementation of EC TT-1, Alternative 2B is expected to have a less than significant impact with mitigation incorporated on transportation and traffic resources.

Alternative 5.3

Less than Significant Impact with Mitigation Incorporated: In general, the type of project features included in Alternative 5.3 would have similar construction, operation, maintenance, and mitigation requirements as Alternative 1 and Alternative 2B, such that the nature and

degree of potential impacts to public services and utilities are generally expected to be similar. Therefore, refer to the analysis under Alternative 1 and Alternative 2B for Alternative 5.3 project impacts.

Alternative 6

Less than Significant Impact: Alternative 6 involves temporary construction on existing structures and construction access. Staging areas would not directly affect roadways, however, heavy equipment entering and exiting the transportation network could cause temporary, indirect negligible to minor travel delays. During construction, if all safety regulations are followed there would be negligible short-term adverse effects on transportation safety.

Environmental Commitments

The following environmental commitments would be implemented by the contractor during construction activities to further minimize any potential adverse effects to transportation and traffic:

EC TT-1: Construction contractor would be required to prepare and implement a Transportation Management Plan. Measures to be included in the plan are expected to include the following:

- Institute time-of-day restrictions for large, oversized construction vehicles to minimize interference with peak-hour or commute traffic.
- Maintain at least one travel land on roadways to the extent possible; if complete lane closures are required, post adequate signage for potential detours or possible delays, or conduct full lane closures at night.
- Establish temporary increases in lane capacity, as needed (e.g., widen existing shoulders for bypass traffic).
- Provide advance warning and proper roadway signage along potential construction routes to warn motorists, residents, businesses of changes in roadway and traffic-related conditions (e.g., potential vehicles entering and exiting the roadway, etc.).
- Identify safe and reasonable detours, including those needed for pedestrians and bicyclists, and provide adequate notification.
- Provide written, advanced notice to property owners and businesses adjacent to construction areas.
- Use pilot vehicles when slow or oversized/wide loads are being hauled.
- Use flaggers, as necessary, to direct traffic when large equipment is exiting or entering public roads to minimize risk of accidents.
- Provide temporary parking in nearby locations to the extent possible.
- Repair surface damage to local roads used for construction haul routes to pre-construction conditions.

Best Management Practices

No BMPS associated with impacts to transportation and traffic apply.

3.6 Economic Environment

3.6.1 Socioeconomic/Environmental Justice

Regulatory Setting

Relevant federal and state laws/regulations include:

- Executive Order 12898, *Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations*
- Executive Order 13045, *Protection of Children from Environmental Health Risks and Safety Risks*
- Article XI, Section 9 of the Hawaii Constitution (1978)

Existing Conditions

The U.S. Census QuickFacts was queried for demographic data on the State of Hawaii as well as Honolulu County (Table 48) (U.S. Census Bureau, 2022; City and County of Honolulu, 2022).

Table 48: Demographics Within the Study Area.

	Ala Moana/ Kakaako	Palolo	Makiki/ Tantalus	Manoa	McCully /Moiliili	Diamond Head/ Kapahulu	Waikiki	Honolulu County	Hawaii
Population	25,096	12,880	31,434	23,343	27,226	19,769	18,298	979,682	1,420,074
Persons under 18 years	12.6%	17.3%	12.7%	14.4%	13.5%	13.9%	8%	21.3%	21.4%
White	13.7%	13.2%	19.4%	21.0%	14.3%	22.7%	39.8%	37.7%	42.3%
Black or African American	2.1%	0.5%	1.8%	0.8%	1.4%	0.6%	4.3%	2.8%	2.2%
American Indian and Alaska Native	0.0%	0.03%	0.3%	0.0%	0.2%	0.5%	0.0%	0.3%	0.4%
Asian	64.9%	41.8%	51.2%	51.8%	53.6%	49.0%	42.2%	60.8%	56.3%
Native Hawaiian and Other Pacific Islander	3.8%	23.0%	10.7%	4.5%	8.1%	4.5%	3.3%	24.8%	26.3%
Hispanic or Latino	0.0%	5.0%	0.0%	0.0%	0.0%	0.0%	0.0%	10.0%	10.7%
Two or more races	1.0%	13.4%	0.7%	0.6%	1.5%	0.5%	0.9%	22.8%	24.2%
25+ High School or Higher	88%	87%	90.5%	95%	88%	89%	92%	92.4%	92.5%
25+ BA or Higher	34%	29%	37%	53%	31%	28%	33%	36.2%	34.3%
Median Household Income	$68,200	$59,792	$63,769	$83,946	$61,187	$78,445	$88,000	$87,722	$88,005
Persons in poverty	10.8%	7.5%	10.7%	11.5%	16.4%	6.9%	16.5%	8.0%	10.2%

Significance Criteria

Effects to socioeconomics and environmental justice would be considered significant if the proposed project would result in any of the following:

- Substantially reduce employment opportunities or income levels in the area.
- Disproportionately affect any particular low-income or minority group.
- Disproportionately endanger children in areas within or near the action area.

Environmental Consequences

No Action Alternative

As discussed in above, the demographics of the alternative action area generally reflects that of the island-wide and state-wide population, except that the McCully/Moiliili and Waikiki neighborhoods contain a substantially greater percentage of people with an income below the poverty level. In addition, the median age throughout the watershed is greater than that of the island or state, which is indicative of a high percentage of elderly residents; this trend is expected to continue in the future, as Hawaii's population continues to age. Without implementation of the proposed flood risk management project, a large portion of the Ala Wai watershed (including the lower income population in much of the McCully/Moiliili and Waikiki neighborhoods, as well as a percentage of the elderly population) would remain within the 1% AEP floodplain and would continue to be within at risk of catastrophic flooding. In addition, a total of 11 schools (including University of Hawaii at Manoa), as well as libraries, community centers and other social facilities would continue to be at risk. These conditions are not expected to significantly change over the period of analysis.

Alternative 1

Less than Significant Impact: Short-term, the construction of Alternative 1 is not expected to substantially reduce employment opportunities or income levels in the area. During construction, skilled and unskilled labor would be necessary to construct the project which may in turn temporarily increase employment opportunities in the area. Long-term, the operation of the project is passive meaning labor above the existing condition would not be necessary. Therefore, long-term there would not be a substantial increase in employment opportunities, nor would there be a substantial decrease in employment opportunities within the alternative action area.

Regarding environmental justice, Executive Order 12898 (Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations) states that federal agencies are responsible to conduct their programs, policies, and activities that substantially effect human health of the environment in a manner that ensures that such programs policies, and activities do not exclude persons from participation in, or deny persons the benefits of, or subject persons to discrimination under such programs, policies, and activities because of their race, color, or national origin. USEPA's environmental justice (EJ) mapping and screening tool was used to query the alternative action area. The EJScreen tool was used to ascertain if Alternative 1 would have a disproportionate adverse impact on a minority population, low-income population, or child population (i.e., persons under five years of age). According to EJScreen data, there is not a significantly different under age 5 population within the alternative action area when compared to the State of Hawaii or the U.S. Percentage of the population under 5 within the study area is approximately 4% which is less than the State average and U.S. average of 6% (Figure 25). Therefore, since the percentage of the population under 5 within the alternative action area is less than the percentage of the population under 5 within the State and the U.S., implementation of Alternative 1 would not have a disproportionate impact to this population.

Regarding a low-income population, approximately 24% of the population within the alternative action area are low-income. When compared to the State and the U.S., this percentage is slightly higher than the average percentage for the State (i.e., 22%), but lower than the average percentage for the U.S. (i.e., 30%). Since the percentage of the population that is low-income within the alternative action area is similar to the State and less than the U.S., implementation of Alternative 1 would not have a disproportionate impact on a low-income population.

Regarding a minority population, approximately 82% of the population within the alternative action area are people of color. This is slightly higher than the average percentage for the State of Hawaii (i.e., 78%) and significantly higher than the average percentage for the U.S. (40%). Since the percentage of the population that is considered a minority is greater than 50%, and is significantly higher than the average percentage for the U.S., a minority population is considered present within the alternative action area. Therefore, implementation of Alternative 1 has the potential to disproportionately impact a minority population. However, the objective of the project is to reduce flood risk and flood impacts within the alternative action area. By reducing flood risk and flood impacts, implementation of Alternative has the potential to have a beneficial impact on a minority population.

Alternative 1 also includes potential mitigation measures that would be implemented to minimize induced flooding within the watershed. Nonstructural mitigation measures under consideration include dry/wet floodproofing, elevation, and acquisition. In general, these types of nonstructural measures make up the Nonstructural Alternative, therefore, refer to the impacts analysis under Alternative 6 for the potential impacts of nonstructural measures on recreation. The only potential structural measure under consideration is a pump station(s), although the cost of construction makes the implementation of this feature as a mitigation measure highly unlikely. Regardless, the following is a discussion of the potential impacts on recreation a pump station(s) might have. Although the location of the pump station(s) is unknown at this time, it would likely be located along Makiki Stream between Fern Street and the confluence of Makiki Stream with the Ala Wai Canal. The average median household income in this general area ranges from < $50,000 to $70,000 annually. Although in an area with an average median household income less than the average median household income by census tract (i.e., $77,661); the general area where the pump station(s) could be located doesn't contain many households because it is near the Ala Moana Center. The minority population in this general area ranges from 1,200 to 6,000. Census tracts with the highest minority populations are located more in the upper watershed; therefore, the location of the pump station would not disproportionately adversely affect a minority community. The pump station is not expected to have disproportionately substantial adverse impacts either short-term or long-term to a low-income or a minority population. Ultimately, the pump station would minimize induced flooding which would have a long-term beneficial effect on for the communities located along lower Makiki Stream.

Overall, implementation of Alternative 1 could have a temporary increase in construction jobs available during the construction of the project as well as have a beneficial impact on a minority population. Therefore, the proposed project would have a less than significant impact on socioeconomics / environmental justice and no environmental conservation measures are proposed.

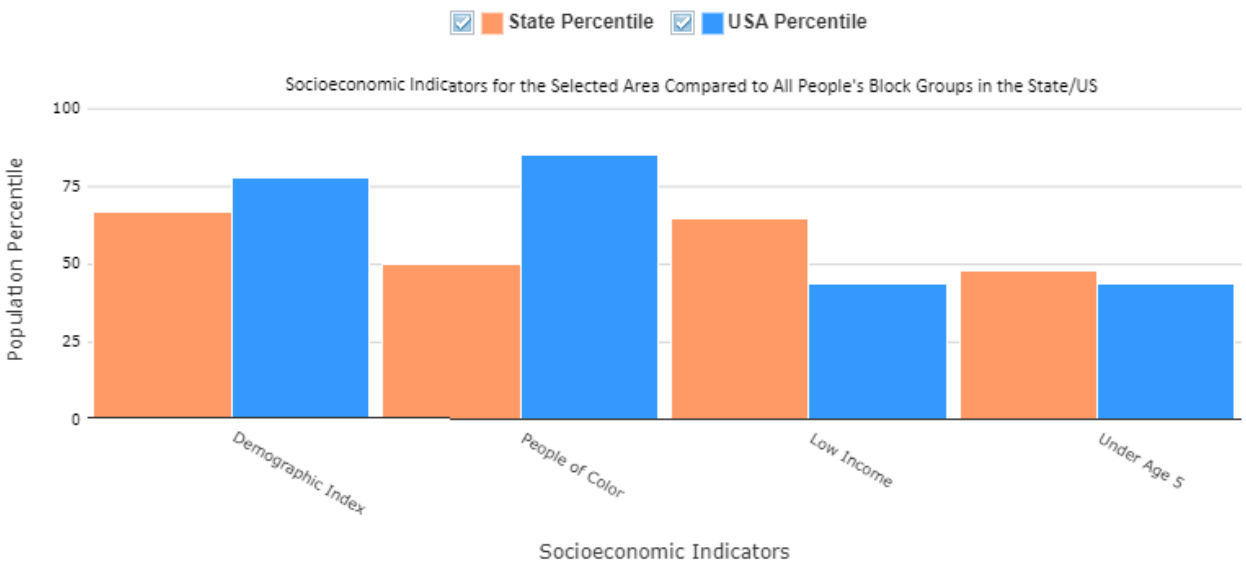

Figure 25: EJScreen Graph Depicting Socioeconomic Indicators within the Ala Wai Watershed

Alternative 2B

Less than Significant Impact: In general, the type of project features included in Alternative 2B would have similar construction, operation, maintenance, and mitigation requirements as Alternative 1, such that the nature and degree of potential impacts to socioeconomics / environmental justice are generally expected to be similar. Therefore, refer to the analysis under Alternative 1 for Alternative 2B project impacts.

Alternative 5

Less than Significant Impact: In general, the type of project features included in Alternative 5 would have similar construction, operation, maintenance, and mitigation requirements as Alternative 1 and Alternative 2B, such that the nature and degree of potential impacts to socioeconomics / environmental justice are generally expected to be similar. Therefore, refer to the analysis under Alternative 1 and Alternative 2B for Alternative 5 project impacts.

Alternative 6

Less than Significant Impact: Alternative 6 involves construction on existing upland structures and construction access and staging. Construction staging areas would be directly co-located with the affected structures.

Elevation and Floodproofing

Approximately 43 residences located throughout Honolulu would be eligible for elevation or raising of homes. Elevation of structures would apply only to residences, would be voluntary for property owners, and would have a beneficial effect on socioeconomics in the form of less damage from flooding. However, structural elevations may cause daily inconvenience to all, and special hardships to the elderly and handicapped. Floodproofing treatments would be done for approximately 1501 public, commercial, and multi-unit housing facilities.

For elevation, temporary relocation and/or restriction of use by residents and businesses would be necessary during construction. Because elevations and floodproofing are voluntary, property owners would not receive temporary relocation aid; however, tenants occupying affected

residences would be eligible for the aid under the Uniform Relocation Assistance Act (URA). Temporary relocations are anticipated to be difficult and expensive due to the number of temporary relocations and the scarcity of housing noted by the City and County of Honolulu. Time spent moving also would cause some, including some low-income households, to miss days of work and income. Temporary relocation during construction also could present special hardships to the elderly, handicapped, minority, or low-income people, for whom moving may be more burdensome, and relocation options may be more limited. Also, restricted use of individual residences and businesses during construction would be an adverse social impact. Therefore, temporary displacement during construction could be a short-term significant adverse impact. The assistance provided pursuant to the URA would help offset these impacts. In addition, construction would need to be phased and timed to ensure that adequate lodging is available, and neighborhoods done simultaneously, if possible.

As stated above, approximately 43 residences would be eligible for elevation or raising of homes. Elevation would be voluntary for all residence owners; and both homeowners and renters would be forced to move temporarily while the elevation construction is accomplished. Residential structures were identified for elevation based on an assessment of which measures produced the most economic benefit. The economic modeling and analysis completed in this study compared the reduction in damage, or economic benefit, provided by elevation and acquisition for each structure at risk to flooding, to the cost to implement that measure. However, Alternative 6 must be compliant with the Uniform Relocation Assistance and Real Property Acquisition Act (URA) which provides protections and benefits to residents affected by acquisition or elevation of their residence.

In accordance with the Environmental Justice EO, USACE has determined that there are potentially significant adverse short-term impacts, as well as significant long-term beneficial effects on disadvantaged minority and low-income populations.

Thousands of residences within low or low-to-moderate income dominated census block groups would be eligible for residence elevation. It should be noted that this does not mean that all residences located in a low or low-to-moderate income dominated census block group are low income and/or minority populations. It means that the majority of the population within that block meets that description. It is also important to note that there also may be affected disadvantaged individuals throughout Honolulu County who do not necessarily reside in a low or low-to-moderate income block group.

Affected residents would be compensated through relocation to comparable residences and provided relocation aid subject to the URA. For elevation, because this measure is voluntary no relocation reimbursements would be anticipated under the URA for homeowners. However, an exception to paying relocation expenses exists when there is an eligible tenant in the property, and the tenant (rather than the property owner) is displaced to accomplish the voluntary measure benefitting the property owned by the lessor. In this case, such tenants may receive relocation benefits. Given that many low-income and minority families are tenants, this would help mitigate the adverse effect on those populations. Regarding floodproofing, dry floodproofing includes sealing all opening below a certain elevation to prevent floodwaters from entering a structure. The maximum height a structure can be dry floodproofed is three feet above ground elevation due to engineering constraints. Structure owners would have to place the barriers prior to a storm, but once placed, damages could be reduced significantly. Wet floodproofing is a strategy where uninhabited space of a structure are intentionally allowed to flood.

Eligible tenants temporarily locating are reimbursed for the cost of temporary alternate housing, meals, and incidentals (such as laundry services), and the fees for disconnection and connection of utilities at the temporary residence. Alternate housing could be hotels or apartments, depending upon availability in the community. All temporary housing costs require advance approval by the NFS after first obtaining the prior written approval of USACE. General Services Administration (GSA) per diem rates are the basis of allowable hotel reimbursement. Apartment costs are on market rents.

All conditions of temporary relocation must be reasonable. Any residential tenant who temporarily relocated for more than one year must be offered permanent relocation assistance, which may not be reduced by the amount of any temporary relocation assistance previously provided. At a minimum, tenants shall be provided the following: reimbursement for all reasonable out-of-pocket expenses incurred in connection with the temporary relocation, including the cost of moving to and from the temporarily occupied housing, and any increase in monthly rent or utility costs at such housing. Tenants are entitled to receive relocation advisory services as well, including reasonably advance written notice of the following:

- Address of the suitable decent, safe, and sanitary dwelling to be made available for the temporary period;
- Terms and conditions under which the tenant may lease and occupy a suitable decent, safe, and sanitary dwelling in the building/complex upon completion of the project;
- Provisions of reimbursement for all reasonably out of pocket expenses incurred in connection with the temporary relocation as noted above; and
- In addition to relocation advisory services, displaced tenants may be eligible for other relocation assistance including relocation payments for moving expenses and replacement housing payments for the increased costs of renting or purchasing a comparable replacement dwelling.

The temporary displacement during construction could be potentially significant, due to the number of temporary relocations and the scarcity of housing noted by Honolulu County. Work would have to be phased such that there was adequate temporary housing for all affected residents. It is intended that phasing would be grouped such that whole neighborhoods could be done simultaneously, to minimize ingress/egress conflicts during construction.

Once construction is complete, residences would be permanently made more resilient to flooding. Elevations could present special hardships to the elderly, handicapped, minority, or low-income people for whom moving may be more burdensome. Elevation heights (new foundation heights) would range from three to 12 feet, with an average of about nine feet. Some homes May require an elevator or lift for the disabled. Elevations also could cause individuals to have to miss days of work during the process, which could adversely affect their families' income Over a thousand low and low-to-moderate income households would be subject to the temporary impact of being relocated during the elevation of their homes. This could cause significant temporary effects. One mitigating factor is that elevation is a voluntary measures; property owners may choose not to take advantage of elevation. However, if the residents are renters, then they would be subject to the decisions of the property owners. Another mitigating factor is that tenants would quality for temporary relocation costs reimbursement. Also, the disruption would be temporary; they could return to the same residences so their communities would not be permanently disrupted. Therefore, the elevation measure would not cause significant adverse long-term effects on any disadvantaged populations. There would be beneficial long-term effects for elevation in that resident relocated to areas would be less susceptible to flood damage in the form of improved flood risk management.

Alternative 6 would result in fewer flood damages to structures and an overall improvement of socioeconomic resilience through the ability of the population to resume normal life after a coastal storm, by keeping infrastructure functional for longer. This would be a significant benefit as critical infrastructure includes utilities, emergency services, and other essential elements of daily life. Short-term indirect and direct adverse effects would result from construction noise and presence and use of heavy equipment in residential and commercial structures. A beneficial temporary socioeconomic effect would be that additional construction work would support jobs locally or bring workers into the area resulting in a negligible to minor economic benefit.

Environmental Commitments

No environmental commitments associated with impacts to socioeconomics / environmental justice apply.

Best Management Practices

No BMPS associated with impacts to socioeconomics / environmental justice apply.

3.7 Cumulative Effects

A cumulative impact is the impact on the environment which results from the incremental impact of the proposed action when added to other past, present, and reasonably foreseeable future actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time in the study area. Those actions could be undertaken by various agencies (federal, state, or local) or private entities. A discussion of cumulative impacts resulting from actions and projects that are proposed, under implementation, or reasonably anticipated to be implemented in the near future is required.

Cumulative environmental impacts are most likely to arise when a relationship exists between a proposed action and other projects expected to occur in a similar location, time period, and/or involving similar actions. Project in proximity to the proposed action would be expected to have more potential for a relationship that could result in potential cumulative impacts than those more geographically separated. Temporary and geographical limits for the proposed action must be established to frame the cumulative impacts analysis. These limits can vary by the resources that are affected. The temporal limits for assessment of this impact would initiate with the construction of the Ala Wai Canal in 1920 and end 50 years after construction of a proposed project is complete in 2077. The geographical boundaries for this discussion of cumulative impacts would be broadened to consider the effects beyond the proposed project. The geographic extent is considered to be the Ala Wai watershed.

Past and Present Actions within the Ala Wai Watershed

It has been estimated that the area comprising the Waikiki District once supported approximately 2,000 acres of coastal wetlands. The streams emerging from Manoa, Palolo, and Makiki valleys flowed parallel to one another before dispersing into multiple smaller waterways which meandered through the coastal wetlands before entering the ocean. The Ala Wai Canal was constructed in the 1920s (due to health concerns over mosquitoes and a desire to more fully develop the Waikiki District). Dredged material was used to fill the wetlands, thus allowing these areas to be developed for residential and commercial purposes. Over the next several decades, various stream channelization projects were completed in response to flooding; these included joining and channelization of Manoa and Palolo streams to form the Manoa-Palolo Drainage Canal, as well as channelization of extensive lengths of Makiki and Palolo streams. Upper portions of the watershed, which historically supported a dense forest with a variety of native species, were also significantly altered. Harvesting of native woods for trade and cattle

grazing in the late 1800s led to deforestation of the upper valleys (Griffith, 1902). Subsequent reforestation efforts, first in an effort to protect Honolulu's water supply and later, in an attempt to establish a timber supply, replaced the once native forest with a patchwork of fast-growing, introduced species (Ziegler, 2002). The introduction of pigs also have a deleterious impact on many endemic species and the biological composition of the forest ecosystem (Mueller-Dombois, 1981). These changes over time provide context for the consideration of cumulative impacts.

Reasonably Foreseeable Actions within the Ala Wai Watershed

Table 49 provides an overview of reasonably foreseeable actions within the Ala Wai Watershed. The effects of the actions listed in the table were considered in combination with the degree and timing of the potential adverse and beneficial effects of the proposed alternatives to determine the types and significant of potential cumulative effects. For this analysis, implementation of the project is considered cumulatively significant if, in concert with other past, present, or reasonably foreseeable future actions, it would exacerbate the declining status of an identified resources (a resource that is already adversely affected) or create a condition in which an effect is initially minor but is part of an irreversible declining trend.

Table 49: Reasonably Foreseeable Actions within the Ala Wai Watershed.

Project Name	General Location	Construction Period	Description
Ala Wai Small Boat Harbor Vision Report	Ala Wai Small Boat Harbor	Waikiki	A team of faculty in the University of Hawaii Community Design Center, School of Architecture, and the Department of Urban and Regional Planning were commissioned by Hawaii's Department of Land and Natural Resources, Division of Boating and Ocean Recreation to create a concept/vision plan for the Ala Wai Small Boat Harbor and generate a conceptual cost estimate for the vision plan. The purpose was to offer insight for future requests for proposals for the harbor. The Vision Report summarizes the process and outcomes of the project. Drawing on the findings from community engagement facilitated by DTL in 2017, DOBOR's Strategic Plan completed in 2019, and a guided site visit with Senator Sharon Moriwaki and the AWSBH Working Group, the team prepared two concepts for the harbor that they shared with key stakeholders to gather feedback. The Vision Report proposals did not include feasibility assessments.
Ala Moana Boulevard Elevated Pedestrian Walkway	1050 Ala Moana Blvd.	Kakaako	The project includes construction of an elevated pedestrian bridge over Ala Moana Boulevard between the intersections of Ward Avenue and Kamakee Street. The busy intersection connects to Ward Village, Kewalo Basin Harbor, and Ala Moana Beach Park. The project is currently under construction. Construction is anticipated to be completed by October 23, 2023.

Project Name	General Location	Construction Period	Description
Ala Pono (Ala Wai Bridge) Project, Honolulu District, Oahu Island, Hawaii	Ala Wai Canal between Ala Moana Boulevard and Manoa/Palolo Stream	Waikiki, McCully, and Moiliili	The proposed project consists of a new pedestrian and bicycle bridge that would span the historic Ala Wai Canal, improving access for people traveling by foot or by bicycle across the Ala Wai Canal between Ala Moana Boulevard and the Manoa/Palolo Stream and would connect the Waikiki, McCully, and Moiliili neighborhoods; businesses; parks; schools; and recreational activities. The project's goal is to improve multimodal network connectivity and enhance public safety for people walking and bicycling. The proposed project is consistent with numerous regional and area plans that have been developed in the last two decades, particularly fulfilling part of the broader Honolulu Complete Streets Program, which implements projects to improve safety, accessibility, and comfort for all people walking, bicycling, accessing transit, and driving.
Ala Wai Boulevard Complete Streets Project	Ala Wai Blvd from Kalakaua Ave. to Kapahulu Ave.		The purpose of the Ala Wai Boulevard Complete Streets project is to make the street safer for everyone, including those walking, using a wheelchair, on a bike, riding transit, and in a car. Proposed improvements include: two-way protected bikeway; curb extensions; additional pedestrian crossings; pedestrian crossing beacons; speed limit reduction to 25 mph; lighting improvements; and time-of-day parking changes.
Kapiolani Boulevard: Honolulu Urban Core Complete Streets Project	Kapiolani Blvd. between South Street and King/Waialae intersection.	2022 estimated construction timeline	The proposed project includes full right-of-way reconstruction along Kapiolani Boulevard. Includes crossing Manoa-Palolo Canal.
Kapiolani Boulevard: Honolulu Urban Core Complete Streets Project	Kapiolani Blvd. between Ward Ave. and King/Waialae intersection.	2019 estimated construction timeline	The proposed project includes interim repaving of Kapiolani Boulevard. Includes crossing Manoa-Palolo Canal.

Project Name	General Location	Construction Period	Description
South King Street: Honolulu Urban Core Complete Streets Project	King Street Corridor between South Street and the Waialae/Kapiolani Intersection	2022 estimated construction timeline	The proposed project includes pedestrian crossing safety improvements, curb extensions, reserve-in angle parking, and a land reconfiguration to address speeding issues while maintaining capacity. Includes crossing Manoa-Palolo Canal.
University, McCully, & Metcalf Complete Streets Project	University Avenue between Maile Way near UH Manoa and Hihiwai Street just before the Ala Wai Canal; McCully Street from Beretania Street to the intersection with Kalakaua Avenue; and Metcalf Street between University Avenue and McCully Street.		
Kuhio Avenue Bus Priority Lanes Complete Streets Project	Kuhio Ave. from Olohana Street to Kapahulu Ave.	Late 2023 estimated construction timeline	The proposed project is a bus-priority project. The proposed project includes bus-priority lanes on Kuhio Avenue which will make more effective use of limited right-of-way space in the dense Waikiki neighborhood. The intent of the project is to reduce operational delays due to traffic congestion for buses in Waikiki. The proposed improvements will increase the speed of buses and enhance the rider experience, making buses more reliable, affordable, and convenient way to travel for local residents, employees, and visitors in Waikiki. The bus-priority lane will be limited to City buses, private bus carriers, bicyclists, and right-turning vehicles at designated areas.
Kalakaua Avenue Road Rehabilitation Project	Kalakaua Ave. from Olohana St. to Monsarrat Ave.; and Kalakaua Ave. from	June 2023 – March 2023	The project includes the reconstruction of asphalt roads, concrete curbs and gutters, and the installation of vehicle detector loops. The project also includes upgrading the Barnes Dance crossings (i.e.,

Project Name	General Location	Construction Period	Description
	Dillingham Fountain to Poni Moi Road.		All-Way Crossing) with improved striping at Royal Hawaiian Avenue, Seaside Avenue, Kaiulani Avenue, Liliuokalani Avenue, and Paoakalani Avenue. The proposed project will also make safety and comfort improvements to the existing bike lane on Kalakaua Avenue.
Arrillaga Student Center	Iolani School Campus	Tentatively Summer 2024 – Winter 2025	The Arrillaga Student Center will replace the existing student center on campus. The proposed project includes the construction of a large indoor, two-story dining and social gathering space; fully equipped commercial kitchen and food storage; wellness center; campus store; faculty & staff lounge; residential life space for students to relax and interact; additional office and storage spaces; large roof space for photovoltaic panels to power the center; new 6th grade community (i.e., eight new classrooms and outdoor learning space); eight new upper school classrooms; entry courtyard connecting to a newly designed chapel garden; expansive covered and open-air outdoor eating and gathering spaces; and rooftop event and gathering spaces with stunning, unobstructed views of Diamond Head and Waikiki skyline.
1538 Kapiolani Tower	1538 Kapiolani Blvd.	Ala Moana	A mixed-use development including 311 market-rate residential for-sale units, plus 101 off-site affordable residential rental units, and 8,711 square feet of commercial space. The project will allow heights up to 400 feet and density up to a 10.0 floor area ratio. Proposed project is currently under city council review.
Ala Moana Plaza	451 Piikoi Street and Ala Moana Blvd.	Ala Moana	A mixed-use development including 459 market-rate residential rental units, 124 affordable residential rental units, and 1,570 square feet of commercial space. The project will allow heights up to 400 feet and density up to a 7.0 floor area ratio. The

Project Name	General Location	Construction Period	Description
			proposed project has received approval for construction by the City Council; however, construction has not commenced.
The Park on Keeaumoku	805, 815, 819, 835, 903, 905, 915, and 919 Keeaumoku Street and 1519 Liona Street.	Ala Moana	A mixed-use development including 818 market-rate residential units, 146 affordable residential units, 88,000 square feet of commercial space, 26,000 square feet of public park/plaza space, and a community center. The project will allow heights up to 400 feet and density up to a 7.0 floor area ratio. The proposed project is currently under construction.
The Sky Ala Moana	1388, 1400, and 1420 Kapiolani Blvd.	Ala Moana	A mixed-use development including 300 condo-hotel units, 390 market-rate residential units, 84 affordable residential units, and 15,000 square feet of commercial space. The project will allow heights up to 400 feet and density up to a 10.0 floor area ratio. The proposed project is currently under construction.
1500 Kapiolani	1460, 1470, 1488, and 1500 Kapiolani Blvd, and at 611 Keeaumoku Street	Ala Moana	A mixed-use development including 444 condo-hotel units, 6 residential units, 78 affordable rental units, and 8,700 square feet of commercial space. The project will allow heights up to 400 feet and density up to a 9.2 floor area ratio. The proposed project has received City Council approval, but construction has not commenced.
Hawaii City Plaza	710 Sheridan Street	Ala Moana	A mixed-use development including 130 market-rate residential units, 33 affordable residential units, and 10,000 square feet of commercial space. The project will allow heights up to 250 and density up to a 5.0 floor area ratio. The proposed project has received City Council approval, but construction has not commenced.
Manaolana Place	1685, 1687, 1689, 1691, and 1695 Kapiolani Blvd., 508 and 512 Atkinson	Ala Moana	A mixed-use development including 125 hotel units, 109 residential units, 12,300 square feet of commercial space, and 4,900 square feet of public plaza space. The project will allow heights up to 400 feet and density up to a 10.0 floor area ratio. The

	Drive, and 1674 and 1676 Kona Street		proposed project has received City Council approval, but construction has not commenced.

Analysis of Cumulative Impacts

The assessment below focuses on addressing the following: (1) the area(s) in which the effects of the alternatives would be felt; (2) the effects that are expected in the area(s) from the alternatives; (3) past, present, and reasonably foreseeable future actions that have or that are expected to have impacts in the same area; (4) the impacts or expected impacts from these other actions; (5) and the overall impact(s) that can be expected if the individual impacts are allowed to accumulate.

There is one project listed in Table 49 that is located within the Ala Wai Canal and the immediate project footprint of the proposed project. The project is the Ala Wai Bridge Project, Honolulu District, Oahu Island, Hawaii.

The Ala Wai Bridge Project includes a new pedestrian and bicycle bridge that would span the historic Ala Wai Canal, improving access for people traveling by foot or by bicycle across the Ala Wai Canal between Ala Moana Boulevard and the Manoa/Palolo Stream and would connect the Waikiki, McCully, and Moiliili neighborhoods; businesses; parks; schools; and recreational activities. The project's goal is to improve multimodal network connectivity and enhance public safety for people walking and bicycling. The proposed project is consistent with numerous regional, and area plans that have been developed in the last two decades, particularly fulfilling part of the broader Honolulu Complete Streets Program, which implements projects to improve safety, accessibility, and comfort for all people walking, bicycling, accessing transit, and driving. Construction of the proposed project is expected to take approximately four years. The potential month and year of project construction initiation is unknown at this time; therefore, the proposed project could overlap with the Ala Wai Bridge Project.

Based on an analysis of the potential effects of the proposed project, the other past, present, and reasonably foreseeable future actions listed in Table 49 could cumulatively impact a variety of resources. Each of these areas is briefly described below.

Climate and Climate Change: The proposed project in combination with other past, present, and reasonably foreseeable future actions would not significantly impact climate and/or climate change. Emissions from construction related to the proposed project and past, present, and reasonably foreseeable future actions identified in Table 49 would be temporary, localized to the construction sites identified for the cumulative projects, and would be a small fraction of GHG emissions produced annually on Hawaii. If construction of other projects identified above and the proposed project occurs at the same time, collectively they are not anticipated to exceed GHG emission thresholds due to the implementation of BMPs which can be used to decrease GHG emissions from diesel engines.

Geology, Seismicity, and Soils: The proposed project in combination with other past, present, and reasonably foreseeable future actions would not significantly impact geology, seismicity, and/or soils. Construction of the proposed project would temporarily expose soils that could be subject to erosion by water and wind. Similarly, past, present, and reasonably foreseeable future actions identified in Table 49 could also temporarily expose soils during construction activities that could be subject to erosion. If construction of other projects identified above and the proposed project occurs at the same time, collectively they are not anticipated to expose soils to such a degree that there would be substantial erosion. In addition, the implementation of BMPs during construction activities to minimize potential soil erosion impacts would be used. Long-term, temporarily disturbed areas that are part of the proposed project would be seeded to prevent erosion and it is anticipated that this would occur for past, present, and reasonably foreseeable future actions as well.

Air Quality: The proposed project in combination with other past, present, and reasonably foreseeable future actions would not significantly impact air quality. Emissions from construction related to the proposed project and past, present, and reasonably foreseeable future actions identified in Table 49 would be temporary, localized to the construction sites identified for the cumulative projects, and would not be expected to greatly exceed current thresholds. If construction of other projects identified above and the proposed project occurs at the same time, collectively they are not anticipated to exceed current emissions thresholds due to the need to implement BMPs.

Groundwater Resources: The proposed project in combination with other past, present, and reasonably foreseeable future actions would not significantly impact groundwater resources. Construction and maintenance of the proposed project along with the construction of past, present, and reasonably foreseeable future actions could have temporary, localized impacts to groundwater quality if inadvertent spills of petroleum type products associated with use of heavy construction equipment were to occur. However, if construction of other projects identified above and the proposed project occurs at the same time, collectively they are not anticipated to have a significant impact on groundwater quality due to the implementation of BMPs to minimize the risk of inadvertent spills. Long-term, the construction of the proposed project along with the construction of past, present, and reasonably foreseeable future actions could have localized impacts to groundwater recharge with the addition of impervious surfaces. However, the proposed project limits the construction footprint to only the area required for construction of flood risk management features and along with past, present, and reasonably foreseeable future actions is not anticipated to have a significant cumulative adverse effect on groundwater recharge.

Surface Water Resources: The proposed project in combination with other past, present, and reasonably foreseeable future actions would not significantly impact surface water resources. Construction of the proposed project along with the construction of past, present, and reasonably foreseeable future actions could have temporary, localized impacts to surface water resources due to the construction of inlet and outlet structures associated with the floodwalls and the Ala Wai Golf Course detention basin. None of the features would permanently obstruct or change the course of a waterway or modify the existing floodplain, but would include the minor placement of fill within waters of the U.S. Operation of the proposed project could have a minor beneficial effect on surface water resources as the Ala Wai Golf Course detention basin could reduce peak flows during storm events which in turn could reduce erosion rates and provide some degree of benefit to channel stability. Collectively, the proposed project combined with other past, present, and reasonably foreseeable future actions is not expected to have a significant impact on surface water resources.

Hydrology and Hydraulics: The proposed project in combination with other past, present, and reasonably foreseeable future actions would potentially significantly impact hydrology and hydraulics. Construction of the proposed project along with the construction of past, present, and reasonably foreseeable future actions could substantially increase the extent of flooding within the Ala Wai watershed such that structures could potentially experience induced flooding. The implementation of mitigation measures such as acquisition, elevation, and floodproofing is anticipated to minimize this potentially significant impact.

Water Quality: The proposed project in combination with other past, present, and reasonably foreseeable future actions would not significantly impact water quality. Although sediment-bound pollutants are known to occur throughout the watershed (particularly in the urbanized

areas), none of the soils that would be exposed by construction are expected to contain excessive levels of contamination. In addition, soils to be exposed would be minor and would be directly linked to the construction of inlet and outlet structures associated with the floodwalls and the Ala Wai Golf Course detention basin. Like the discussion under groundwater quality, construction and maintenance of the proposed project along with the construction of past, present, and reasonably foreseeable future actions could have temporary, localized impacts to water quality if inadvertent spills of petroleum type products associated with use of heavy construction equipment were to occur. However, if construction of other projects identified above and the proposed project occurs at the same time, collectively they are not anticipated to have a significant impact on water quality due to the implementation of BMPs to minimize the risk of inadvertent spills. Long-term, the presence of the Ala Wai Golf Course detention basin could have a minor beneficial impact on water quality as the detention basin would collect water during a storm event and then slowly release it back into the waterway. The slow release of the water back into the waterway would provide some time for suspended sediments binded to contaminants the chance to settle out of the water column.

Sediment Quality: The proposed project in combination with other past, present, and reasonably foreseeable future actions would not significantly impact sediment quality. The construction of the proposed project along with the construction of past, present, and reasonably foreseeable future actions could have temporary, localized impacts as sediment would be disturbed with the construction of inlet and outlet structures associated with the floodwalls and the Ala Wai Golf Course detention basin. Typically, less than 0.02 acres of streambed sediments would have the potential of being disturbed and potentially mobilized with the construction of these structures. Long-term, the Ala Wai Golf Course detention basin would potentially have a minor beneficial effect as water detained within the basin during a storm event would have some time to allow mobilized sediments to settle out within the detention basin. This means water leaving the detention basin could contain less sediment and potentially contaminated sediments, than the water that was entrained in the basins. During maintenance activities, sediment that settles out on the golf course would be collected and disposed of upland. In addition to the proposed project, dredging of the Ala Wai Canal is expected to continue in the future which would aid in removing potentially contaminated sediment from the canal. Therefore, the combination of these actions is expected to not significantly adversely impact sediment quality.

Noise: The proposed project in combination with other past, present, and reasonably foreseeable future actions would have no significant impacts on noise. Cumulatively, construction activities associated with the proposed project and other past, present, and reasonably foreseeable future actions identified in Table 49 would result in temporarily increased noise levels from building and demolition activities, increased presence of construction vehicles, and operation of heavy construction equipment. It is expected that these impacts would be minimized to the extent possible because construction activities would be conducted during standard daytime hours, construction crews would implement BMPs and appropriate measures to avoid and minimize effects of generated noise (e.g., use of equipment mufflers, and orientation of noisy equipment away from residential, park, or gathering areas). See Section 3.3.9, Noise, for a detailed listing of measures that would be implemented to reduce impacts from the proposed project.

Biological Communities: The proposed project in combination with other past, present, and reasonably foreseeable future actions would have long-term, negligible, beneficial and adverse impacts to biological resources, including sensitive species and habitats. Preconstruction

surveys would be required for any construction activities involving tree removal as part of the proposed project, such that no impacts occur to the roosting habitat of the Hawaiian hoary bat.

Conservation Plans: There are no HCPs in place within the proposed action area, therefore, the proposed project would have no impact on HCPs. Since HCPs would not be directly affected by the proposed project, implementation of the proposed project would not contribute to a cumulative effect on the resource. Because of this, the proposed project in combination with other past, present, and reasonably foreseeable future actions would have no cumulative impacts on HCPs.

Agricultural and Forestry Resources: The proposed action area does not occur on areas that are farmed currently, nor areas expected to be converted to farmland in the future. In addition, the proposed project is not located within a designated Conservation District. Therefore, the proposed project would have no impact on agricultural and/or forestry resources. Since agricultural and forestry resources would not be directly affected by the proposed project, implementation of the proposed project would not contribute to a cumulative effect on the resource. Because of this, the proposed project in combination with other past, present, and reasonably foreseeable future actions would have no cumulative impact on HCPs.

Cultural Resources: As stated in Section 3.5.1, the Ala Wai Canal is listed on the Hawaii Register of Historic Places. The proposed project would include the construction of floodwalls along the Ala Wai Canal which would disrupt view plane and setting of the Ala Wai Canal, thereby resulting in a potential adverse effect. Avoidance, minimization, and mitigation measures have been identified in a PA with SHPO dated November 9, 2016 (Appendix L). These measures will be incorporated into the project to offset the adverse effect. Construction of the Ala Bridge Project would result in additional adverse effects to the Ala Wai Canal. Similarly, the Ala Wai Bridge Project will implement mitigation measures, which will be defined in a Memorandum of Agreement (MOA) with SHPO. Therefore, with the consideration of the Ala Wai Bridge Project and the other identified projects in Table 49, the proposed project is not anticipated to contribute to cumulative effects on cultural resources.

Land Use and Planning: The proposed project in conjunction with other past, present, and reasonably foreseeable future actions would have long-term, minor, beneficial impacts on land use and planning. Because the proposed action and other past, present, and reasonably foreseeable future actions would be constructed in a highly developed and modern built environment, less than significant, negligible, adverse impacts on visual resources would be expected. The project would not introduce any incompatible land uses and would be consistent with the urban landscape. Existing land uses would potentially benefit from improved walkways and accessibility due to floodwalls with elevated sidewalks and the Complete Streets Projects.

Hazardous, Toxic, and Radioactive Waste: The proposed project in conjunction with other past, present, and reasonably foreseeable future actions would have a less than significant impact on HTRW. The implementation of BMPs during construction as well as future testing to be conducted on materials that will be excavated to determine the suitability of the soil for re-use or to determine proper disposal would minimize the potential for the release of hazardous materials or waste. Like the discussion under groundwater quality, construction and maintenance of the proposed project along with the construction of past, present, and reasonably foreseeable future actions could have temporary, localized impacts if inadvertent spills of petroleum type products associated with the use of heavy construction equipment were to occur. However, if construction of other project identified above and the proposed project

occurs at the same time, collectively they are not anticipated to have a significant impact on the environment due to the implementation of BMPs to minimize the risk of inadvertent spills.

Recreation: The proposed project in combination with other past, present, and reasonably foreseeable future actions would have less than significant, minor impacts on recreation. As a result of the proposed project and the Complete Streets Projects, the sidewalks on either side of the Ala Wai Canal would be improved as well as the accessibility of the sidewalks. Any impacts to recreational areas, including impacts to aesthetics, would be mitigated through the restoring and replanting of disturbed areas with appropriate landscaping, relocating trees where feasible, and utilizing shielding devices for lighting.

Aesthetics: The proposed project in combination with other past, present, and reasonably foreseeable future actions would have less than significant impacts on aesthetics. If construction of other projects identified above and the proposed project occur at the same time, collectively there would be a short-term minor impact to aesthetics due to the presence of construction equipment and construction activities. Long-term, the combination of the proposed project with other past, present, and reasonably foreseeable future actions would have either minor beneficial or minor adverse impacts to aesthetics depending on perspective. The proposed project would incorporate mitigation measures such as lava rock façade to blend in the proposed floodwalls with the character of the surrounding area. In addition, the proposed floodwalls along the Ala Wai Canal include an elevated walking path which in combination with Complete Streets Projects, would improve sidewalks as well as accessibility of the sidewalks. The above could be seen as a minor long-term beneficial effect to the aesthetics of the area. Conversely, the construction of floodwalls along the Ala Wai Canal and in other areas would contribute to the already urbanized aesthetic of the area. The height of the floodwalls would also impede views of the Ala Wai Canal to vehicular traffic, bicyclists, and pedestrians not using the elevated walking path along the canal. Lastly, the construction of the floodwalls along the Ala Wai Canal would require the removal of trees along the canal and replanting of trees within 15 feet of the floodwalls would not be allowed due to maintenance requirements. The above could be seen as a long-term adverse effect to the aesthetics of the area.

Public Health and Safety: The proposed project in combination with other past, present, and reasonably foreseeable is not expected to substantially increase health and safety risks to residents and visitors. If construction of other projects identified above and the proposed project occur at the same time, collectively there would potentially be short-term minor adverse impacts to public health and safety due to the presence of construction vehicles and construction activities. However, the implementation of BMPs such as fencing around construction areas, slow speeds for construction vehicles, etc. the potential temporary adverse impacts would be minimized. Long-term, a beneficial cumulative impact is anticipated since the purpose of the project is flood risk management which would reduce flood risk and damage to the area.

Public Service and Utilities: The proposed project in combination with other past, present, and reasonably foreseeable future actions would have short-term, minor effects and long-term minor effects on public services and utilities. Temporary, minor, cumulative effects could be expected because of construction activities which may be within the vicinity of public service facilities, therefore, delaying access to these facilities. It is important to note, however, that access to public service facilities would not be completely blocked off; there may be a delay to accessing areas if construction vehicles need to move out of the way to allow access. Long-term, the operation of the project would prevent easy access to some areas due to road closure structures that would need to be put in place prior to a storm event arriving, during the storm event, and for a relatively short period of time after the storm event has passed through.

Although this would be an adverse effect, it is anticipated to be minor since the project would minimize flooding in areas thereby allowing continued access that may have been limited under the future without project condition. Clean up following a storm event would likely need to occur, but it would be no different than what currently occurs under the future without project condition following a storm event. Therefore, the long-term effect could be beneficial by allowing continued access to areas that may have been in accessible due to flooding under the future without project condition. The long-term effect would also be a less than significant adverse impact due to road closure structures needing to be in place prior to a storm event arriving, which would block of access to areas that were accessible under the future without project condition.

Transportation and Traffic: The proposed project in combination with other past, present, and reasonably foreseeable future actions would have short-term, minor effects and long-term, minor, effects on transportation and traffic. Temporary, minor, cumulative effects could be expected because of construction related road or intersection closures from the proposed project in combination with other past, present, and reasonably foreseeable future actions identified in Table 49. However, signage as well as potential detours would be established where necessary to minimize inconvenience and prevent excessively delayed traffic. Temporary, minor, cumulative effects could be expected long-term because of closing road closure structures prior to a projected storm event and temporarily after a projected storm event. The closing of road closure structures when combined with other past, present, and reasonably foreseeable future actions identified in Table 49 could result in increased detours and congested roadways during storm events for residents and tourists as well as for construction workers and construction vehicles working in areas where road closure structures are located.

Socioeconomic/Environmental Justice: No significant impacts are expected because of the proposed project in combination with other past, present, and reasonably foreseeable future actions listed in Table 49. Cumulative effects are anticipated to be temporary and minor during construction of the proposed project. Cumulative effects over the long term of the project are anticipated to be minor.

3.8 Relationship Between Short-term Uses of the Environment and Maintenance and Enhancement of Long-term Productivity

The analysis of short-term uses versus long-term productivity considers the relationship between local short-term uses of man's environment and the maintenance and enhancement of long-term productivity. This should include a discussion on the extent to which the alternatives involve tradeoffs among short-term and long-term gains and losses, as well as whether future options are foreclosed, whether the range of beneficial uses of the environment are narrowed, and whether the alternatives poses long-term risks to health and safety.

As described throughout the documents, the proposed alternatives would involve construction and operation of measures that would function to reduce the risk of flooding throughout the Ala Wai watershed. Implementation of these measures would result in potential short-term, adverse impacts to noise, cultural resources, recreation, and aesthetics. Given the efforts to avoid, minimize, and mitigate potential environmental impacts, the project is not expected to substantially narrow the range of beneficial uses of the environment or foreclose future options. Overall, the proposed alternatives are designed to minimize flood-related risk, thereby reducing health and safety hazards, as well as protecting housing units, commercial structures, and public facilities from flooding. By decreasing flood risk, the proposed alternatives would reduce the potential for incurring costs associated with clean-up, debris removal, and building and

infrastructure repair as a result of flood events, thus maintaining productivity and increasing the potential for long-term growth opportunities throughout the watershed. Given the extent of area and the affected population protected from flood hazards relative to the anticipated environmental impacts, the project-related efforts to enhance long-term productivity are expected to outweigh the short-term uses of the environment.

3.9 Irreversible or Irretrievable Commitments of Resources

An irreversible or irretrievable commitment of resources refers to impacts on or losses to resources that cannot be reversed or recovered, even after an activity has ended and facilities have been decommissioned. A commitment of resources is related to use or destruction of nonrenewable resources, and effects that such a loss will have on future generations. For example, if prime farmland is developed there would be a permanent loss of agricultural productivity. The proposed project would involve the irreversible and irretrievable commitment of material resources and energy, land resources, and human resources. The impacts on these resources would be permanent.

Material Resources. Material resources irretrievably used for the proposed project could include steel, concrete, lave rock, and possibly other materials for construction. Such materials are not expected to be in short supply and would not be expected to limit other unrelated construction activities. The irretrievable use of material resources would not be considered significant.

Energy Resources. Energy resources used for the proposed project would be irretrievably lost. These would include petroleum-based products (e.g., gasoline and diesel) and electricity. During construction, gasoline and diesel fuel would be used for the operation of construction vehicles. Consumption of these energy resources would not place a significant demand on their availability in the region. Therefore, no significant impacts would be expected.

Human Resources. The use of human resources for construction is considered an irretrievable loss only in that it would preclude such personnel from engaging in other work activities.

Chapter 4: Plan Comparison and Selection

4.1 Plan Comparison

A summary of the comparison of the final array of alternatives is presented below in Table 50. A summary of comparison with respect to the four accounts, evaluation criteria, contribution to the planning objectives, and risk and uncertainty are provided in the following sections.

Table 50: Summary of Comparison of the Final Array of Alternatives

Consideration	Alt. 0. No Action	Alt. 1. Storage Plan	Alt. 2B. Conveyance Plan	Alt. 5. Hybrid Plan	Alt. 6. Nonstructural Plan
1. Account Analysis					
A. National Economic Development (NED)					
(1) Average Annual Net Benefits	$0	$17,743,000	$23,195,000	$33,104,000	$14,023,000
(2) BCR	0	3.0	2.1	2.7	1.8
(3) Rank	5th	4th	2nd	1st	3rd
B. Regional Economic Development (RED)					
(1) Employment*	0 jobs	2,197 jobs	5,562 jobs	8,141 jobs	6,279 jobs
(2) Labor Income	$0	$161,392,000	$408,582,000	$608,967,000	$447,000,000
(3) Rank	5th	4th	2nd	1st	3rd
C. Other Social Effects					
(1) Life Safety	0 decrease in expected annual life loss	0.09 increase in expected annual life loss	0.18 increase in expected annual life loss	0.003 reduction in expected annual life loss	0 reduction in expected annual life loss
(2) Social Vulnerability	No additional impacts to socially vulnerable communities	Medium benefit to socially vulnerably communities	Largest increase in risk to socially vulnerable communities	Largest benefit to socially vulnerable communities	No significant benefit anticipated for socially vulnerable communities
(3) Rank	4th	2nd	5th	1st	3rd
D. Environmental Quality					
(1) Environmental Impacts	No additional impact to environmental resources	Minimally impactful to environmental resources	Most impactful to environmental resources	Minimally impactful to environmental resources	Least impactful to environmental resources
(2) Rank	2nd	3rd (tie)	4th	3rd (tie)	1st
2. Alternative Evaluation					
A. Criteria					
(1) Efficiency	No net economic benefits. Rank = 5th	$17,743,000 in net benefits. Rank = 3rd	$23,195,000 in net benefits. Rank = 2nd	$33,104,000 in net benefits. Rank = 1st	$14,023,000 in net benefits. Rank = 4th
(2) Effectiveness (Damage)	No damages reduced. Rank = 5th	$26,835,000 in damages reduced. Rank = 4th	$43,464,000 in damages reduced. Rank = 2nd	$52,303,000 in damages reduced. Rank = 1st	$32,367,000 in damages reduced. Rank = 3rd

(3) Effectiveness (Life Safety)	No reduction in life safety risk. Rank = 2nd (tie)	0.180 increase in expected annual life safety risk. Rank = 4th	0.092 increase in expected annual life safety risk. Rank = 3rd	0.003 reduction in expected annual life safety risk. Rank = 1st	No significant change in life safety risk. Rank = 2nd (tie)
(4) Acceptability	Meets acceptability criteria. Rank=1st (tie).	Meets acceptability criteria. Rank=1st (tie).	Meets acceptability criteria. Rank=1st (tie).	Meets acceptability criteria. Rank=1st (tie).	Meets acceptability criteria. Rank=1st (tie).
(5) Completeness	Meets completeness criteria. Rank=1st (tie).	Meets completeness criteria. Rank=1st (tie).	Meets completeness criteria. Rank=1st (tie).	Meets completeness criteria. Rank=1st (tie).	Meets completeness criteria. Rank=1st (tie).
(6) Environmental Effects	No effect on environmental resources. Rank = 1st.	No significant effects on environmental resources. Rank =2nd (tie).	No significant effects on environmental resources. Rank =2nd (tie).	No significant effects on environmental resources. Rank =2nd (tie).	No significant effects on environmental resources. Rank =2nd (tie).
(7) Rank	5th	4th	2nd	1st	3rd
B. *Contribution to Objectives*					
(1) Life Safety	No benefits to life safety. Rank = 2nd (tie).	Highest induced life safety risk. Rank = 4th.	Induced life safety risk. Rank = 3rd.	Largest reduction in life safety risk. Rank = 1st.	No benefits to life safety risk. Rank = 2nd (tie).
(2) Economic Damages	No reduction in economic damages. Rank = 5th.	$26,835,000 in damages reduced. Rank = 4th	$43,464,000 in damages reduced. Rank = 2nd	$52,303,000 in damages reduced. Rank = 1st	$32,367,000 in damages reduced. Rank = 3rd
(3) Reduce impacts to commerce and tourism	No reduction in disruptions to commerce and tourism. Rank = 5th.	Minor effects on Waikiki and Ala Moana. Positive effect on Manoa. Rank = 3rd.	Positive impact to Waikiki and areas along Manoa. Negative effect to Ala Moana. Rank = 2nd.	Greatest positive impact (i.e., reduced risk) in all target reaches. Rank = 1st.	Would benefit target reaches; participation may impact benefits. Rank = 4th.
(4) Rank	5th	4th	2nd	1st	3rd
C. Risk and Uncertainty					
(1) Residual Risk	No change in flood risk throughout the watershed. Greatest residual risk. Rank=5th.	Fourth largest reduction in residual risk. Rank = 4th.	Second largest reduction in residual risk. Rank = 2nd.	Largest reduction in residual risk. Rank = 1st.	Third largest reduction in residual risk. Rank = 3rd.

(2) Uncertainty	Relies completely on non-federal action to reduce flood risk. Rank = 3rd.	Mitigation requirements are currently unknown. Rank = 1st (tie).	Mitigation requirements are currently unknown. Rank = 1st (tie).	Mitigation requirements are currently unknown. Rank = 1st (tie).	Participation rates could affect benefits. Rank = 2nd.
(3) Rank	5th	4th	2nd	1st	3rd

*Jobs are presented in full-time equivalence (FTE).

System of Accounts. Alternative 5 has the greatest net economic benefits ($33,104,000). Alternative 1 has the highest BCR (3.0). Alternative 5 is the alternative that has the highest RED, NED, and OSE benefits, and has minimal impacts to the EQ account.

Alternative Evaluation. Alternative 5 was ranked 1st in terms of evaluation based on the planning criteria, being ranked 1st or tying for 1st based on efficiency (i.e., largest expected net economic benefits), effectiveness (i.e., maximally reduces economic damages and life safety risk), completeness, and acceptability. Alternative 5 is also not expected to have significant environmental effects. Alternative 5 also maximally meets all three planning objectives of reducing economic damages, impacts to commerce and tourism, and life safety risk. Finally, Alternative 5 is characterized by the least residual risk and has similar uncertainty related to mitigation for induced flooding and interior drainage as compared to Alternatives 1 and 2B.

4.2 Identification of the NED Plan

Federal policy requires identification of the plan that reasonably maximizes net NED benefits (i.e., the NED plan); the NED plan must be recommended for implementation unless there are overriding reasons for recommending another plan. Alternative 5 was identified as the NED plan with the highest net NED benefits of $33,104,000.

4.3 Plan Selection

Alternative 5 was selected as the Tentatively Selected Plan (TSP) given that it is both the NED Plan and the Comprehensive Benefits Plan; Alternative 5 reasonably maximizes net NED benefits and benefits across all Four Accounts and is the most competitive alternative within the Final Array of Alternatives.

Chapter 5: The Tentatively Selected Plan

5.1 Plan Accomplishments

Alternative 5 (Hybrid Plan) is the TSP.

The TSP maximizes benefits within the NED, RED, and OSE accounts, having the greatest net economic benefits, regional economic benefits (i.e., labor income and jobs supported), maximizing reductions in life safety risk, and maximizing benefits to socially vulnerable communities and populations. The TSP is the most equitable in terms of flood risk reduction by ensuring socially vulnerable communities experiencing recurring and frequent flooding receive comparable flood risk reduction opportunities as more affluent communities in the watershed.

The TSP will have only minor environmental impacts and is an acceptable plan from an environmental standpoint. Specifically, the recommended plan will not have significant impacts on the environment under the NEPA and will have no effect on federally listed species or designated critical habitat under the ESA. The TSP can be implemented in compliance with all applicable environmental laws and regulations. The TSP will constitute an undertaking under Section 106 of the National Historic Preservation Act (NHPA) and has a potential to affect historic properties listed on, or determined eligible for, the National Register of Historic Places under 36 C.F.R. § 800.3. All compliance and mitigation requirements under Section 106 will be satisfied prior to project implementation.

5.2 Plan Components

Alternative 5 (Hybrid Plan) includes the Makiki District Park Detention Basin, Manoa Valley District Park Detention Basin, Woodlawn Drive Floodwall, and the Koali Road Floodwall. Figure 26 provides a conceptual diagram of Alternative 5.

Ala Wai Golf Course Detention Basin– At the Ala Wai Golf Course, adjacent to the Manoa-Palolo Canal and the Ala Wai Canal, an earthen levee approximately 6 ft in height would be constructed around the perimeter of Ala Wai Golf Course to create a detention basin (i.e., Ala Wai Golf Course Detention Basin). The total length of the earthen levee would be approximately 5,640ft in length and would extend along the perimeter of the Ala Wai Golf Course along the Manoa-Palolo and Ala Wai canals. Near the vicinity of the Kapahulu Avenue and Ala Wai Boulevard intersection, the levee would join with the Ala Wai Canal Floodwall on the left descending bank of Ala Wai Canal. The existing drainage ditch that runs along the north side of the golf course (parallel to Date Street) would be riprapped and used as an inlet for stormwater to overflow into the Ala Wai Golf Course Detention Basin. Three concrete drainage structures with flap gates would be constructed along the southwest side of the Ala Wai Golf Course to allow collected stormwater to slowly drain into Ala Wai Canal. The Ala Wai Golf Course Detention Basin would reduce the risk of flooding within the lower watershed.

Manoa Valley District Park Detention Basin– At Manoa Valley District Park, in Manoa Valley, a detention basin (i.e., Manoa Valley District Park Detention Basin) would be constructed to temporarily store stormwater. The detention basin would be constructed by excavating down approximately 6 to 8 ft and constructing a 6-foot-high around the perimeter of the park (~1,580 ft in length). The Manoa Valley District Park Detention Basin would have a storage volume of approximately 54 acre-feet. The purpose of the Manoa Valley District Park Detention Basin is to reduce the risk of flooding to residential structures downstream of the park.

Makiki District Park Detention Basin – At Makiki District Park, in Makiki Valley, a detention basin (i.e., Makiki District Park Detention Basin) would be constructed to temporarily store stormwater runoff. The detention basin would be constructed by excavating down approximately 6 to 10 ft and constructing a 6-foot-high floodwall with earthen slopes around the perimeter of the park (~1,200 ft in length). The Makiki District Park Detention Basin would have a storage volume of approximately 22 acre-feet. A floodwall extending 6 ft above ground level would be constructed along the right descending bank of the Kanaha Ditch (i.e., Kanaha Floodwall). The floodwall would be approximately 2,200 ft long, with five road closure structures. The Makiki District Park Detention Basin and Kanaha Floodwall function as a system, with the floodwall helping to move water efficiently and effectively from the Kanaha Ditch into the Makiki District Detention Basin, reducing the risk of flooding for adjacent and downstream communities.

Ala Wai Canal Floodwall & Kaimuki High School Floodwall– At the Manoa-Palolo Canal and Ala Wai Canal, a floodwall extending 6 ft above ground (i.e., Ala Wai Canal Floodwall) would be constructed. The floodwall would be approximately 24,140 ft long. Fourteen existing stormwater sewers inletting into the Ala Wai Canal would be modified to include a flap gates. Twelve road closure structures would be constructed. The purpose of the Ala Wai Canal Floodwall would be to reduce the risk of flooding within the McCully-Moiliili neighborhood, Diamond Head neighborhood, and Waikiki. At Kaimuki High School, adjacent to the Manoa-Palolo Canal, a floodwall extending 6 ft above ground (i.e., Kaimuki High School Floodwall) would be constructed along the left descending bank of Manoa Manoa-Palolo Canal. The floodwall alignment is different from the alignment in Alternatives 1 and 2B. Under Alternative 5, the Kaimuki High School Floodwall would be approximately 3,260 ft long, cutting between the athletic fields and joining the Ala Wai Canal Floodwall near Date Street. The Kaimuki High School Floodwall would reduce flood risk within communities east/southeast of Kaimuki High School. The Ala Wai Canal and Kaimuki High School Floodwalls would function as a system.

Woodlawn Drive Floodwall & Koali Road Floodwall– Also within Manoa Valley, a floodwall extending 6 ft above ground level (i.e., Woodlawn Drive Floodwall) would be constructed along the right descending bank of Manoa Stream. The floodwall would be approximately 1,625 ft in length. A single road closure structure at Woodlawn Drive would be constructed. The Woodlawn Drive Floodwall would reduce the risk of flooding to the University of Hawaii and downstream residential structures due to overtopping at Woodlawn Drive Bridge. At Koali Road, near the convergence of Manoa and Palolo streams, a floodwall extending 6 ft above ground (i.e., Koali Road floodwall) would be constructed along the left descending bank of Manoa Stream and the right descending bank of Palolo Stream. The floodwall would be approximately 2,485 ft in length. Two box culverts would be constructed to provide interior drainage of stormwater flows from the residential neighborhood behind the Koali Road floodwall. Two road closure structures would be constructed. The purpose of the Koali Road Floodwall is to reduce risk to adjacent residential structures, including induced damages caused by the Woodlawn Drive Floodwall. Thus, the Woodlawn Drive Floodwall and Koali Road Floodwall function as a system.

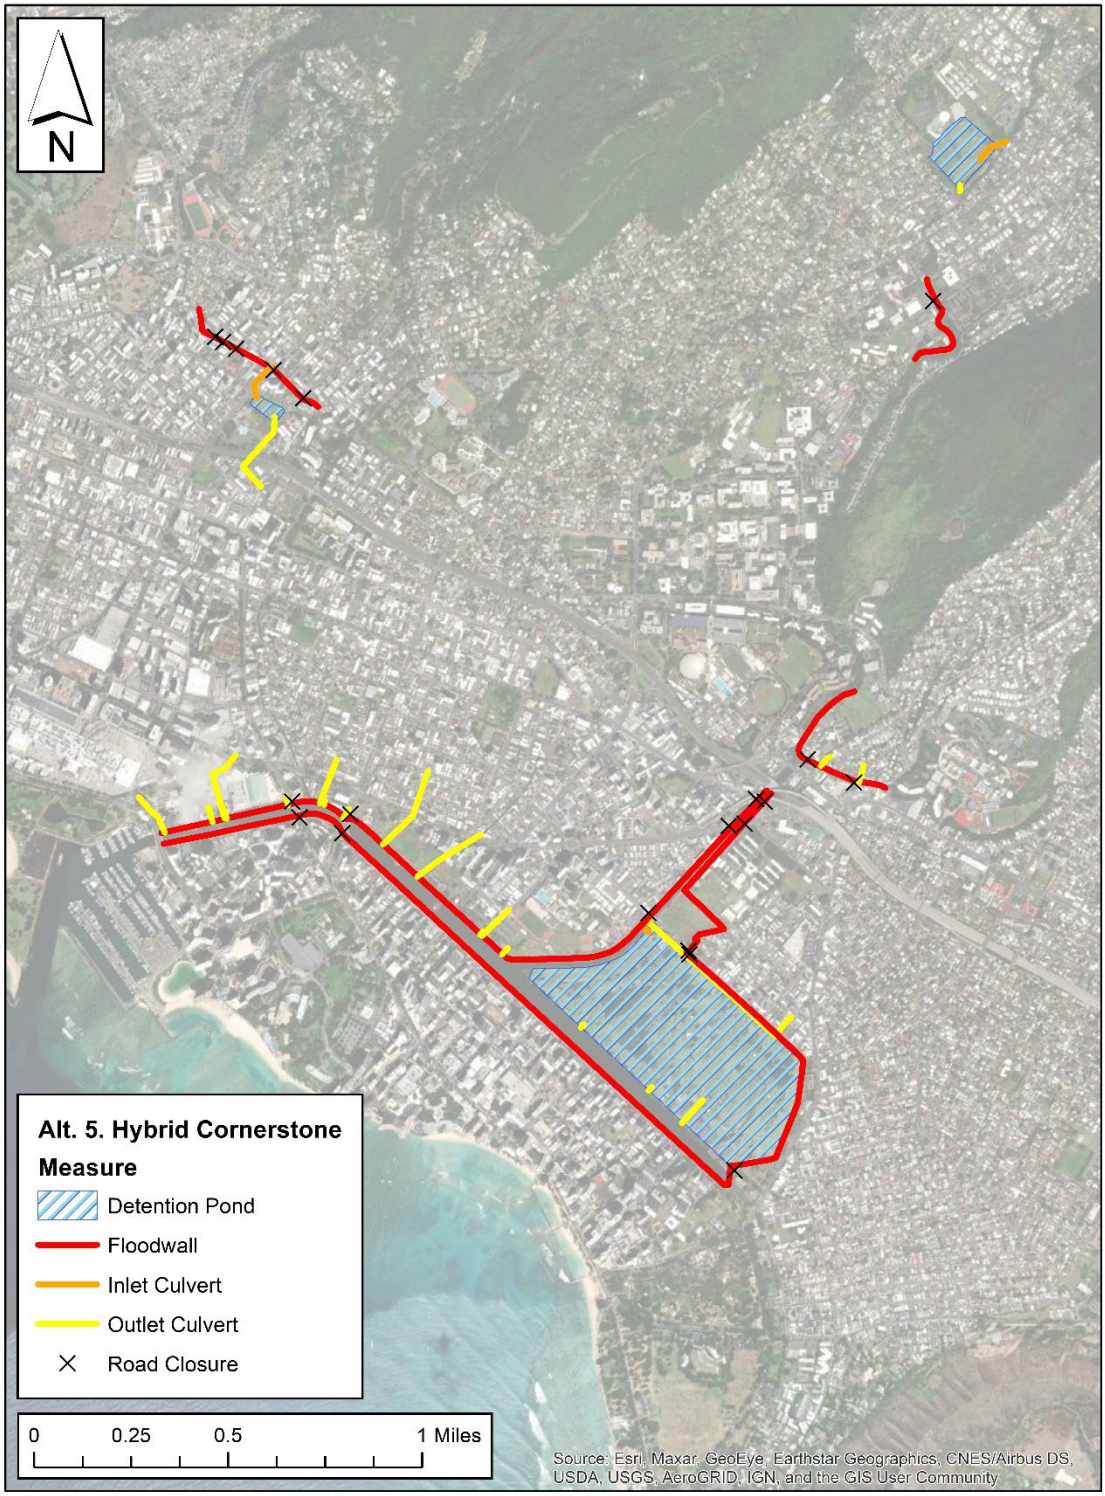

Figure 26: Conceptual Diagram of Alternative 5.

Incremental Justification

The study team conducted an incremental justification analysis for measures included in Alternative 5—the NED and comprehensive benefits plan. For the purposes of this analysis, the study team considered the following as separable elements:

Table 51: Incremental Justification Assessment

Element/System	Analysis & Results	Determination
Makiki District Park Detention Basin and Kanaha Floodwall	Additional H&H and economic analysis indicated that the Makiki District Park Detention and Kanaha Floodwall are not separably economically justified (i.e., benefits do not outweigh the costs), do not substantially reduce life safety risk, and would not benefit the most socially vulnerable communities.	Remove from Alternative 5.
Manoa District Park Detention Basin	Additional H&H and economic analysis indicated that the Manoa District Park Detention Basin is not separably economically justified, does not substantially reduce life safety risk, and would not benefit the most socially vulnerable communities.	Remove from Alternative 5
Woodlawn Drive Floodwall and Koali Road Floodwall	H&H and economic results were compared with and without the Woodlawn Drive and Koali Road Floodwall system. These results indicated that these measures are economically justified (i.e., benefits outweigh the costs) and would benefit the most socially vulnerable communities.	Retain in Alternative 5
Ala Wai Golf Course Detention Basin	Comparison of model runs with and without the Ala Wai Golf Course Detention Basin indicate that it is economically justified (i.e., benefits outweigh the cost) and that it helps reduce induced risk resulting from the other project features.	Retain in Alternative 5
Ala Wai Canal Floodwall and Kaimuki High School Floodwall	Comparison of model runs with and without the Ala Wai Canal and Kaimuki High School Floodwalls indicate these measures are separably justified (i.e., benefits outweigh the costs) and that it helps reduce risks to socially vulnerable populations.	Retain in Alternative 5

Alternative 5.1–- Modified Tentatively Selected Plan (TSP). A summary and associated map of the features included in the tentatively selected plan after completion of the incremental analysis efforts is provided below; this modification of Alternative 5 is being called Alternative 5.1 (Figure 27).

From Alternative 5, the modified TSP includes the Ala Wai Golf Course Detention Basin, Ala Wai Canal Floodwall, Kaimuki High School Floodwall, Woodlawn Drive Floodwall, and the Koali

Road Floodwall and excludes the Manoa Valley District Park Detention Basin and the Makiki District Park Detention Basin.

Figure 27: Conceptual Diagram of Alternative 5.1.

Optimization

The study team optimized Alternative 5.1 with a two-fold goal. First, the study team assessed whether structural features within the TSP could be modified to reduce residual risk while also capturing more project benefits and, second, the study team wanted to minimize the potential for induced flooding and induced damages to occur from implementation of the TSP.

Table 52 summarizes the progression of Alternative 5 as it evolved through the plan formulation process. These changes were informed by extensive modeling and detailed evaluations to determine if the changes were effective in meeting the aforementioned goals.

The study team also analyzed the possibility of including physical nonstructural measures into Alternative 5, based on previous analysis which had identified reaches where nonstructural measures would likely be economically justified as standalone measures and within reaches where the study team believe residual flood risk could be reduced further through the application of nonstructural measures. Figure 28 provides a conceptual diagram of the reaches where nonstructural measures were considered for inclusion in the TSP; only reaches AW2R, AW2L, and AW9R were considered.

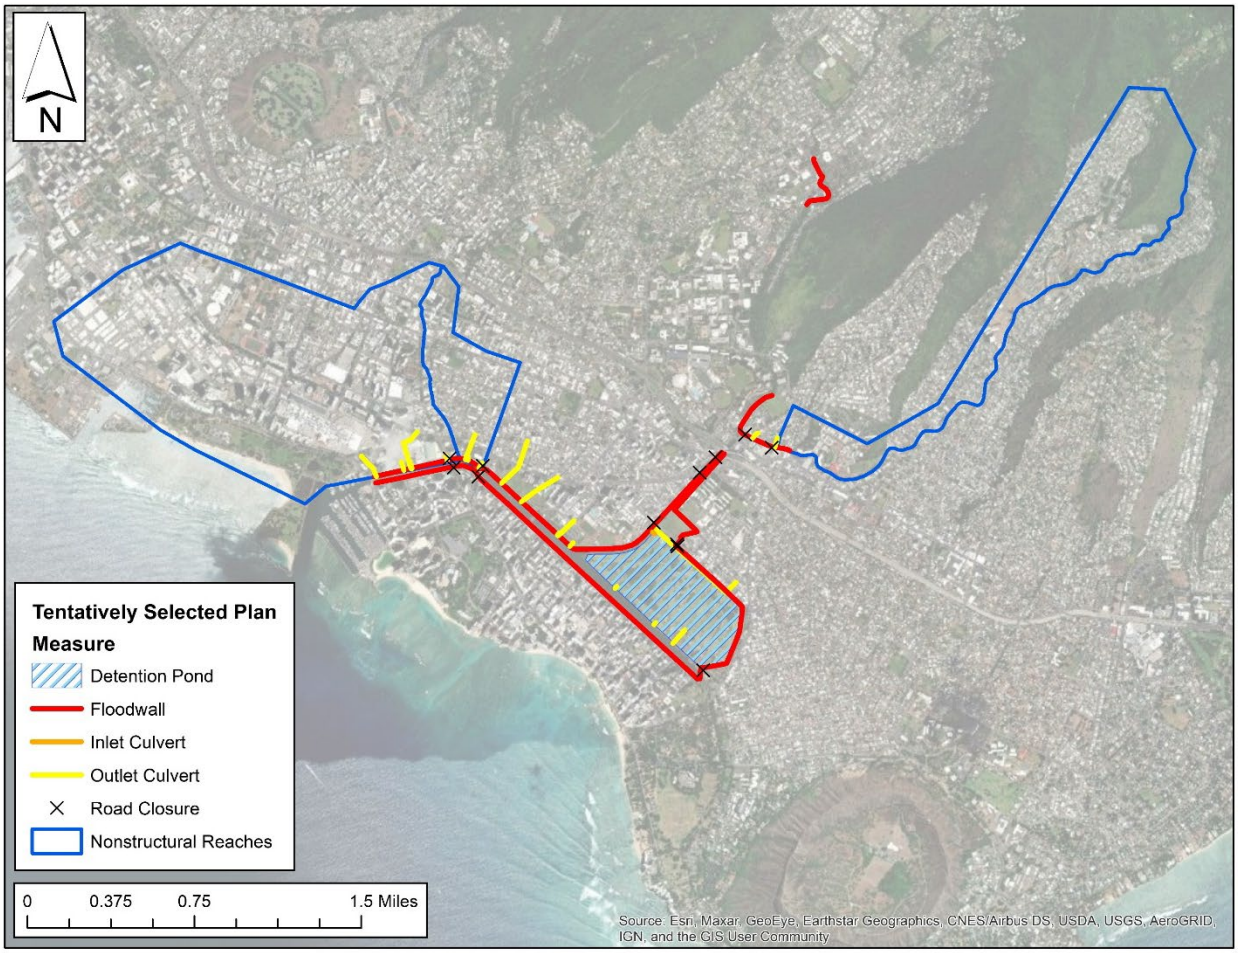

Figure 28: Conceptual Diagram of Potential Nonstructural Measures for Alternative 5.

Nonstructural measures were screened from inclusion in the TSP for the following reasons:

- A high-level economic analysis was conducted on Alternative 5 to assess the viability of incorporating nonstructural measures in conjunction with structural measures. This analysis concluded that is unlikely that incorporating structural measures in conjunction with nonstructural measures within the target reaches would result in a substantial increase in benefits.
- The structure groupings which were most likely to realize the highest benefits, via the application of nonstructural measures, were already receiving benefits from key structural measures in Alternative 5.
- Neither the effectiveness nor the efficiency of the Alternative 5 would be enhanced through the inclusion of nonstructural measures.

Table 52: Summary of Changes to Alternative 5 (TSP).

Alternative	Measures Added/Modifications	Measures Removed
Alternative 5.1 (Incremental Analysis)	None.	Makiki District Park Detention and the Kanaha Floodwall were removed because this measure was not justified when evaluated as a separable element. Manoa Valley District Park Detention was removed because this measure was not justified when evaluated as a separable element.

Alternative	Measures Added/Modifications	Measures Removed
Alternative 5.2 (Optimization)	Makiki Floodwalls were added to address induced flooding concerns in Lower Makiki. A ringwall around the club house at the Ala Wai Golf Course was added to address flooding concerns at the club house. Berm and floodwall alignments were adjusted on the southeastern portion of the Ala Wai Golf Course Detention to improve the performance of the system. The alignment of floodwalls near Kaimuki High School was adjusted to improve the performance of the system. An elevated walking path was added to the Ala Wai Canal Floodwalls to mitigate for negative viewshed impacts.	
Alternative 5.3 (Optimization)	Floodwall alignment adjusted at the Ala Wai Community Park to improve channel conveyance. Floodwall alignment on the Ala Wai Canal, near the golf course, was adjusted to increase channel conveyance. Many segments of the berm around the Ala Wai Golf Course were raised from 6 feet to 9 feet to increase total storage volume of the Ala Wai Golf Course detention feature.	Makiki Floodwalls were removed because additional analysis concluded that they were not effective in reducing potential induced damages. Ringwall at the Ala Wai Golf Course removed to increase the storage area of the Ala Wai Golf Course detention. Wet floodproofing of the clubhouse will likely be needed.

Figure 29 visually displays the changes of Alternative 5.2, which led to the TSP maturing into Alternative 5.3. All substantial changes to Alternative 5.2 are displayed in red on the figure.

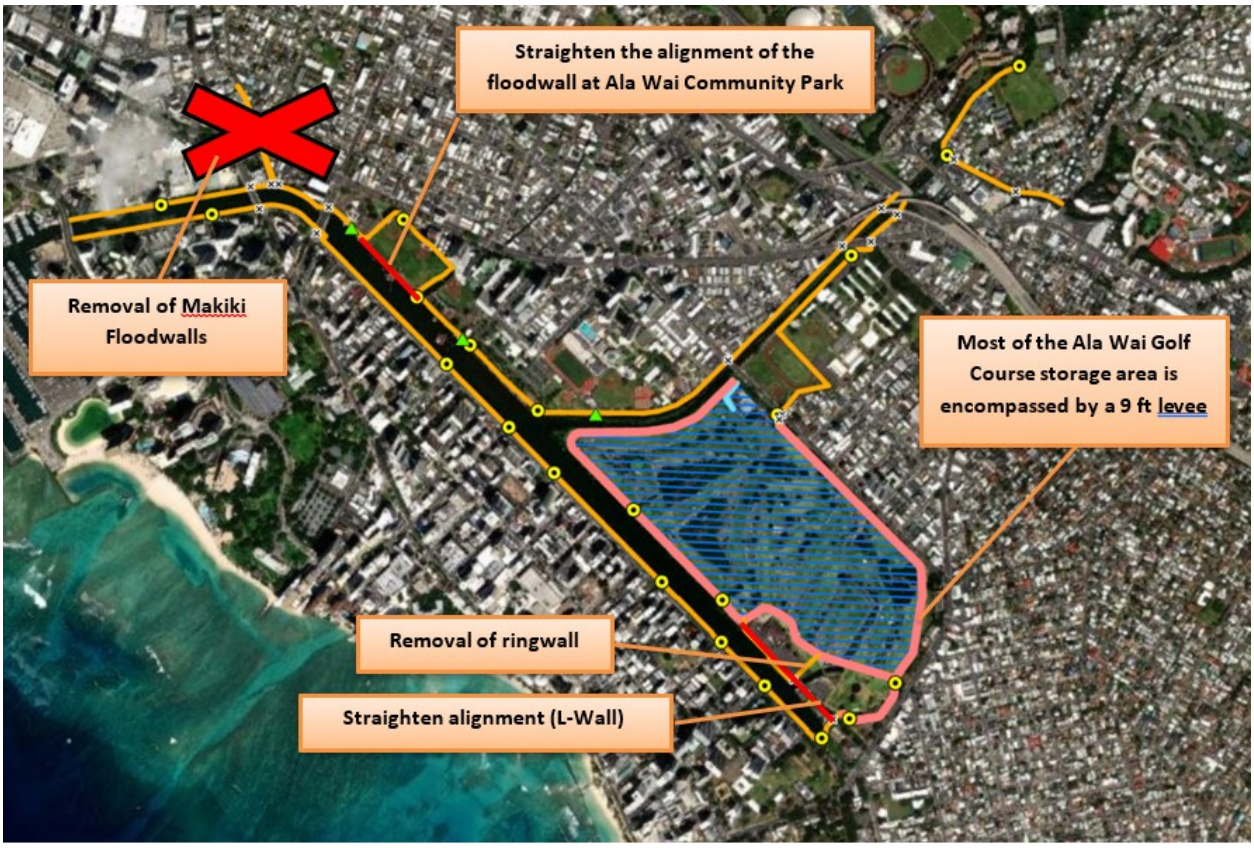

Figure 29: Conceptual Diagram of Changes to Alternative 5.2.

Alternative 5.3 is a considerable improvement from Alternative 5 in that the benefits it captures have been optimized; additionally, induced damages have been reduced, to the extent possible, through extensive adjustments to the structural measures contained in the alternative. Figure 30 displays a conceptual diagram of Alternative 5.3 and its optimized measures. Alternative 5.3 is the optimized version of Alternative 5 that is being recommended in this report.

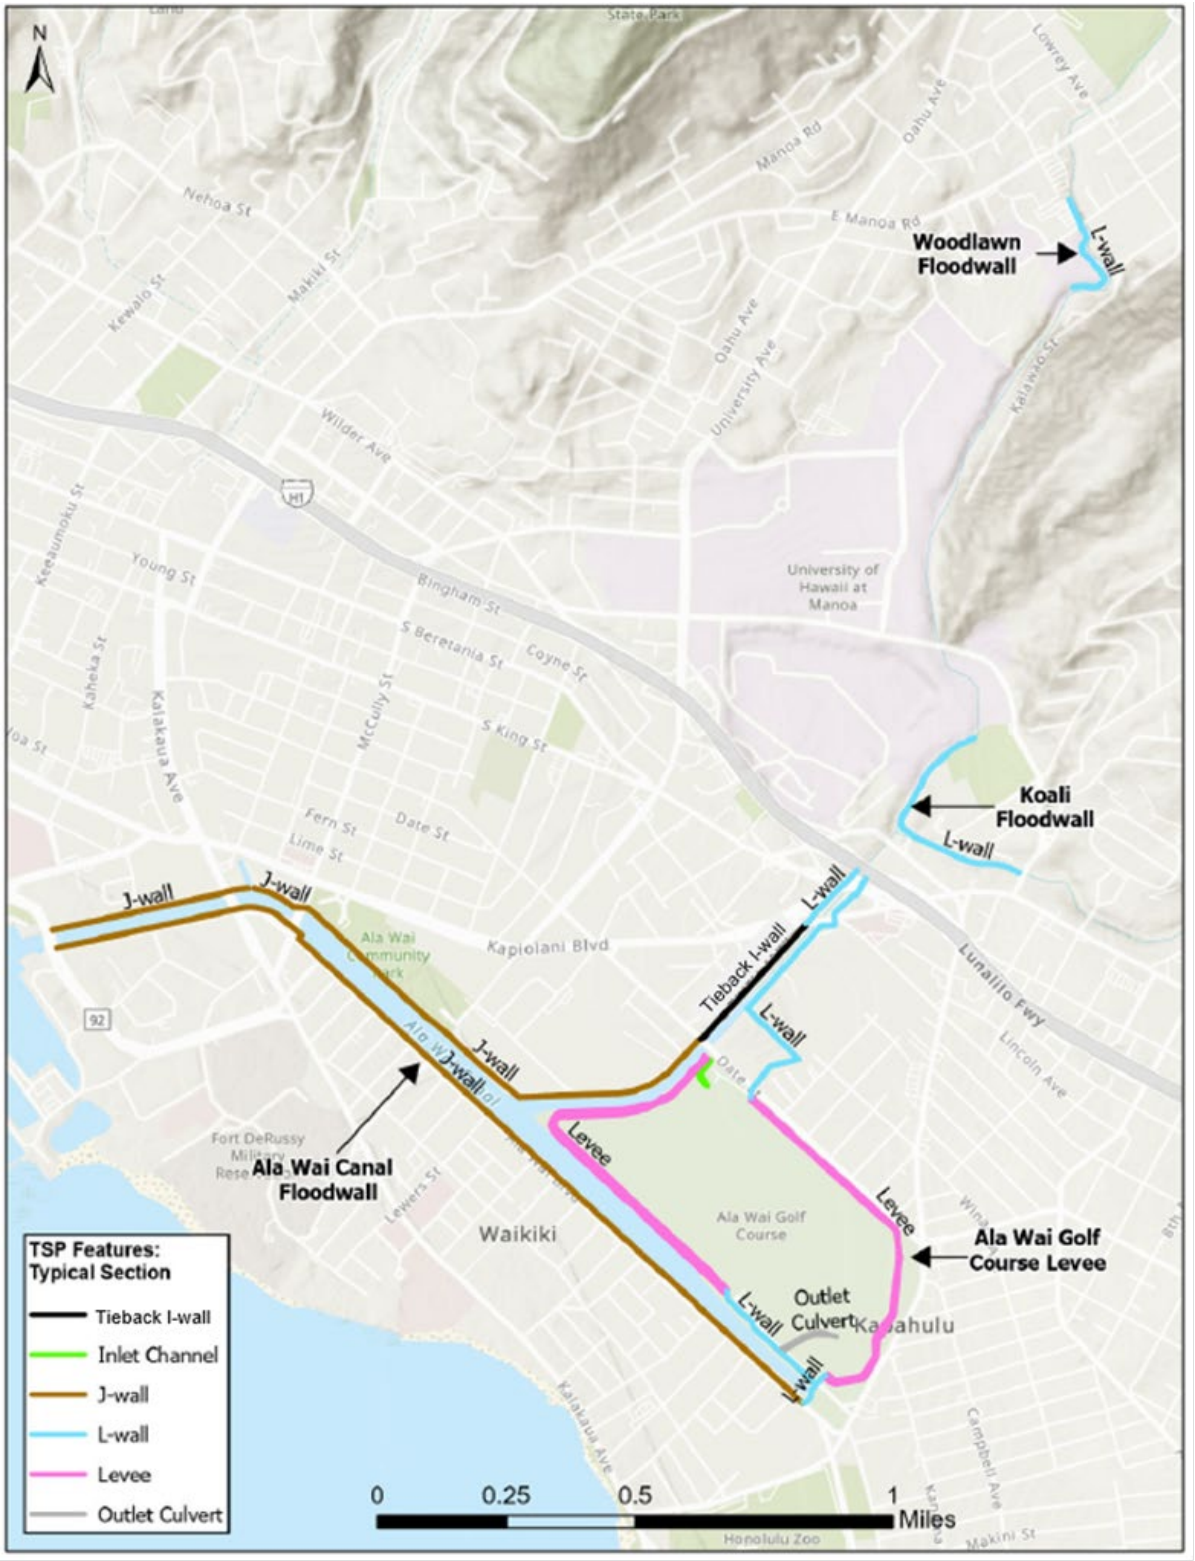

Figure 30: Conceptual Diagram of Alternative 5.3.

Mitigation

Formulation of Mitigation Measures

Efforts to address potential induced flooding were undertaken in accordance with Engineer Regulation 1105-2-100, Planning Guidance Notebook, dated USACE policy and guidance, which directs development of mitigation when economically justified, if there are overriding reasons of safety, economic, or social concerns, and/or if a determination of a real estate taking has been made.

Structures with less than 0.5 feet of induced flooding were assumed to not require mitigation for induced flooding because data inputs and modeling do not allow for differentiation of outcomes at or below 0.5 feet of flood depth. This assumption is based on multiple factors including data inputs and model uncertainty. Uncertainties are accounted for in the HEC-RAS model and in the HEC-FDA portion of the analysis including accuracy of terrain data (described in Appendix B). The primary sources of uncertainty present in the calculation of economic damages include storm water discharge, water surface elevations, levee performance, structure elevations including first floor elevations, structure and structure content values, and depth-damage relationships. Further, the method for establishing induced flooding requires modeling water surface elevation and structures over a grid. The grid methodology can sometimes show a small decimal water surface elevation change in a grid where there is no true water surface elevation change (referred to as model noise). The model cannot establish induced flooding below 0.5 feet due to this uncertainty combined with uncertainty about first floor elevations (described in Appendix C).

This assumption is additionally based on the Federal Emergency Management Agency (FEMA)/USACE Joint Actions on Planning for Flood Risk Management Projects memorandum, dated 29 June 2012. This memorandum helps define areas requiring revisions to flood insurance rate maps under National Flood Insurance Program (NFIP) regulations (44 C.F.R. 65.12) and mitigation associated with induced flooding following implementation of a USACE flood risk management project. Specifically, areas subject to 44 C.F.R. 65.12 and mitigation for induced flooding are those where: '…a logical transition can be shown between the revised flood elevations, flood plain boundaries, and floodways and those developed previously for areas not affected by the revision. Unless it is demonstrated that it would not be appropriate, the revised and unrevised base flood elevations must match within one-half foot where such transitions occur.' This assumption will be reevaluated during PED following any updates to the models or underlying data. Reevaluation will be reflective of model and site-specific uncertainties, which may be greater or less than the 0.5 feet of induced flooding described above.

Potential mitigation actions were developed for structures with greater than 0.5 feet of induced flooding for the 5% and 1% AEP events to provide a range of potential mitigation options in the face of uncertainty in potential mitigation requirements. Real estate analysis evaluates parcels while economic analysis uses a structure inventory to identify individual structures. Costs associated with mitigation for structures is based on total structures regardless of whether multiple structures are located on single real estate parcels.

With Alternative 5.3 in place, water surface elevation would be induced slightly for certain events and reaches. Induced flooding generally occurs in areas that are flooding under the FWOP condition, and the additional water surface induced by the project is minimal for frequent events and larger for the least frequent events. The most frequent event at which a structure

with no FWOP flooding becomes flooded is the 10% AEP event. There are 21 structures (out of nearly 6,000 in the floodplain) that have induced flooding at the 1% AEP flood event that do not already experience FWOP flooding. Structures with expected induced flooding will be evaluated on an individual basis to determine annualized impact over the full stage-frequency curve rather than just a single event. There may be some instances where structures see induced flooding at one event, but the annualized impact is negligible, or even beneficial. Conversely, some of these structures may see induced flooding across multiple events and require a different kind of mitigation. The uncertainty in the cost of these activities is captured in the range of costs due to mitigation.

Potential Mitigation Measures

Pump Station: Mitigation measures related to induced flooding include potentially adding permanent pump station(s) of moderate to large size, ranging from 500 to 20,000 cubic feet per second. At the time of compiling this Draft GRR/SEIS, it is unknown as to the number of pumps that may be necessary to minimize induced flooding, the size of the pumps, or the location of pumps within the watershed, or the effectiveness of this measure as compared to nonstructural measures. Additional analysis will likely be conducted during the Preconstruction Engineering and Design (PED) phase to determine the above and appropriate supplemental NEPA analysis and coordination would be conducted as necessary.

Preliminary analyses undertaken during the development of alternative plans indicate expected technical challenges and inefficiencies associated with utilizing pumps for reducing induced flooding. Therefore, the current mitigation analysis excludes pump stations and focuses on potential application of nonstructural measures, as described in the following sections.

Nonstructural Measures: Nonstructural mitigation measures considered included dry and wet floodproofing, structure elevation, and buyouts and relocations. Dry floodproofing involves sealing flood prone structures from water with door and window barriers, small scale rapid deployable floodwalls, or sealants. A sump pump and drain system may be required as part of the project to remove seepage or interior drainage. Dry floodproofing is generally feasible and effective up to a maximum height of three to four feet above ground level. Wet floodproofing does not prevent water from entering the structure but moves or protects damageable items from the water so that once the surge recedes, the damage to the structure and contents is greatly reduced and re-establishment accelerated. Wet floodproofing can include evacuating the first floor, elevation of contents/utilities, and/or installation of flood vents to reduce hydrostatic forces on exterior walls. Floodproofing is only recommended for non-residential structures, such as commercial buildings and critical infrastructure that cannot be elevated due to their large size. Elevation of structures is limited to residential structures. Whether a structure may be elevated depends on several factors including the foundation type, size of the structure, condition, etc. The goal of elevating a home is to modify the structure so that the finished floor is at a height where it is less likely that the structure and/or contents will be damaged by flooding.

Additional analysis would be conducted during PED to determine the precise number and location of structures recommended for dry/wet floodproofing, elevation, or acquisition, as well as to reconsider other structural mitigation measures, as appropriate. Supplemental NEPA analysis and coordination would be conducted in subsequent phases of the project, as appropriate, to ensure proper consideration is given to required mitigation actions.

Table 53 shows structure/occupancy type and the associated nonstructural mitigation action that would be appropriate . Single-family residential structures that are one or two story with no

basement would be recommended to be elevated. Commercial Structures would be dry floodproofed, and hotels and multi-family (apartment) structures would be wet floodproofed by evacuating the first floor. All floodproofing and structure elevation actions would be below four feet and 12 feet, respectively.

Table 53: Number of residential (RES), commercial (COM), industrial (IND), and public (PUB) structures assessed for nonstructural mitigation within each study reach under the 5% and 1% AEP flood events.

	5% AEP Event					1% AEP Event

Total	13	28	4	3	48	27	32	5	6	70

Mitigation for the 5% AEP Event

A total of 48 structures within seven study reaches were identified as having expected induced flooding at the 5% AEP flood event, including 35 non-residential structures and 13 residential structures (Table 53; see Figure 2 for location of each study reach). Six structures would be recommended for elevation, eight structures for evacuation and wet floodproofing of the first floor, and 34 structures for dry floodproofing. No structures that would be candidates for dry floodproofing have greater than 4 feet of flooding. Table 54 shows the number of structures appropriate for elevation, dry floodproofing, or evacuation and wet floodproofing of the first floor per study reach to mitigate for induced flood risk under the 5% AEP event.

Table 54: Nonstructural Induced Flooding Mitigation by Reach (5% AEP).

Reach	Elevate	Dry Floodproof	Evacuate First Floor & Wet Floodproof	Total
AW1	0	1	0	1
AW2L	0	0	1	1
AW2R	0	19	3	22
AW4	1	0	0	1
AW6	1	7	2	10
AW7R	3	0	2	5

Reach	Elevate	Dry Floodproof	Evacuate First Floor & Wet Floodproof	Total
AW8L	1	7	0	8
Total	6	34	8	48

The study team developed rough order of magnitude costs for nonstructural mitigation using existing USACE studies, including studies in American Samoa and North Carolina. Mitigation costs were developed and included for the 48 structures with mitigation measures at the 5% AEP event. Construction costs were assumed to be $500,000 per structure and included 100% contingency to address uncertainties in implementation of nonstructural measures, including mitigation action and construction costs. Utilizing these cost estimates and assumptions, construction associated with elevation and floodproofing measures for the 48 structures included for mitigation under the 5% AEP event are $48,000,000. Anticipated costs also include $2,400,000 in temporary relocations ($50,000 per structure); real estate review and administration costs $384,000 ($8,000 per structure); $8,640,000 (18%) for planning, engineering and design; and $3,360,000 in construction management (7%). Total mitigation costs for elevating and floodproofing structures under the 5% AEP event are $62,784,000.

The estimate above assumes that real estate is not compensable and impacted property owners will be offered the opportunity to voluntarily participate in non-structural mitigation measures described above. Purchasing of the real estate and relocation of the 48 structures with induced flooding at the 5% AEP flood event would cost approximately $239,000,000.

Mitigation for the 1% AEP Event

A total of 70 structures within nine study reaches were identified as having induced flooding at the 1% AEP flood event, including 43 non-residential structures and 27 residential structures (Table 53). Twelve structures would be recommended for elevation, 16 structures for evacuation and wet floodproofing of the first floor, and 42 structures for dry floodproofing. No structures that were candidates for dry floodproofing (non-residential) had greater than 4 feet of flooding. Table 55 shows the number of structures appropriate for elevation, dry floodproofing, or evacuation and wet floodproofing of the first floor per study reach in order to mitigate for induced flood risk under the 1% AEP flood event.

Table 55: Nonstructural Induced Flooding Mitigation by Reach For The 1% AEP Event

Reach	Elevate	Dry Floodproof	Evacuate First Floor & Wet Floodproof	Total
AW1	0	1	0	1
AW2L	0	0	1	1
AW2R	3	22	10	35
AW4	3	0	1	4
AW5	0	1	0	1
AW6	2	5	2	9
AW7L	0	1	0	1
AW7R	3	5	2	10
AW8L	1	7	0	8
Total	12	42	16	70

Utilizing the same cost estimates and assumptions described above, construction of nonstructural mitigation measures for the 70 structures included for mitigation under the 1% AEP event are $70,000,000. Anticipated costs also include $3,500,000 in temporary relocations ($50,000 per structure); $560,000 in associated real estate review and administration costs ($8,000 per structure); $12,600,000 for planning, engineering and design (18%); and $4,900,000 in construction management (7%). Total mitigation costs for induced flooding under the 1% AEP event are $91,560,000.

The estimate above assumes that real estate is not compensable and impacted property owners will be offered the opportunity to voluntarily participate in non-structural mitigation measures described above. Purchasing of all real estate and relocation of the 70 structures with greater than 0.5 feet of induced flooding at the 1% AEP event would cost in excess of $2,000,000,000.

Proposed Mitigation
The study team acknowledges recent case law regarding what level of induced flooding constitutes a takings (i.e., requires purchase of affected properties and relocation of affected inhabitants away from the flood hazard) that may change how USACE interprets and implements policy regarding induced flooding. The study team will include those potential risks in discussions and analyses moving forward. Given this uncertainty, the study team recommends incorporating $300,000,000 in potential mitigation costs. These costs are expected to cover a combination of acquisition and relocation or elevation/floodproofing of all 70 structures with induced flooding under the 1% AEP event. Potential mitigation scenarios that could be covered by the $300,000,000 include elevation and floodproofing of all 70 structures ($91,560,000) or acquisition and relocation of all 48 structures with induced flooding under the 5% AEP and elevation/floodproofing of the remaining structures with induced flooding under the 1% AEP ($292,000,000).

5.3 Cost Estimate

The project first cost (October 2023 price level) of the TSP is summarized in Table 56; additional detail is provided in the Cost Engineering Appendix (Appendix G). Costs for the structural components alone and with expected mitigation for induced flooding at the 1% AEP event are shown. The project first cost (constant dollar cost) serves as the basis for providing the cost of the project for which authorization is sought; it includes costs associated with (1) PED, (2) construction (including mitigation activities for impacts to aquatic habitat and cultural resources), (3) lands, easements, rights-of-way, relocations and disposal (LERRD), and (4) contingencies. In accordance with ER 1110-2-1302 and Engineering Construction Bulletin (ECB) 2007-17, a cost and schedule risk analysis will be conducted, prior to the release of the Final Report, to identify and measure the cost impact of project cost uncertainties. Contingencies will be identified using a Cost-Schedule Risk Analysis.

Table 56 displays updated costs for the optimized TSP, Alternative 5.3. Total project first costs associated with the structural features are $774.5 million, and the average annual cost is $29.8 million at an FY23 2.5% discount rate. With nonstructural mitigation, total project firsts costs are $1.075 billion. The total average annual cost including nonstructural mitigation is $40.4 million at an FY23 2.5% discount rate.

Table 56: Alternative 5.3 (TSP) Cost Summary Without (Structural Components Only) and With Nonstructural Measures to Mitigate for Induced Flooding During the 1% AEP Event

Category	Alternative 5.3 w/o Mitigation ($1000's, FY23 Price Levels)	Alternative 5.3 w/ Mitigation ($1000's, FY23 Price Levels)
Construction Cost	$570,904	$570,904
Lands and Damages	$58,089	$58,089
Planning, Engineering, and Design	$105,617	$105,617
Construction Management	$39,963	$39,963
Nonstructural Mitigation	-	$300,000
Total Project First Costs	$774,574	$1,074,573
Interest During Construction	$59,462	$60,390
Total Gross Investment	$834,036	$1,134,963
Annual Cost of Total Gross Investment	$29,406	$40,017
Annual OMRR&R	$359	$359
Average Annual Cost	$29,765	$40,376

Table 57shows average annual net benefits for the TSP with and without the nonstructural mitigation measures for reducing induced flooding, which are $22.5 million and $17.9 million, respectively. The BCR for the TSP with and without nonstructural mitigation measures is 1.8 and 1.4, respectively, at an FY23 discount rate of 2.5%.

Table 57: Alternative 5.3 (TSP) Benefit-Cost Evaluation Without (Structural Components Only) and With Nonstructural Measures to Mitigate for Induced Flooding During the 1% AEP Event.

Category	Alternative 5.3 w/o Mitigation ($1000's, FY23 Price Levels)	Alternative 5.3 w/ Mitigation ($1000's, FY23 Price Levels)
Equivalent Average Annual Benefits	$52,303	$58,252
Average Annual Costs	$29,765	$40,376
Net Annual Benefits	**$22,537**	**$17,876**
Benefit to Cost Ratio	**1.8**	**1.4**

5.4 Implementation of the Tentatively Selected Plan

The tentatively selected plan is estimated to be at approximately a 10% design level and is based upon current information and the best available estimates and projections of future conditions in the study area. Therefore, modifications to the project design and operations are likely during later stages of project design and construction to ensure that the project considers any unforeseen changes in the existing or future conditions that have occurred since the completion of this Draft GRR/SEIS. Modifications may require new investigation into environmental and social impacts. There are also some analyses that have been deferred to or must occur during the PED phase when more detailed plans and specifications are developed, including:

- Detailed cultural resources surveys.
- Review of conditions that may have changed since the completion of the feasibility study that would affect the design of structural or nonstructural measures included in the tentatively selected plan.

- Detailed assessment of structures identified for nonstructural measures, including but not limited to surveys, structural assessments, etc.
- Any additional environmental coordination that may be required if there are environmental, cultural, and/or historic resource impacts that were not identified during the feasibility study.

This feasibility study was delegated to the Pittsburgh District. Once the Ala Wai Canal General Reevaluation Study is complete, the Pittsburgh District will transfer the study documentation to the Honolulu District, which will immediately assume responsibility for the design and construction of the project.

5.5 Participation in Nonstructural Measures

The tentatively selected plan includes elevation of residential homes and floodproofing of non-residential structures throughout the Ala Wai watershed. The primary economic analysis assumes 100% participation of the structures included in the tentatively selected plan. The total project cost that is ultimately authorized into law will be the estimated cost to implement 100% of the structures recommended for nonstructural measures. However, these measures will be implemented on a voluntary basis and structure owners may choose to participate in the project. Thus, participation rates could affect the overall cost and benefits associated with the TSP. Differing participation rates are not expected to affect the overall viability of the TSP given that the Alternative 5.3 represented the NED plan both without application of nonstructural mitigation measures and with 100% participation across the 70 structures for which nonstructural mitigation was considered.

5.6 Lands, Easements, Rights-of-Way, Relocations, and Disposal

The estimated real estate cost associated with the TSP is approximately $58,088,600, including all recommended lands, easements, rights-of-way, relocations, and disposals (LERRDs), relocations, incremental real estate contingency, administrative costs to be carried out by the NFS, and Government costs for LERRDs monitoring and certification. Preliminary analyses undertaken during the development of alternative plans indicate expected technical challenges and inefficiencies associated with utilizing pumps for reducing induced flooding. Therefore, the current mitigation analysis excludes pump stations and focuses on potential application of nonstructural measures. Real estate considerations for nonstructural measures, described previously in this report, are included in this estimated real estate cost. Additionally, further analysis is needed regarding induced flooding and real estate takings. Due to recent Federal Circuit legal opinions, a conservative range of estimated buyouts is assumed, which indicates a fee simple value ranging from $124.55M to $5.47B. However, due to the uncertain outcome of this analysis as well as the additional analysis related to nonstructural mitigation measures, the estimated value of buyouts is not included in the estimated real estate cost associated with the TSP.

The NFS is responsible for providing all LERRDs required for the construction, operation, and maintenance of the project. The NFS is instructed to acquire the minimum real estate interests necessary for the project. LERRDs required for the proposed project include:

Flowage Easement (permanent)

- Ala Wai Golf Course Detention Basin: 128.35 acres

The minimum estate required for the detention basins is a permanent flowage easement totaling approximately 128.35 acres.

Flood Protection Levee Easement
- Ala Wai Golf Course Levee: 9.18 acres
- Ala Wai Golf Course Floodwall: 3.83 acres
- Koali Road Floodwall: 0.70 acres
- Woodlawn Drive Floodwall: 0.35 acres

The minimum estate required for the floodwalls is a perpetual flood protection levee easement totaling approximately 14.06 acres.

Temporary Work Area Easement
Construction and Staging Areas: 5.54 acres

The minimum estate required for construction and staging, including access, is a temporary work area easement totaling approximately 5.54 acres. The temporary work area easement is estimated to be required for two (2) years during project construction.
Utility Easement
Utility Relocations: 3.35 acres

The minimum estate required for relocation of existing sewer, water, gas, and power utilities along the Koali Road Floodwall, Ala Wai Golf Course Detention Basin, and the Ala Wai Cana Floodwall is a utility easement totaling approximately 3.35 acres. The size of the utility easement is assumed as a 20-foot wide easement.

Induced Flooding
Induced flooding is reasonably anticipated as a result of the Ala Wai Golf Course Detention Basin, Ala Wai Golf Course Floodwall, Koali Road Floodwall, and Woodlawn Drive Floodwall. Due to the significant induced flooding estimated to cover the entirety of the detention basin, a permanent flowage easement is required. Additionally, induced flooding is also anticipated as a result of the proposed floodwalls. Further legal analysis is required on a parcel-by-parcel basis regarding physical invasion takings and just compensation payment requirements. Due to recent Federal Circuit legal opinions, a conservative range of estimated buyouts is assumed, which indicates a fee simple value ranging from $124.55M to $5.47B.

5.7 Operations, Maintenance, Repair, Replacement and Rehabilitation (OMRR&R)

The federal government is responsible for preparing and providing an OMRR&R manual to the sponsor as the final Recommended Plan is being implemented. OMRR&R costs associated with this TSP are considered ‘de-minimis’ (requiring only periodic surveillance by the non-federal sponsor). If nonstructural measures are ultimately included in the final Recommended Plan, each individual property owner is responsible for maintenance of their elevated or floodproofed structure/home.

5.8 Project Risks

Residual Risk

Table 58 displays damages by event with the TSP in place for the future condition. With the TSP in place, expected annual damages (EAD) are reduced in most reaches at the 1% AEP flood event. Approximately 1,200 structures experience a reduction in flooding at the 2% AEP event in reach AW1.

Table 58: EAD by Flood Event Future Condition.

Reach	10% AEP Structures	10% AEP Damages	2% AEP Structures	2% AEP Damages	1% AEP Structures	1% AEP Damages	0.2% AEP Structures	0.2% AEP Damages
AW1	1	$51	1	$194	1	$222	77	$269
AW2L	108	$12,651	180	$22,169	200	$25,757	313	$47,607
AW2R	153	$46,227	448	$123,310	579	$159,592	765	$216,501
AW3L	18	$6,562	93	$19,973	124	$25,934	185	$41,150
AW3R	43	$8,979	86	$32,964	101	$38,988	128	$47,534
AW4	3	$39	86	$10,474	281	$32,883	632	$78,348
AW5	0	$0	1	$350	1	$1,781	3	$2,647
AW6	1	$1	18	$7,518	22	$12,079	90	$15,278
AW7L	0	$0	1	$516	3	$2,310	54	$5,203
AW7R	2	$92	15	$2,035	38	$9,284	65	$15,376
AW8L	58	$4,889	110	$11,227	126	$14,361	144	$17,848
AW8R	5	$805	36	$3,282	44	$5,085	54	$6,614
AW9L	3	$255	12	$1,010	24	$2,075	31	$3,325
AW9R	28	$3,012	56	$9,416	64	$11,983	80	$15,183
Total	**423**	**$83,564**	**1,143**	**$244,439**	**1,608**	**$342,333**	**2,621**	**$512,885**

Uncertainty

Identifying and managing risk is critical to making informed planning decisions in the face of uncertainty. However, some level of uncertainty will remain following any decision. Understanding and characterizing this remaining uncertainty is also critical as it can affect the outcome of any decision. This section characterizes uncertainty associated with each alternative.

There is a degree of uncertainty surrounding project performance given the highly complex hydrology and hydraulics of the watershed. The timing of storm and flood events can greatly impact project performance, especially pertaining to the proposed project features in the lower watershed. There is also uncertainty related to how the stormwater drainage in the study area will interact with the TSP features; detailed modeling will be conducted in PED.

5.9 Cost Sharing

All estimates are at the 2023 price level and may change due to inflation prior to construction. The non-federal sponsor must provide self-certification of financial capability as required by USACE policy. Use of funds from other federal programs, including any non-federal contribution required as a matching share, to meet financial obligations of the non-federal sponsor is not permitted unless USACE authorizes use of those funds in writing.

Project design and implementation costs are shared 65% federal and 35% non-federal. The non-federal sponsor is required to provide all LERRDs. Based on these requirements, the

estimated non-federal contribution for the structural components of the TSP is $271,101,000, which includes $36,966,000 for PED, $58,089,000 in LERRD costs, and $176,047,000 in construction costs (Table 59).

Table 59: Federal and Non-Federal Cost Share for the TSP.

	Costs ($000s) with Nonstructural Mitigation		
Construction Item	**Federal Cost**	**Non-Federal Cost**	**Total Cost**
PED*	$68,651	$36,966	$105,617
LERRDs	$0	$58,089	$58,089
Construction Costs*	$434,821	$176,047	$610,867
Subtotal	$434,821	$234,135	$668,956
Total Project	$503,472	$271,101	$774,574
	Costs ($000s) w/ Nonstructural Mitigation		
Construction Item	**Federal Cost**	**Non-Federal Cost**	**Total Cost**
PED*	$68,651	$36,966	$105,617
LERRDs	$0	$58,089	$58,089
Construction Costs*	$434,821	$176,047	$610,867
Subtotal	$434,821	$234,135	$668,956
Nonstructural mitigation	$195,000	$105,000	$300,000
Total Project	$698,472	$376,101	$1,074,573
*Construction costs include construction and construction management			

The estimated non-federal contribution for the TSP including nonstructural mitigation for induced flooding is $376,101,000 which includes $105,000,000 for mitigation in addition to the PED, LERRDs, and construction costs associated with the structural elements (Table 59).

5.10 Design and Construction

Due to the level of design for this design (approximately 5-10% level) the estimate falls into a Class 4 category, based on ER 1110-2-1302. There is still substantial lack of technical information and scope clarity resulting in major estimate assumptions in technical information and quantities, heavy reliance on cost engineering judgment, cost book, parametric, historical, and little specific crew-based costs. While certain construction elements can be estimated in detail, there is still a great deal of uncertainty relative to major construction components. For the corollary cost data, recent projects in Hawaii (including the previous Ala Wai Feasibility Study) with similar scope were used when possible to give the most reasonable similar costs.
The quantity takeoff was developed by the technical team and Cost Engineer based on preliminary design concepts. Quantities will be further refined as the project progresses through feasibility phase. Due to the preliminary stage of design, quantities may change as the design progresses. This risk will be captured in the Risk Analysis and accounted for in the contingency amounts.

Based on the MII estimate a preliminary schedule of 3 to 4 years is expected (with multiple crews on critical path items due to the large footprint of the different alternatives).

5.11 Environmental Commitments

Table 60 shows the environmental commitments that have been incorporated into the proposed project for the purpose of minimizing environmental effects.

Table 60: Summary of Environmental Commitments.

Resources Category	Environmental Commitments (Mitigation Measures)
Geology, Seismicity, and Soils	**MM GSS-1:** During construction activities, the project applicant shall incorporate the conclusions and recommendations included in the Geotechnical Investigation Appendix. Geotechnical conclusions and recommendations are in Appendix D and discuss geologic hazards such as slope stability, liquefaction, settlement potential, soil suitability, soil corrosivity, etc.
Natural Environment	**EC BR-1:** The following environmental commitments are designed to avoid or minimize impacts to fish and wildlife resources, and ESA-listed marine resources: • Authorized filling-related activities that may result in the temporary or permanent loss of aquatic habitats should be designed to avoid indirect, negative impacts to aquatic habitats beyond the planned project footprint. • Turbidity and siltation from project-related work should be minimized and contained within the project footprint by silt containment devices and curtailing work during flooding or adverse tidal and weather conditions. BMPs should be maintained for the life of the construction period until turbidity and siltation within the project footprint is stabilized. All project construction-related debris and sediment containment devices should be removed and disposed of at an approved site. • All project construction-related materials and equipment (dredges, vessels, backhoes, silt curtains, etc.) to be placed in an aquatic environment should be inspected for pollutants including, but not limited to; marine fouling organisms, grease, oil, etc., and cleaned to remove pollutants prior to use. Project related activities should not result in any debris disposal, non-native species introductions, or attraction of non-native pests to the affected or adjacent aquatic or terrestrial habitats. Implementing both a littler-control plan and a Hazard Analysis and Critical Control Point plan (HACCP – see https://www.fws.gov/policy/A1750fwl.html) can help to prevent attraction and introduction of non-native species. • Project construction-related materials (fill, revetment rock, pipe, etc.) should not be stockpiled in, or in close proximity to aquatic habitats and should be protected from

	erosion (e.g., filter fabric, etc.), to prevent materials from being carried into waters by wind, rain, or high surf. • Fueling of project-related vehicles and equipment should take place away from the aquatic environment and a contingency plan to control petroleum products accidentally spilled during the project should be developed. The plan should be retained on site with the person responsible for compliance with the plan. Absorbent pads and containment booms should be stored on-site to facilitate the clean-up of accidental petroleum releases. • All deliberately exposed soil or under-layer materials used in the project near water should be protected from erosion and stabilized as soon as possible with geotextile, filter fabric, or native or non-invasive vegetation matting, hydro-seeding, etc. **EC BR-2:** The following environmental commitments are designed to avoid and minimize potential project impacts to Hawaiian hoary bat: • Do not disturb, remove, or trim woody plants greater than 15 feet tall during the bat birthing and pup rearing season (June 1 through September 15). • Do not use barbed wire for fencing. **EC BR-3:** The following environmental commitments are designed to avoid and minimize potential project impacts to Hawaiian seabirds: • To the maximum extent practicable, limit construction activities to the time between dawn and dusk to avoid the illumination of adjacent habitat areas. • If construction activity time restrictions are not possible, use down shielding or directional lighting to avoid light trespass into bird habitat (i.e., use a 'Cobra' style light rather than an omnidirectional light system to direct light down to the roadbed). To the maximum extent practicable, while allowing for public safety, low intensity energy saving lighting (e.g., low pressure sodium lamps) will be used. • Minimize illumination of lighting on associated construction or operation structures by using motion sensors or heat sensors. • Bright white light, such as metal halide, halogen, fluorescent, mercury vapor, and incandescent lamps should not be used. • Fully shield all outdoor lights so the bulb can only be seen from below bulb height and only use when necessary. • Install automatic motion sensor switches and controls on all outdoor lights or turn off lights when human activity is not occurring in the lighted area. • Avoid nighttime construction during the seabird fledgling period, September 15 through December 15.

	EC BR-4: The following environmental commitments are designed to avoid and minimize potential project impacts to Hawaiian waterbirds: • In areas where waterbirds are known to be present, reduced speed limit signs will be posted to inform project personnel and contractors about the presence of endangered species on—site; and reduced speed limits will be implemented. • Applicable USFWS BMPs regarding work in aquatic environments will be incorporated and implemented into the project design if water resources are located within or adjacent to the project footprint in order to contain stream sediments to the operational area. • A biological monitor that is familiar with Hawaiian waterbirds' biology will conduct nest surveys where appropriate habitat occurs within the vicinity of the proposed project footprint prior to project initiation. Surveys will be repeated within three days of project initiation and after any subsequent delay of work of 3 or more days (during which the birds may attempt to nest). If a nest or active brood is found: o The USFWS will be contacted within 48 hours for further guidance. o A 100-foot buffer will be established and maintained around all active nests and or broods until the chicks have fledged. Potentially disruptive activities will not be conducted, and habitat alteration will not occur within this buffer. o A biological monitor that is familiar with the species' biology will be present on the project footprint during all construction or earth moving activities until the chicks fledge to ensure that Hawaiian waterbirds and nests are not adversely impacted. **EC BR-5:** The following environmental commitments are designed to avoid and minimize potential project impacts to green sea turtle, hawksbill sea turtle, and Hawaiian monk seal: • Constant vigilance shall be kept for the presence of ESA-listed marine species during all aspects of the proposed action, particularly in-water activities. • The USACE shall designate an appropriate number of competent trained observers to survey the areas adjacent to the proposed action for ESA-listed marine species. • Surveys shall be made prior to the start of work each day, and prior to resumption of work following any break of more than one-half hour. Periodic additional surveys throughout the workday are strongly recommended. o Special attention will be given to verify that no ESA-listed species are in the area where equipment or material is expected to enter the water where there is a risk of contact with the species.

	○ Certain activities may require additional surveys as advised by NMFS on an *ad hoc* basis as identified during the consultation. • All work shall be postponed or halted when motile ESA-listed marine species are within 164 feet (50 meters) of the proposed work and shall only begin/resume after the animals have voluntarily departed the area. ○ If ESA-listed motile marine species are noticed within 164 feet (50 meters) after work has already begun, that work may continue only if the activity will not adversely affect the animal(s). For example, divers performing underwater work such as monitoring or surveys would likely be permissible, whereas operation of heavy equipment is likely not. • All objects will be lowered to the bottom (or installed) in a controlled manner to avoid contact with ESA-listed species. This can include the use of buoyancy controls such as lift bags, or the use of cranes, winches, or other equipment that affect positive control over the rate of descent. • Do not attempt to feed, touch, ride, or otherwise intentionally interact with any ESA-listed marine species. • Report any monk seal sightings: ○ Email NMFS at pifsc.monksealsighting@noaa.gov ○ Call the Marine Animal Stranding, Entanglement, and Reporting Hotline at: 888-256-9840. • No contamination of the marine environment shall result from project-related activities. • A contingency plan to control toxic materials is required. • Appropriate materials to contain and clean potential spills shall be stored at the work site and be readily available. • Heavy equipment in and near water bodies shall consider the use of biofuels and non-petroleum-based hydraulic fluids. • All project-related materials and equipment placed in the water shall be free of pollutants. • The contractor and heavy equipment operators shall perform daily pre-work equipment inspections for cleanliness and leaks. All heavy equipment operations shall be postponed or halted should a leak be detected and shall not proceed until the leak is repaired and equipment cleaned. • Fueling of land-based vehicles and equipment shall take place at least 164 feet (50 meters) away from the water, preferably over an impervious surface.

	• Turbidity and siltation from project-related work shall be minimized and contained through the appropriate use of erosion control practices, effective silt containment devices, and the curtailment of work during adverse weather and tidal/flow conditions. • A plan shall be developed to prevent debris and other wastes from entering or remaining in the marine environment during the project. • All work shall be postponed or halted when motile ESA-listed marine species are within 164 feet (50 meters) of the proposed work and shall only begin/resume after the animals have voluntarily departed the area. • Minimize direct contact to corals, seagrass, or other sessile ESA-listed resources. • All work shall be postponed or halted when motile ESA-listed marine species are within 164 feet (50 meters) of the proposed work and shall only begin/resume after the animals have voluntarily departed the area. • Unauthorized Take – If a listed marine mammal is determined by the PSO to have been disturbed, harassed, harmed, injured, or killed (e.g., a listed marine mammal(s) is injured or killed or is observed entering a shutdown zone before operations can be shutdown), it will be reported to NMFS within one business day to Ron.Dean@noaa.gov. These PSO records, submitted in digital and guervable format to NMFS, will include: o Information to be provided in the final report; o Number and species of listed animals affected; o The date, time, and location of each event (provide geographic coordinates); o Description of the event; o The time the animal(s) was first observed or entered the shutdown zone, and, if known, the time the animal was last seen or exited the zone, and the fate of the animal; o Mitigation measures implemented prior to and after the animal was taken; o If a vessel struck a marine mammal, the contact information for the PSO on duty, or the contact information for the individual piloting the vessel if there was no PSO on duty; o Photographs or video footage of the animal(s) (if available). • Stranded, injured, sick, or dead marine mammal (not associated with the project); o If PSOs observe an injured, sick, or dead marine mammal (i.e., stranded marine mammal), they will notify the Pacific Islands Marine Mammal Stranding Hotline at 888-256-9840. The PSOs will submit photos and data that will aid NMFS in

	determining how to respond to the stranded animal. Data submitted to NMFS in response to stranded marine mammals will include date/time, location of stranded marine mammal, species and number of stranded mammals, description of the stranded marine mammal's condition, event type (e.g., entanglement, dead, floating), and behavior of live-stranded marine mammals. • All areas of temporary waterway or wetland fill will be restored to their original contour and character upon completion of the project. Temporary fil includes both fill that received authorization and fill that inadvertently enters a water of the U.S. (i.e., from slope failures, accidental broken sandbag cofferdams, etc.). All temporary fills and structures in waters of the U.S. will be removed in their entirety upon completion of use. This avoidance and minimization measure will ensure restoration of flow to waterbodies for fish migration and avoids creation of potential sources of sedimentation and erosion that may elevate turbidity and adversely impair water quality conditions of downstream waters where federally listed marine species may occur. • All in-water excavation will be conducted within a cofferdam or other sediment containment device extending from the water surface to the substrate intended to isolate and contain in the work area. All in-water sediment containment devices will be placed to isolate the minimum area necessary to complete the work and will be removed upon completion of in-water work only after the water quality in the enclosed area has returned to ambient and would not release a turbidity plume. This avoidance and minimization measure isolates and contains sediments to the in-water work area and reduces potential for adverse impairment of water quality conditions with the rick of degrading water quality conditions of downstream waters where federally listed marine species may approach the in-water work area (I.e., Ala Wai Canal), the sediment containment device will create a physical barrier preventing interaction and potentially physical impact to federally listed marine species. • All upland areas of disturbed soil will be mulched and seeded with an approved native or noninvasive herbaceous seed mix following construction and/or planted with native or noninvasive woody vegetation and trees appropriate during the first available planting season. In areas where there is little to no slope and erosion and invasive species establishment is unlikely, the native woody vegetation on the site will be allowed to regenerate naturally. This avoidance and minimization measure avoids creation of potential sources of sedimentation and erosion that may

	elevate turbidity and adversely impact water quality conditions of downstream waters where federally listed marine species may occur. • Temporary access roads placed in the riparian area will be constructed in a manner that they do not allow erosion into waters of the U.S. during construction. This avoidance and minimization measure avoids creation of potential sources of sedimentation and erosion that may elevate turbidity and adversely impair water quality conditions of downstream waters where federally listed marine species may occur. • All off-road equipment and vehicles operation from existing open and maintained roads must be cleaned prior to entering the construction site to remove all soil, seeds, vegetation, or other debris that could contain seeds or reproductive portions of plants. All equipment will be inspected prior to off-loading to ensure that they are clean. This avoidance and minimization measure minimizes the spread of invasive plants that may degrade riparian habitats and erode sediments, resulting in reduced water quality conditions that may negatively affect green and hawksbill sea turtles and the Hawaiian monk seal. • During construction, any disturbed soils will be temporarily stabilized with materials such as hay, mulch, plastic sheeting, erosion control mix, or other appropriate measures. This avoidance and minimization measure reduces the risk of erosion and exposure to reduced water quality conditions that may otherwise negatively affect green and hawksbill sea turtles and the Hawaiian monk seal. • Cofferdam materials will be fully removed from the stream immediately following completion of in-water work, minimizing delays due to high stream flows following heavy precipitation. All areas of temporary bottom disturbance will be restored to their original contour and character upon completion of the project. This AMM removes obstacles and barriers to fish passage and returns benthic habitat to its original composition, limiting sediment disturbance and the temporary effects of degraded water quality conditions to green and hawksbill sea turtles and the Hawaiian monk seal. • All cofferdams will be removed using techniques to minimize turbidity releases. This includes allowing for the slow reintroduction of water into the work area and utilizing dirty water treatment systems for turbid water. This AMM avoids degrading water quality conditions that may negatively affect green and hawksbill sea turtles and the Hawaiian monk seal. • No equipment, materials, or machinery will be stored, cleaned, fueled, or repaired within any water of the U.S. All

		vehicle and equipment refueling activities will occur more than 100 feet from any water course and if not, all refueling areas will require fuel spill containment structures. A spill prevent and response plan will be prepared and implemented by the construction contractor. This AMM avoids creation of a pollutant source that may degrade downstream water quality conditions where federally listed marine species may occur. • All pumps and generators will have appropriate spill containment structures and/or spill remediation materials available, such as absorbent pads. This AMM reduces the risk of green and hawksbill sea turtle and Hawaiian monk seal exposure to petroleum products and other contaminants. • All equipment used for in-stream work will be cleaned of external oil, grease, dirt, and mud such that turbid water does not enter any water of the U.S. Any leaks or accumulations of these materials will be correlated before entering streams of areas that drain directly to streams or wetlands. All releases into surface waters or wetlands will be reported immediately to the appropriate regulatory body. This AMM reduces the risk of green and hawksbill sea turtles and the Hawaiian monk seal exposure to petroleum products and other contaminants.
Hydrology and Hydraulics	**EC HH-1:**	Potential pump station(s) located within the vicinity of Makiki Stream to minimize induced flooding. The location, size, and number of pumps that may be required will be analyzed and detailed during PED. Generally, due to the cost of this mitigation measure it is highly unlikely that this proposed mitigation measure would be implemented.
	EC HH-2:	Dry and/or wet floodproofing commercial structures in areas where induced flooding occurs. The number of structures and the location of structures that would need to be dry and/or wet floodproofed will be analyzed and detailed during PED.
	EC HH-3:	Elevating residential structures in areas where induced flooding occurs. The number of structures and the location of structures that would need to be elevated will be analyzed and detailed during PED.
	EC HH-4:	Acquisition of commercial and/or residential structures in areas where induced flooding occurs. The number of structures and the location of structures that would need to be acquired will be analyzed and detailed during PED.

Noise	**MM NV-1:**	Obtain a community noise permit from the City of Honolulu.
	MM NV-2:	Appropriate level of sound attenuation would be used during construction to meet local ordinances. Potential sound attenuation measures that could be considered include, but are not limited to, temporary sound barriers between the sources of construction noise and noise-sensitive receptors, as appropriate.
	MM NV-3:	Residents and businesses near the construction sites would be provided with advance notice of project activities, schedule, anticipated traffic, and potential noise issues. The advance notice would describe the potential noise disruption and the steps that would be taken to minimize the noise.
	MM NV-4:	Haul trucks operating near sensitive receptor sites would be spaced apart to avoid noise effects from simultaneous operation.
	MM NV-5:	Engineer brake (jake brake) use within city limits would be prohibited. Many noise complaints arise from heavy truck use of engine brakes to slow the truck down. Use of this type of braking can be avoided by proper speed control.
	MM NV-6:	The contractor would properly maintain and tune engines of all equipment and maintain properly functioning mufflers on all internal combustion engines to minimize noise levels.
Cultural Resources	**EC CUL-1:**	Historic buildings, bridges, and walls affected by construction would undergo appropriate historic documentation, and design input would be solicited from SHPO and interested consulting parties and incorporated into the final design where feasible. Where possible, impacts to archaeological resources would be avoided. Where avoidance is not possible, data recovery would be performed. Where practicable, construction measures would be microsited either up or downstream to minimize the impacts to features of Native Hawaiian cultural significance (Traditional Cultural Property [TCPs]) that could be disturbed by project actions.
	EC CUL-2:	Design input to minimize visual impacts to the greatest extent possible will be solicited from SHPO and interested consulting parties, and incorporated, as

		feasible, into the final design and construction of floodwalls.
	EC CUL-3:	If previously unknown cultural resources are discovered, work in the immediate area would cease until the requirements in 36 CFR 800.13 are complied with. The on-site supervisor shall contact the USACE's Project Manager and District Archaeologist, and an approved archaeological consultant immediately. The on-site supervisor shall additionally divert all Proposed Action-related activities to other areas until the discovery has been evaluated by the approved archaeological consultant. The USACE will determine if further mitigation measures are warranted in consultation with the SHPO and consulting parties.
	EC CUL-4:	Design of the Ala Wai Canal floodwalls includes an elevated walkway where feasible. In addition, as per the PA, design input to further minimize visual impacts to the greatest extent possible will be solicited from SHPO and interested consulting parties, and incorporated, as feasible, into the final design and construction of the floodwalls. The appropriate level of historic documentation of the Ala Wai Canal will also be developed with SHPO and other consulting parties.
Land Use and Planning	**EC LUP-1:**	Phase construction to ensure there is adequate temporary housing available due to scarcity of housing in the area.
	EC LUP-2:	Simultaneously implement nonstructural measures for whole blocks or streets of residences so that construction windows within neighborhoods can be minimized.
Aesthetics	**Refer to Cultural Resources, EC CUL-4.**	
Transportation and Traffic	**MM TT-1:**	Construction contractor would be required to prepare and implement a Transportation Management Plan. Measures to be included in the plan are expected to include the following: • Institute time-of-day restrictions for large, oversized construction vehicles to minimize interference with peak-hour or commute traffic. • Maintain at least one travel land on roadways to the extent possible; if complete lane closures are required, post adequate signage for potential detours or possible delays, or conduct full lane closures at night.

	• Establish temporary increases in lane capacity, as needed (e.g., widen existing shoulders for bypass traffic). • Provide advance warning and proper roadway signage along potential construction routes to warn motorists, residents, businesses of changes in roadway and traffic-related conditions (e.g., potential vehicles entering and exiting the roadway, etc.). • Identify safe and reasonable detours, including those needed for pedestrians and bicyclists, and provide adequate notification. • Provide written, advanced notice to property owners and businesses adjacent to construction areas. • Use pilot vehicles when slow or oversized/wide loads are being hauled. • Use flaggers, as necessary, to direct traffic when large equipment is exiting or entering public roads to minimize risk of accidents. • Provide temporary parking in nearby locations to the extent possible. • Repair surface damage to local roads used for construction haul routes to pre-construction conditions.

5.12 Project-Specific Considerations

Federal implementation of the recommended plan would also be subject to non-federal sponsor compliance with the following applicable federal laws and policies:

- Inform affected interests of the extent of protection afforded by the project no less than once each year.

- Agree to participate in and comply with applicable federal floodplain management and flood insurance programs.

- Prepare a floodplain management plan within one year of the signing of the project partnership agreement and implement the plan no later than one year following completion of project constructions as specified in Section 402 of the Water Resources Development Act of 1986, as amended (33 U.S.C. 701b-12).

- Prevent obstructions or encroachments on the project, including prescribing and enforcing regulations to prevent obstructions or encroachments, such as new developments on project lands, easements, and rights-of-way or the addition of facilities that may reduce the level of protection the project affords, hinder project OMRR&R, or interfere with project function.

- Publicize floodplain information and provide this information to zoning and other regulatory agencies for use in adopting regulations, taking other actions to prevent unwise future development, and ensuring compatibility with protection levels provided by the project.

- Comply with all applicable provisions of the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970, Public Law 91-646, as amended (42 U.S.C. 4601-4655) and the Uniform Regulations contained in 49 CFR Part 24 in acquiring lands, easements, and rights-of-way required for construction and OMRR&R of the project, including those necessary for relocations, borrowing of material, or disposal of dredged or excavated material. Inform all affected persons of applicable benefits, policies, and procedures in connection with these laws and regulations.

- For so long as the project remains authorized, complete OMRR&R requirements on the project at no cost to the Federal Government in a manner compatible with the project's authorized purposes and in accordance with applicable federal and state laws, regulations, and any specific directions prescribed by the federal government.

- Give the federal government a right to enter, at reasonable times and in a reasonable manner, upon property that the non-federal sponsor owns or controls for access to the project for the purposes of completing, inspecting, or conducting pre-completion OMRR&R on the project.

- Hold and save the U.S. free from all damages arising from the construction or OMRR&R of the project and any betterments, except for damages due to the fault or negligence of the U.S. or its contractors.

- Keep and maintain books, records, documents, or other evidence pertaining to costs and expenses incurred pursuant to the project for a minimum of three years after final accounting.

- Comply with all applicable federal and state laws and regulations, including but not limited to: Section 601 of the Civil Rights Act of 1964 (42 U.S.C. 2000d) and Department of Defense Directive 5500.11 issued pursuant thereto; the Age Discrimination Act of 1975 (42 U.S.C. 6102); the Rehabilitation Act of 1973, as amended (29 U.S.C. 794) and Army Regulation 6007 issued pursuant thereto; 40 U.S.C. 3141-3148 and 40 U.S.C. 3701-3708 (labor standards originally enacted as the Davis-Bacon Act, the Contract Work Hours and Safety Standards Act, and the Copeland Anti-Kickback Act).

- Perform, or ensure performance of, any investigations that are determined necessary to identify the existence and extent of any hazardous substances regulated under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) and Public Law 96-510, as amended (42 U.S.C. 9601-9665) that may exist in, on, or under lands, easements, or rights-of-way that the federal government determines to be required for construction and completion of OMRR&R of the project. However, for lands that the federal government determines to be subject to the navigation servitude, only the federal government shall perform such investigations unless the federal government provides the non-federal sponsor with prior specific written direction, in which case the non-federal sponsor shall perform such investigations in accordance with such written direction.

- Assume, as between the federal government and the nonfederal sponsor, complete financial responsibility for all necessary cleanup and response costs of any hazardous substances regulated under CERCLA that are located in, on, or under lands, easements, or rights-of-

way that the federal government determines to be required for construction and completion of OMRR&R of the project.

- Agree, as between the federal government and the non-federal sponsor, that the non-federal sponsor shall be considered the operator of the project for the purposes of CERCLA liability, and to the maximum extent practicable, OMRR&R the project in a manner that will not cause liability to arise under CERCLA.

- Comply with Section 221 of Public Law 91-611, Flood Control Act of 1970, as amended (42 U.S.C. 1962d-5b), and Section 103(j) of the Water Resources Development Act of 1986, Public Law 99-662, as amended (33 U.S.C. 2213(j)), which provides that the Secretary of the Army shall not commence the construction of any water resources project, or separable element thereof, until each non-federal interest has entered into a written agreement to furnish its required cooperation for the project or separable element.

5.13 Environmental Operating Principles (EOP)

This study and the associated recommended plan maintain the USACE commitment to environmental stewardship by conforming to the following USACE Environmental Operating Principles:

Foster sustainability as a way of life throughout the organization. The TSP fosters environmental sustainability by representing the plan with no significant or permanent environmental impacts. Proactively consider environmental consequences of all USACE activities and act accordingly. The study team coordinated with appropriate environmental agencies to identify all possible environmental impacts and sought avenues to minimize those impacts throughout the development and evaluation/comparison of alternative plans.

Create mutually supporting economic and environmentally sustainable solutions. The recommended plan reduces flood risk to communities throughout the study area through the implementation of measures that have no significant or permanent environmental impacts. Continue to meet our corporate responsibility and accountability under the law for activities undertaken by USACE, which may impact human and natural environments. The study team is engaged in the activities necessary to assess and minimize cumulative impacts to the environment through NEPA via necessary surveys and agency coordination. It is expected that the recommended plan will be compliant with all applicable laws and policies.
Consider the environment in employing a risk management and systems approach throughout the life cycles of projects and programs. Environmental risks were identified early in the study process and used to inform plan formulation decisions.

Leverage scientific, economic, and social knowledge to understand the environmental context and effects of USACE actions in a collaborative manner. The study team worked with local and regional stakeholders and held multiple scoping meetings with the public to obtain all existing scientific, economic, and social knowledge regarding environmental context and used this information during the plan formulation process.

Employ an open, transparent process that respects views of individuals and groups interested in USACE activities. The study team was open and transparent regarding the study process and possible outcomes during site visits and the public scoping meetings. All feedback obtained during these outreach activities was incorporated into the planning process. The recommended plan will be reviewed and potentially modified during the PED phase. If changes to the project result in effects that have not been previously evaluated, then pursuant to NEPA, USACE will prepare a separate NEPA document to address the changes and evaluate the associated effects. USACE and its contractors commit to avoiding, minimizing, and mitigating for adverse effects during construction activities.

5.14 Views of the Non-Federal Sponsor

The non-federal Sponsor (NFS), represented by the City and County of Honolulu, has expressed support of the draft plan. A letter of intent acknowledging the NFS's intent to support project implementation will be included in the final report.

Chapter 6: Compliance with Environmental Laws and Regulations

6.1 Federal Requirements

Clean Air Act of 1972, as amended, 42 USC 7401, et seq. *Full Compliance*. The TSP is not expected to violate any federal or state air quality standards, exceeds USEPA's general conformity de minimis threshold, or hinder the attainment of air quality objectives. Implementation of BMPs would minimize any potential impacts. Thus, the USACE has determined that the TSP will have no significant effects on the future air quality in the area.

Endangered Species Act of 1973, as amended, 16 USC 1531, et seq. *Partial Compliance*. In accordance with Section 7(c), the USACE obtained a list of federally listed and proposed species likely to occur in the study area. In addition, the USACE reinitiated informal consultation with the USFWS regarding the TSP and will submit the Biological Assessment to the USFWS at the same time as the Draft IFR/SEIS is released for public review (Appendix K).

Similarly, the USACE obtained a list of federally listed and proposed marine species likely to occur in the study area. USACE reinitiated informal consultation with NMFS regarding the TSP and will submit the Biological Assessment to NMFS at the same time as the Draft IFR/SEIS is released for public review (Appendix K).

Executive Order 11988, Floodplain Management. *Full Compliance*. The objective of this Executive Order is the avoidance, to the extent possible, of long and short-term adverse effects associated with the occupancy and modification of the base flood plain (1% AEP), and the avoidance of direct and indirect support of development in the base floodplain wherever there is a practicable alternative. The TSP is the only practicable way to reduce flood risk in the Ala Wai Watershed. The TSP, in combination with State and City and County of Honolulu efforts in other parts of the watershed, protect the existing urban population while providing residual risk information to the appropriate agencies making land use decisions in the area. Therefore, the TSP does not contribute to increased development in the floodplain and is in compliance with the executive order.

Executive Order 12989, Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations. *Full Compliance*. This Executive Order states that federal agencies are responsible to conduct their programs, policies, and activities that substantially affect human health of the environment in a manner that ensures that such programs, policies, and activities do not exclude persons from participation in, or deny persons the benefits of, or subject persons to discrimination under such programs, policies, and activities because of their race, color, or national origin. USEPA's environmental justice (EJ) mapping and screening tool was used to query the action area. In the EJScreen, a two-mile buffer was drawn around the study area. The EJScreen tool was used to ascertain if the TSP would have a disproportionate adverse impact on a minority population, low-income population, or child population (i.e., persons under five years of age). For the Ala Wai watershed, a low income population is considered to be present within the study area since the low income population is above the 50th percentile (Figure 29). The state percentile with regard to a low-income population is also greater when compared to the United States percentile (Figure 31). The implementation of the TSP is not expected to have a disproportionate impact on a low-income population since the project reduces flood risk and flood impacts for this population which is expected to be a beneficial impact.

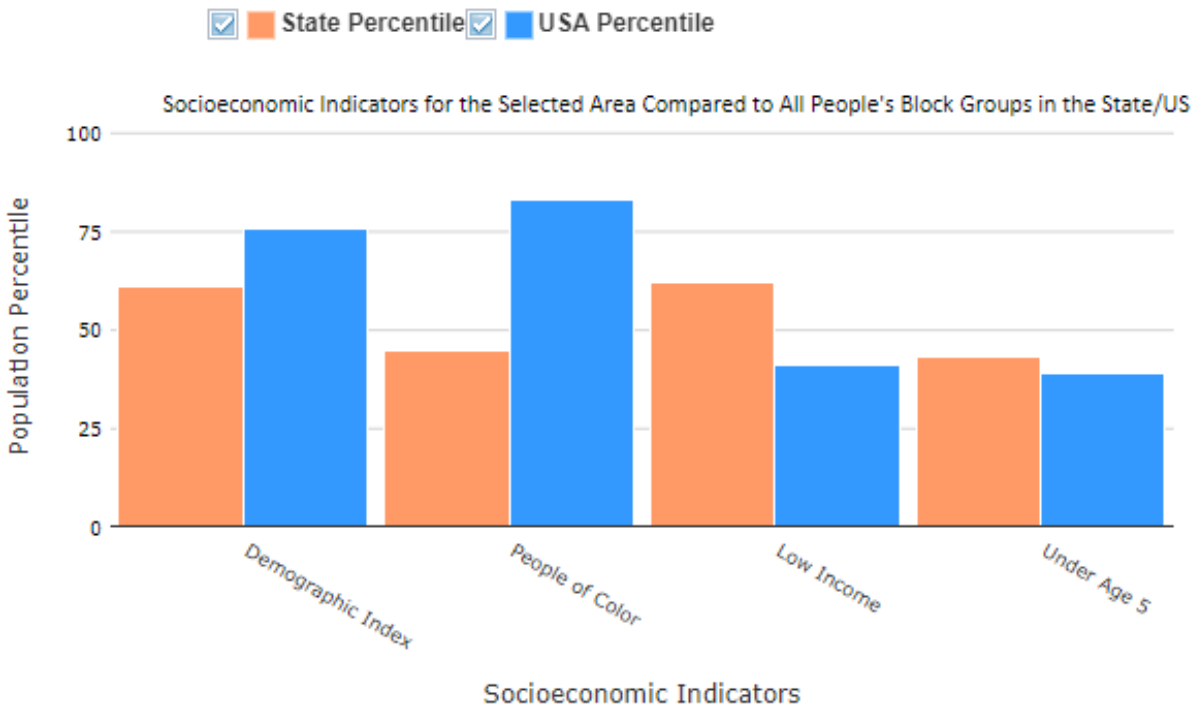

Figure 31: EJScreen Graph Depicting Socioeconomic Indicators within the Ala Wai Watershed.

Farmland Protection Policy Act, 7 USC 4201, et seq. *Full Compliance*. This act requires a federal agency to consider the effects of its actions and program son the Nations' farmland. According to Table 10, portions of the TSP are located on soils that are not prime farmland while other portions are located on soils that are prime farmland if irrigated. None of the project footprints for the TSP are currently located on farmland nor are these areas expected to be converted to farmland prior to the project being constructed. Therefore, there would be no adverse effects to farmland and the TSP is in compliance with this act.

Fish and Wildlife Coordination Act of 1958, as amended, 16 USC 661, et seq. *Partial Compliance*. This act requires federal agencies to consult with the USFWS and State fish and wildlife agencies before undertaking or approving water projects that control or modify surface water. Federal agencies undertaking water projects are required to fully consider recommendations made by the USFWS. The USACE sent a formal request to USFWS for a Fish and Wildlife Coordination Act Report on July 18, 2022 (Appendix K). The USACE received the draft Fish and Wildlife Coordination Act Report on June 22, 2023 (Appendix K).

Magnuson-Stevens Fishery Conservation and Management Act. *Partial Compliance*. This legislation requires that all federal agencies consult with NMFS regarding all actions or proposed actions permitted, funded, or undertaken that may adversely affect EFH. EFH is defined as "waters and substrate necessary to fish for spawning, breeding, feeding, or growth to maturity." The USACE reinitiated consultation with NMFS for EFH and submitted an EFH assessment will be provided to NMFS at the same time as the Draft IFR/SEIS is released for public review.

Migratory Bird Treaty Act of 1936, as amended, 16 USC 703, et seq. *Full Compliance*. This Act provides protection for migratory birds as defined in 16 USC 715.

National Environmental Policy Act of 1969, as amended, 42 USC 4321, et seq. *Partial Compliance*. This integrated GRR and SEIS is in partial compliance with this act. Comments received during the public review period will be incorporated in the GRR and SEIS as appropriate and a comments and responses appendix will be prepared. The final GRR and SEIS will be accompanied by a signed Record of Decision (ROD) if determined to be appropriate by the ASA(CW) after consideration of public comments. These actions will provide full compliance with this act.

National Historic Preservation Act of 1966, as amended (54 USC 306101, et seq.). *Partial Compliance*. Section 106 of the National Historic Preservation Act requires federal agencies to consider the effects of a proposed undertaking on properties that have been determined to be eligible for, or included in, the NRHP. The implementing regulations for Section 106 are 36 CFR § 800.

6.2 State of Hawaii Requirements

Hawaii Environmental Protection Act. *Partial Compliance*. This joint NEPA/HEPA document is in partial compliance with HEPA requirements. Comments received during the public review period will be considered and incorporated into the final GRR and SEIS, as appropriate. The Governor of Hawaii will consider accepting the GRR and SEIS to obtain full compliance with HEPA.

Hawaii Endangered Species Act. *Partial Compliance*. This act requires the non-federal agency to consider the potential adverse effect on state-listed species. As a joint NEPA/HEPA document, this GRR and SEIS will consider the potential effects and provide a determination for state listed species.

6.3 Summary of Environmental Compliance

Table 61 shows the status of environmental compliance for the proposed project with relevant laws, regulations, EOs, etc.

Table 61: Summary of Environmental Compliance.

Chapter 7: Public Involvement and Agency Coordination

Recognizing the importance of involving the public in the planning process, the USACE planning guidance specifies that open channels of communication should be developed and maintained with the public in order to give full consideration of public views and information throughout the project. Critical components of the public involvement effort should include (1) disseminating project-related information, (2) understanding the public's desires, needs, and concerns, (3) providing for consultation with the public before decisions are reached, and (4) taking into account the public's views (USACE, 2000). Public and agency involvement efforts have been conducted to comprehensively address USACE policies, as well as specific regulatory requirements for consultation. In particular, NEPA and HRS Chapter 343 require public involvement as part of the environmental review process. In addition, NHPA Section 106 requires consultation with interested parties and NHOs as part of a federal agency's consideration of the effects of their proposed undertaking on historic properties.

Based on the size of the watershed and the range of conditions, stakeholder concerns, and potential project measures and alternatives, a public engagement strategy was developed. The public engagement strategy initially included four rounds of community engagement opportunities for the community throughout the study. The first round of community engagements were to present the problem and discuss possible opportunities and potential solutions. The second round of community engagements were to discuss a more focused set of potential solutions under consideration at that stage; prior to the release of the Draft Report. The third round of community engagements were to discuss the TSP as presented in the Draft Report. The final round of community engagements were to review the Recommended Plan prior to release of the Final Report.

The public engagement strategy was refined based on feedback received during the initial public workshops to provide additional opportunities for interested parties to provide input in the study process and the development of alternative flood risk management plans. Fundamental elements of the revised public engagement strategy include:

- Continuous, virtual, asynchronous engagement through website, email, documents
- Workshops and structured meetings aligned with study milestones (hybrid – i.e., simultaneously virtual and in-person – when possible)
- Additional meetings with stakeholders for updates and focused exercises (virtual)
- Continuous, virtual, asynchronous engagement through website, email, documents

Following is a summary of the specific public and agency involvement efforts that have been conducted to date specific to this current effort. In addition, the summary below provides an overview of input received as a result of the above efforts and an overview of additional opportunities for public and agency involvement as the project moves forward. Previous coordination on this project and input received is incorporated by reference from the 2017 Ala Wai Canal Flood Risk Management Study (USACE, 2017). Additional detail and supporting information is provided in Appendix M.

7.1 NEPA and HRS Chapter 343 Scoping

Pursuant to the requirements of NEPA, an NOI was originally published on February 22, 2023 (88 FR 10880). A copy of the NOI is contained in Appendix M.

Initial Public Scoping meetings were held on November 10 and November 13, 2021. Additional scoping opportunities were also afforded through other stakeholder outreach events, including focus group meetings, as further discussed in Section 7.2.

As required by HRS Chapter 343, an EISPN was published in OEQC's Environmental Notice on April 8, 2023. Publication of the EISPN includes a 30-day comment period. A copy of the OEQC publication is contained in Appendix M.

7.2 Other Public and Agency Consultation Efforts

A significant number of stakeholder and agency meetings and other public involvement efforts have been conducted throughout the planning process to date. In general, the timing and focus of these events have been determined in response to project-related needs and stakeholder interests and desires. Events conducted specific to this Draft GRR/SEIS are summarized in Table 62.

Table 62: Summary of Public and Agency Engagement Efforts (Between June 2021 and May 2023).

Meeting Date	Meeting Type	Meeting Focus
November 10, 2021	Virtual Workshop	Problems, opportunities, and potential solutions
November 13, 2021	Virtual Workshop	Problems, opportunities, and potential solutions
January 20, 2022	Virtual Meeting	Update on public engagement strategy, process way ahead, and study schedule.
April 1, 2022	Virtual Workshop	Focused input on the Makiki and Palolo Sub-Watershed
April 8, 2022	Virtual Workshop	Focused input on the Manoa Sub-Watershed
April 14, 2022	Virtual Workshop	Focused input on the Ala Wai Canal and Lower Watershed
April 22, 2022	Virtual Workshop	Continued discussions on focused watershed discussion and question and answer opportunity
July 26, 2022	Virtual Workshop	Initial alternatives array
July 28, 2022	In-person Workshop	Initial alternatives array
December 13, 2022	Virtual Workshop	Update to the initial discussion on alternative plans being developed

7.3 Input Received Prior to Public Review

A wide range of input has been provided as part of the various public and agency meetings held to date. Following is a summary of the substantive input provided by stakeholders relative to the proposed project and the proposed flood risk management measures.

- Coordination with other projects is very important and should be considered as part of the planning and design process; key projects identified by stakeholders included the Waikiki Regional Circulator Study (which proposes a pedestrian bridge over the Ala Wai Canal).
- Proper O&M has and will always be an issue for the stream channels. Existing stream channel infrastructure is not currently maintained; the community is losing faith in local government because of the lack of support and follow through. The community can help with maintenance, but needs support.

- Many stakeholders expressed support for the project and emphasized the need for near-term action to reduce the risk of flooding. Some stakeholders questioned the need for the project, and in some cases suggested that improved stream maintenance would adequately address the existing flooding problem.
- Ala Wai Canal is a historic property (listed on National Register of Historic Places), and there is concern that the floodwalls would cause physical and visual separation between the sidewalk and the Canal, which would impact viewplanes and open space. In addition, there is concern with the height of the floodwalls. Stakeholders questioned whether the floodwalls need to be so high and/or whether they are needed on the makai side of the Canal (instead, allow open spaces to flood, with berms to protect the schools).
- Stakeholders expressed the desire for the floodwalls to be designed to match the existing historic walls.
- In addition to the visual impact of the floodwalls, other concerns expressed by stakeholders include the potential for graffiti and congregation/loitering of homeless people. Loitering is a particular concern if the floodwalls are set back from the existing Canal edge, as this would provide a corridor that is somewhat hidden and difficult to monitor.
- The floodwalls need to allow for recreational access to the Canal, both for pedestrians and canoe paddlers. The stairs on the makai side of the Canal are used by fishermen; these stairs should be maintained as access. The canoe clubs primarily use three launch locations: near McCully Bridge, at the bottom of University Avenue, and near the Golf Course at Kapahulu; consider using flood gates instead of stairs or ramps to maintain adequate access in these locations.
- Canoe clubs use the corner of Ala Wai Community Park for turning their canoe trailers. The floodwalls around the Ala Wai Canal (specifically in the area of Hausten Ditch) should be sited to maintain adequate space for the trailers.
- The amenities that are provided between Ala Wai Boulevard and the Canal (including the sidewalk, trees, landscaping and benches) are used as a linear park. Stakeholders have high expectations for this area to remain accessible and well-maintained.
- Stakeholders raised concerns about the potential of encountering pre-Contact or historic properties in the action area; there is particular concern with potential burials in the Waikiki area.
- Flapgates have high maintenance requirements, and are a liability if they fail. It is important to use high quality products.
- Need to ensure the detention basins are properly maintained and provide for emergency access. In addition, need to make sure that the berms do not pose a safety concern for recreational users.
- Stakeholders stressed the importance of not affecting the technical aspects of the golf course. For example, decreasing the length of the course would eliminate it as a venue for certain golf tournaments.
- Consider the possibility of locating the berm for the Ala Wai Golf Course detention basin away from the existing chain-link perimeter fence to allow for the fringes of the golf course to be used by the general public.
- Stakeholders requested ongoing outreach, including coordination with neighborhood boards.

As discussed throughout this document, these issues have been considered as part of the plan formulation and impact evaluation processes, and have been addressed as appropriate. All input that has been received and prepared FAQ's are found in Appendix M. In addition, information provided by the public on the 2017 Ala Wai Canal Flood Risk Management Study IFR/EIS (USACE, 2017) is incorporated by reference.

7.4 Draft Report Distribution and Public Review

Consistent with the requirements of NEPA and HRS Chapter 343, the Draft GRR/SEIS will be circulated for a 45-day public review. The review period is anticipated to start May 2023. Copies of the document will be distributed to a variety of individuals and organizations, requesting their comments on the project. In addition, a limited number of documents will be provided as loan copies in libraries, as well as online through the OEQC online library and project website.

The distribution list for the Draft GRR/SEIS was developed based on the recommended list provided by OEQC and was expanded to include all project stakeholders identified to date. This list includes federal, state, and local agencies; elected officials; community groups and organizations; adjacent landowners; libraries' and the new media. The complete distribution list and public notification postings on OEQC and the Federal Register are provided in Appendix M.

7.5 Public Comments Received and Responses

To be filled out after the 45-day public review of the Draft GRR/SEIS.

Chapter 8: District Engineer Recommendation

On the basis of the conclusions of this study, I recommend the implementation of the optimized TSP, which includes the Ala Wai Golf Course Detention Basin, Ala Wai Canal Floodwall, Kaimuki High School Floodwall, Woodlawn Drive Floodwall, and the Koali Road Floodwall. Structural and nonstructural mitigation measures would be implemented, including an integrated elevated walking path to mitigate for negative viewshed impact and the elevation and floodproofing of 70 structures to mitigate for induced flooding in specific areas throughout the watershed.

The recommendations contained herein reflect the information available at this time and current departmental policies governing formulation of individual projects. They do not reflect program and budgeting priorities inherent in the formulation of a national Civil Works construction program nor the perspective of higher review levels within the Executive Branch. Consequently, the recommendations may be modified before they are transmitted to higher authority as proposals for authorization and implementation funding. However, prior to transmittal to higher authority, the sponsors, the state, interested federal agencies, and other parties will be advised of any modifications and will be afforded an opportunity to comment further.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

1. Purpose

The purpose of the Plan Formulation Appendix is to provide additional details on the plan formulation process that were not included in the body of the main report.

2. Introduction

2.1. Planning Policy

The U.S. Army Corps of Engineers (USACE) conducts its planning efforts in accordance with the Economic and Environmental Principles and Guidelines for Water and Related Land Resources Implementation Studies, established by the Water Resources Council in 2013. The Principles, Requirements and Guidelines, referred to as the PR&G, establish federal water resource planning for the USACE, Bureau of Reclamation, Tennessee Valley Authority, and the National Resource Conservation Service. Engineering Regulation (ER) 1105-2-100, Planning Guidance Notebook, defines the specific planning policies of the USACE based on the PR&G. Federal planning efforts must comply with federal laws, including the National Environmental Policy Act (NEPA) and the Clean Water Act (CWA).

2.2. Planning Process

The USACE planning process consists of six major steps, done in iterations. The six steps are:

1. Identify problems and opportunities.
2. Inventory and forecast conditions.
3. Formulate alternative plans.
4. Evaluate alternative plans.
5. Compare alternative plans.
6. Select a plan.

Each iteration of the process is completed, in part or fully, as additional information is developed which inform the process. Figure 2-1 provides a conceptual diagram of the United States Army Corps of Engineers' (USACE) Six-Step Planning Process.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

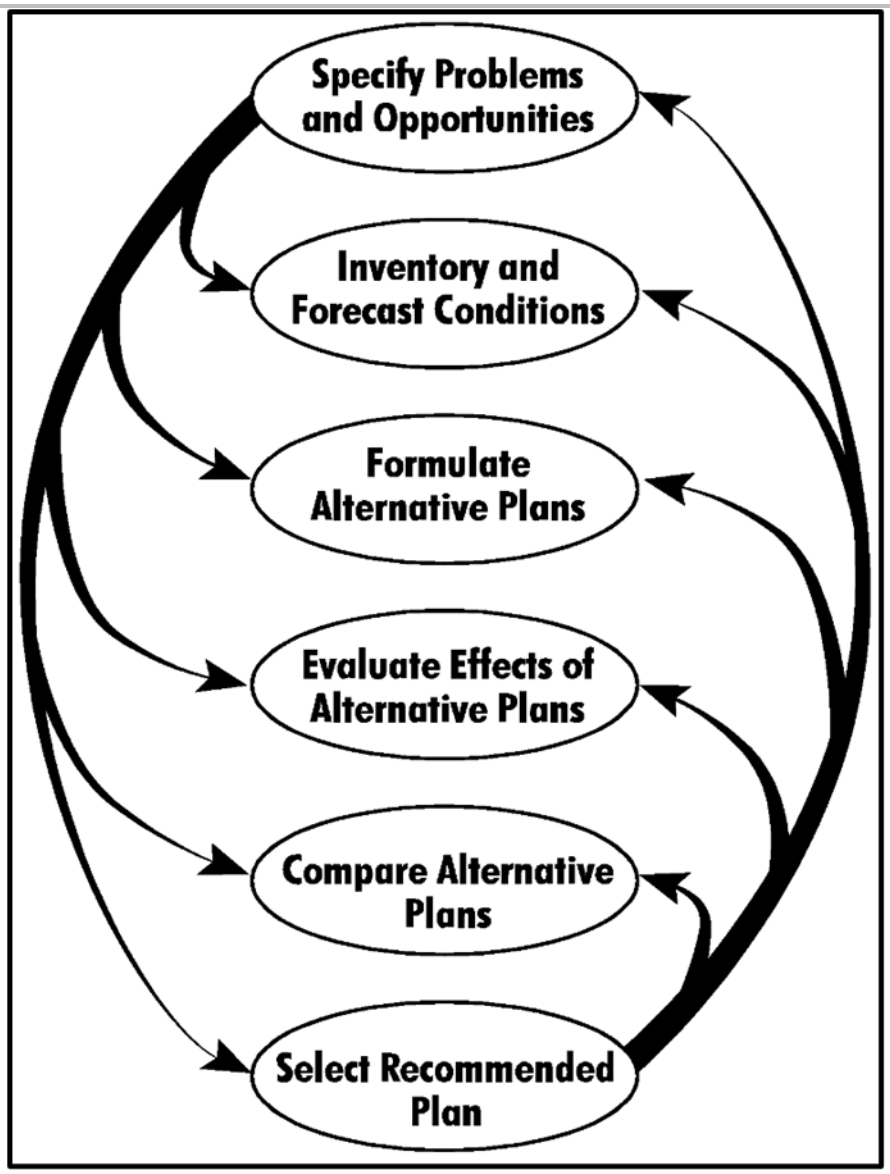

Figure 2-1: Conceptual Diagram of the USACE Six-Step Planning Process

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

3. Study Area Reach Map

The Ala Wai Watershed is located on the southeastern side of the island of Oahu, Hawaii. The watershed encompasses 19 square miles (12,064 acres) and extends from the ridge of the Ko'olau Mountains to the nearshore waters of Mamala Bay. It includes the Makiki, Manoa, and Palolo streams, which flow to the Ala Wai Canal, a 2-mile-long, man-made waterway constructed during the 1920s to drain extensive coastal wetlands. The construction and subsequent draining allowed the development of the Waikiki District. The study area was divided into 14 reaches which were informed by the hydrology and hydraulics of the watershed and intended to group structures appropriately for modeling and benefit evaluation. Figure 3-1 displays the study area reaches.

Figure 3-1: Ala Wai Reach Map

4. Preliminary Alternative Development

The initial screening of measures demonstrated that the urban nature of the study area (high land values and a lack of available real estate) tended to self-select for measures that have potential to reduce large amounts of flood risk throughout the watershed while they would likely

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

be implemented in confined areas. Based on these considerations, the following strategies were used for developing alternative flood risk management plans:

Focus on Increasing Storage – This strategy aims to reduce the risk and impacts of flooding by increasing flood water storage within existing greenspace throughout the watershed.
Focus on Improving Diversion and Drainage – This strategy aims to reduce the risk and impacts of flooding by improving drainage or diverting flood water away from the community.
Focus on Improving Channel Conveyance – This strategy aims to reduce the risk and impacts of flooding by more efficiently transporting flood waters received from the channels.
Focus on Improving Channel Capacity – This strategy aims to reduce the risk and impacts of flooding by increasing food water storage within existing channels.
Focus on Natural and Nature-Based Features (NNBFs) – This strategy aims to reduce the risk and impacts of flooding by implementing natural and nature-based features. These measures are landscape features that are used to provide engineering functions relevant to flood risk management, while producing additional economic, environmental, or social benefits.
Maximize Nonstructural and Floodproofing - This strategy aims to reduce the impacts of flooding by retrofitting existing buildings and infrastructure to be more flood resistant.

5. Measure Screening

A total of 224 individual management measures were identified either during the planning charrette or through various public involvement pathways, including the public meetings and online tools (i.e., email, online GIS applications). Management measures provided by the public during the 2017 Ala Wai Canal Flood Risk Management Feasibility Study were also considered. A full list of management measures is provided on the Management Measure Tracker spreadsheet, which can be found as Attachment A at the end of this appendix. A summary table is provided below:

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Table 5–1: Summary of Management Measures

Category	Description	Type	No.
Bridge Modification	Modify bridges identified as choke points on tributaries to increase capacity and reduce risk of adjacent inundation.	S	4
Bypass	Construction of a channel bypass to divert floodwaters away from a damage center or problem area, discharging back into the same drainage. Channel bypasses could be above or below ground, including large-scale tunnels or conduits.	S	44
Channel Modification	Widening, deepening, and/or lining of the channel to increase capacity and conveyance and prevent overtopping. Modification could occur along the tributaries, as well as the Ala Wai Canal.	S	20
Pumps	Construction of interior pumping stations to increase the rate at which floodwaters drain, reducing inundation extents and durations.	S	9
Debris Management	Measures designed to strategically capture debris during high-flow events to reduce downstream risks (e.g., direct damage and blockage/altered hydraulics).	S	11
Detention	Detention basins to store water either on (online) or off (offline) the stream network during high-flow events. Offline detention could be above ground within existing open space and/or underground.	S	58
Floodwall/Levee	Construction of a floodwall or levee along the Ala Wai Canal (i.e., construction of new floodwall or raising of existing canal walls) or its tributaries to reduce risk of inundation in adjacent areas. Floodwalls and levees could be integrated into more aesthetic, park-like features.	S	14
Gates	Control structures within or at the outlet of the Ala Wai Canal to permit lowering the water level and increasing storage and/or controlling tidal and storm surge influence. Also includes flap gates on existing drainage systems.	S	6
Grade Control Structure	Construction of grade control structures (e.g., weirs, stilling basin) to slow water velocities in the tributaries, reducing peak flows downstream and decreasing erosion and sediment.	S	6
Other	Structural measures that do not fit cleanly into more common management measure types.	S	3
Nonstructural	Physical (e.g., acquisition and relocation, floodproofing, and elevation) and nonphysical (e.g., flood warning system, risk communication, education, and planning) measures.	NS	10
Reforestation	Actions taken to protect, preserve, manage, and restore natural resources at the watershed scale (e.g., reforestation and restoring native vegetation) that restore natural process and reduce flood risk.	NNB	8
Water Quality	Measures, such as filter strips, that could be implemented in coordination with other flood risk management measures to improve water quality, as permitted by USACE policy.	NNB	4
Wetland/Floodplain	Creation or restoration of wetlands, riparian areas, and floodplains within available open space to store and dissipate flood waters.	NNB	11
Channel Naturalization	The process of restoring the geomorphic characteristics of natural stream channels, such as geometry, access to adjacent floodplains, and meanders, to increase the natural capacity of the river and reduce flood risk. This measure could also include restoring the natural stream bed and daylighting.	NNB	6
Impervious Surface Reduction	Reduce impervious surfaces and increase pervious surfaces (e.g., pervious pavement, green roofs) to reduce runoff and promote infiltration.	NNB	9
No Action	No measures would be implemented by the federal government to achieve the planning objectives.	NA	1

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

All 224 management measures were evaluated and either retained or screened from further consideration prior to alternative formulation. Management measure screening was conducted in two phases. Phase 1 involved a high-level assessment of engineering feasibility and policy compliance. Measures remaining after phase 1 screening were then tiered to prioritize additional analyses and maximize analytical efficiency. Phase 2 screening criteria are provided below in Table 2. When possible, existing data were used for screening during phase 2.

Table 5–2: Management Measure Screening Criteria

Criteria	Account	Description	Metric(s)
Efficiency	NED	Cost effectiveness—comparison of economic benefits and project costs.	Semi-quantitative – comparison of preliminary costs and expected benefits
Effectiveness (Damages Reduced)	NED	Damages to buildings, related contents, and vehicles.	Semi-quantitative – expected benefits based on previous study iterations
Effectiveness (Life Safety)	OSE	Changes in life safety risk expected with alternative implementation.	Semi-quantitative – expected benefits based anticipated water surface elevation reductions.
Acceptability	OSE	Workability and viability with respect to acceptance by State and local entities and the public and compatibility with existing laws, regulations, and policies.	Qualitative – Description
Environmental Effects	EQ	Effects to aquatic (stream, wetland) and terrestrial (riparian, upland) habitats, water quality, and threatened/endangered species	Qualitative – Low, medium, high based on footprint of each alternative.

Table 4–2 outlines the screening criteria used to assess each management measure assessed during phase 2 of measure screening. Metrics, and their corresponding descriptions, used to assess each criterion are provided in the table. The associated account (NED = National Economic Development; RED = Regional Economic Development; OSE = Other Social Effects; EQ = Environmental Quality; NA = Not Applicable) is also provided for each criterion. Screening results for all measures are provided in the Management Measure Tracker, included in this appendix as Attachment A. Thirty measures were retained and incorporated into the formulation of alternative plans.

6. Initial Array of Alternatives

The “cornerstone” (first-added) formulation strategy was utilized to develop an initial array of alternatives that each focused on reducing flood risk via different combinations of retained measures. For each alternative, one or more measures were first identified as the cornerstone—or the single most important measure(s). Additional measures were then added to meet objectives not served by the cornerstone. A summary of the initial array of alternatives is provided in Table 5–1, below. Incorporation of each measure within each alternative for the

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

initial array (C = cornerstone; Y = yes) and measure type (S = structural; NS = nonstructural; NNB = natural and natures based; NA = not applicable) are also provided.

Table 6–1: Measures Utilized in the Initial Array of Alternatives

	Inclusion in at Least 1 Iteration of Plan Formulation										
Name	0	1	2A	2B	2C	3	4	5	6	Description	Type
Ala Wai Canal Floodwall		Y	Y	C	Y	Y	Y	C		Floodwall system along the Ala Wai Canal that may extend up the Manoa-Palolo Canal and Makiki.	S
Ala Wai Canal Tunnel (2nd Outlet)				Y						Eastern end of canal will be extended via subsurface tunnel as a second outlet to the ocean.	S
Ala Wai Golf Course Detention		C				Y	Y	Y		Design the Ala Wai Golf Course to include berm features for increased storage near the canal.	S
Daylight Ala Wai Canal (2nd Outlet)					C					Eastern end of canal will be extended via daylighting as a second outlet to the ocean.	S
Dredge Ala Wai Canal			Y	Y				Y		Ala Wai Canal will be dredged to its design depth or acceptable level of dredging, considering environmental impacts, stability, and structural integrity.	S
Dredge Manoa-Palolo Canal			Y	Y			Y			Dredge Manoa-Palolo Canal to increase storage and conveyance from Palolo and Manoa.	S
Kaimuki High School Berm / Floodwall		Y					Y			Extension of the Ala Wai Canal floodwall adjacent to/in the playing fields of the Kaimuki High School.	S
Kanaha Floodwall		Y	Y	C	Y		Y	Y		Floodwall on the Kanaha Stream where water jumps bank and flows towards Ala Moana.	S
Kapiolani Park Detention Basin		Y								Divert water to Kapiolani Park for additional flood storage.	S
Koali Road Floodwall		Y	Y	C	Y		Y	Y		Floodwall along the Manoa and Palolo Streams along Koali Rd, downstream of Kanewai Park.	S
Makiki District Park Detention		C		Y	Y		Y	Y		Makiki District Park multi-purpose detention pond.	S
Makiki Tunnel						C				Subsurface tunnel diverting water from the headwaters of the Makiki Stream to the harbor/ocean.	S
Manoa Valley District Park Detention		C	Y				Y	C		Manoa Valley District Park multi-purpose detention pond.	S
Waikiki Bypass			C	Y						Utilize existing storm sewer system or add bypasses from the Ala Wai Canal to the ocean.	S
Paki Ave Bypass			C							Utilize existing storm sewer system along Paki Ave as a bypass for Ala Wai Canal waters.	S
Palolo Channel Modification			Y				Y	Y		Deepen or widen channel to provide more within-bank storage.	S
Palolo Culverts			C							Bypass from Palolo Stream along Kapahulu Ave to Waikiki Wall outfall by upgrading existing storm sewer infrastructure.	S

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

	Inclusion in at Least 1 Iteration of Plan Formulation										
Name	0	1	2A	2B	2C	3	4	5	6	Description	Type
Palolo Valley District Park Detention		Y					Y			Palolo Valley District Park multi-purpose detention pond.	S
Piikoi Street Bypass			C			Y	Y	Y		Bypass from Kanaha Stream down Piikoi Street to Ala Moana Park by upgrading/utilizing existing storm sewer infrastructure.	S
Pumps/other structures		Y	Y	Y	Y	Y	Y	Y		Pumps and other structures, such as flap gates, to mitigate interior drainage impacts of other measures.	S
SWIFT Tunnel (Manoa)						C				Subsurface tunnel diverting water from the headwaters of the Manoa Stream to the harbor/ocean.	S
SWIFT Tunnel (Palolo)						C				Subsurface tunnel diverting water from the headwaters of the Palolo Stream to the harbor/ocean.	S
Woodlawn Drive Floodwall		Y	Y	C	Y	Y	Y	Y		Floodwall along Manoa Stream at Woodlawn Drive bridge.	S
Woodlawn Bridge Modification		Y								Modify the bridge at Woodlawn Drive to increase conveyance.	S
Woodlawn Channel Modification		Y			Y		Y	Y		Channel modification along Manoa Stream near Woodlawn Drive bridge.	S
Woodlawn Drive Bypass		Y	C	Y			Y	C		Bypass of Manoa Stream at Woodlawn Drive by constructing new inlet and upgrading/utilizing existing storm water infrastructure.	S
Nonstructural Measures		Y	Y	Y	Y	Y	Y	Y	Y	Physical (e.g., acquisition and relocation, floodproofing, and elevation) and nonphysical (e.g., flood warning system, risk communication, education, and planning) measures.	NS
Watershed Management							C			Removing invasive species and replanting with native species; controlling ungulates to reduce destruction of vegetation; and reducing impervious surfaces.	NNB
Daylight Makiki Stream		Y	Y				Y			Increasing conveyance and reducing restrictions along Makiki Stream by daylighting.	NNB
No Action	Y									No federal action.	NA

Table 5–2 provides descriptions for each alternative that was formulated for the Initial Array of Alternatives. Measure types are included in the table (S=structural; NS=nonstructural; NNB=natural and natures based; NA=not applicable) and number of iterations undergone prior to the alternative being retained or screened are also provided. Each alternative underwent multiple iterations to improve plan performance and maximize efficiency and benefits prior to either being retained or screened from further consideration. Evaluation criteria utilized during each formulation iteration are summarized below. A detailed description of the formulation and evaluation of each alternative is provided in the Plan Formulation Tracker, including in this appendix as Attachment B.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Table 6–2: Description of Initial Array of Alternatives

Alt.	Description	Type	Iterations	Retained
0	No action alternative.	NA	NA	Y
1	Storage Cornerstone – Reduces flood risk by increasing storage.	S	4	Y
2A	Conveyance (Existing Infrastructure) Cornerstone – Reduces flood risk by increasing conveyance using existing infrastructure.	S	2	N
2B	Conveyance (Floodwalls) Cornerstone – Reduces flood risk by increasing conveyance using floodwalls at various locations.	S	3	Y
2C	Conveyance (2nd Outlet) Cornerstone – Reduces flood by increasing conveyance via a second Ala Wai Canal outlet.	S	4	N
3	Tunnel Cornerstone – Reduces flood risk by implementing subsurface tunnels.	S	6	N
4	Natural and Nature-Based Cornerstone – Reduces flood risk through natural and nature-based features.	NNB	4	N
5	Hybrid Cornerstone – Reduces flood risk by combining cornerstones of other plans.	S	4	Y
6	Nonstructural Cornerstone – Reduces flood risk through nonstructural implementation.	NS	4	Y

The decision to screen or retain each alternative was determined through a set of evaluation criteria that was utilized throughout all iterations of the plan formulation process. Descriptions of and metrics used to assess each criterion are provided. The associated account (NED = National Economic Development; RED = Regional Economic Development; OSE = Other Social Effects; EQ = Environmental Quality; NA = Not Applicable) is also provided for each criterion.

Table 6–3: Alternative Evaluation Criteria

Criteria	Account	Description	Metric(s)
Efficiency	NED	Cost effectiveness—comparison of economic benefits and project costs.	Semi-quantitative – comparison of preliminary costs and expected benefits
Effectiveness (Damages Reduced)	NED	Damages to buildings, related contents, and vehicles.	Semi-quantitative – expected benefits based on previous study iterations
Effectiveness (Commerce / Tourism)	NED, RED	Degree to which flood risk is reduced in commercialized reaches and reaches frequented by tourists.	Qualitative – expected benefits in targeted reaches
Effectiveness (Life Safety)	OSE	Changes in life safety risk expected with alternative implementation.	Qualitative – expected benefits based anticipated water surface elevation reductions.
Acceptability	OSE	Workability and viability with respect to acceptance by State and local entities and the public and compatibility with existing laws, regulations, and policies.	Qualitative – Description
Environmental Effects	EQ	Effects to aquatic (stream, wetland) and terrestrial (riparian, upland) habitats, water quality, and threatened and endangered species	Qualitative – Low, medium, high based on footprint of each alternative.
Completeness	NA	Extent to which each plan provides and accounts for all necessary investments or other actions to ensure the realization of the planned effects.	Qualitative – Description

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

A summary of screening results for the final iteration of each alternative are provided in Table 5–4, below. Only the results associated with the final iteration are presented. Green indicates a positive determination for each criterion; amber indicates a neutral determination or a metric that would require further quantitative evaluation; and red indicates a negative determination.

Table 6–4: Evaluation Results for the Initial Array of Alternatives

Alt.	Effic.	Effect. (Damages)	Effect. (Lif. Saf.)	Effect. (Comm./Tour.	Accept.	Env.	Comp.
0	No	No	No	No	No	No	Positive

2A	Negative	Negative	Negative	Negative	No	No	Positive
2B	Positive	Positive	Positive	Positive	No	No	Positive
2C	Negative	No	No	Negative	No	Negative	Positive
3	Negative	No	No	No	No	Negative	Positive
4	Negative	Negative	Negative	Negative	Positive	Positive	Positive
5	Positive	Positive	Positive	Positive	No	No	Positive
6	Positive	Positive	No	Positive	No	Positive	Positive

Alternative 0. No Action Plan. USACE planning policy (Engineering Regulation 1105-2-100) and the National Environmental Policy Act (NEPA) require consideration of 'No Action'. The No Action assumes no measures would be implemented by the federal government to achieve the planning objectives. Any activities to be pursued by local, state, and/or other federal agencies are assumed to be undertaken.

Alternative 1. Storage Cornerstone. Based on the benefits calculations provided by previous studies, the storage cornerstone is likely to have positive net benefits. It is also expected to be effective at providing flood risk reduction benefits associated with all 3 study objectives—damage reduction, life safety risk reduction, and reduced impacts to commerce and tourism—throughout the watershed. Alternative 1 would also have minimal impacts to aquatic and terrestrial habitats, as well as some benefit to water quality through increased infiltration. Benefits to socially vulnerable populations in the lower portion of the watershed would likely still experience risks due to flooding along the Ala Wai Canal. Alternative 1 would be compatible with laws, regulations, and policies; however, use of public parks as detention facilities could reduce acceptability by the public.

Alternative 2A. Conveyance (Existing Infrastructure) Cornerstone. Cornerstone measures included in Alternative 2A, including the Piikoi, Woodlawn Drive, Waikiki, and Paki Avenue Bypasses, and the Palolo Culverts, were found to be largely ineffective at reducing water surface elevations and were screened out during various iterations of the plan formulation process. As a result, Alternative 2A was screened from further consideration.

Alternative 2B. Conveyance (Floodwalls) Cornerstone. Based on the benefits calculations provided by previous studies, the storage cornerstone is likely to have positive net benefits. It is also expected to be effective at providing flood risk reduction benefits associated with all 3 study objectives—damage reduction, life safety risk reduction, and reduced impacts to commerce and tourism—throughout the watershed. Alternative 2B would have some impact to riparian and marine habitats, including increasing the rate at which contaminants reach the ocean.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Alternative 2B would be compatible with laws, regulations, and policies; however, extensive floodwalls along the Ala Wai Canal could reduce acceptability by the public.

Alternative 2C. Conveyance (2nd Outlet) Cornerstone. Based on the benefits calculations provided by previous studies and preliminary costs, it was determined that the Ala Wai Canal 2nd Outlet would not have positive net benefits. Through coordination with partnering resource agencies, it was also determined that a 2nd canal outlet would also have significant environmental effects on marine resources and would also impact the tourism industry through impacted water quality along Waikiki Beach. As a result, Alternative 2C was screened from further consideration.

Alternative 3. Tunnel Cornerstone. Modeling results and preliminary cost estimates indicate that the water surface elevation reductions and associated benefits would not be sufficient to offset the costs of tunnel construction. Through coordination with partnering resource agencies, it was also determined that a 2nd canal outlet would also have significant environmental effects on marine resources. As a result, Alternative 3 was screened from further consideration.

Alternative 4. Natural and Nature-Based Cornerstone. Sensitive analysis and modeling results quantifying the potential benefits associated with watershed management activities, including reforestation, invasive management, and reducing imperviousness, indicate that these activities would not be effective at modifying hydrology and hydraulics at events larger than the 50% annual exceedance probability event. Thus, the cornerstone measures for Alternative 4 would be ineffective at reducing risk during the events that drive risk throughout the watershed. As a result, Alternative 4 was screened from further consideration.

Alternative 5. Hybrid Cornerstone. Based on the benefits calculations provided by previous studies and preliminary costs, Alternative 5 is likely to have positive net benefits. It is also expected to be effective at providing flood risk reduction benefits associated with all 3 study objectives—damage reduction, life safety risk reduction, and reduced impacts to commerce and tourism—throughout the watershed. Alternative 5 would have some impact to riparian and marine habitats, including increasing the rate at which contaminants reach the ocean; however, increasing storage and infiltration may work to reduce impacts to water quality. Alternative 5 would be compatible with laws, regulations, and policies; however, use of public parks as detention facilities and extensive floodwalls along the Ala Wai Canal could reduce acceptability by the public.

Alternative 6. Nonstructural Cornerstone. Based on the benefits calculations provided by previous studies and preliminary costs, it was determined that nonstructural measures would have positive net benefits in many portions of the watershed. It is also expected to be effective at providing flood risk reduction benefits associated with all 3 study objectives—damage reduction, life safety risk reduction, and reduced impacts to commerce and tourism—throughout the watershed. However, lower participation rates could render this alternative incomplete and impact overall efficiency. Alternative 6 would have minimal impact on environmental resources.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

7. Final Array of Alternatives

The final array consisted of 5 alternatives, as outlined below.

Alternative 0. No Action: USACE planning policy (Engineering Regulation 1105-2-100) and the National Environmental Policy Act (NEPA) require consideration of 'No Action'. The No Action assumes no measures would be implemented by the federal government to achieve the planning objectives. Any activities to be pursued by local, state, and/or other federal agencies are assumed to be undertaken.

Alternative 1. Storage Cornerstone: Alternative 1 primarily focuses on increasing storage throughout the Ala Wai watershed to reduce flood risk. Implementation of this alternative would include the construction of several detention basins and floodwalls in strategic locations.

Makiki District Park Detention Basin & Kanaha Floodwall–At Makiki District Park, in Makiki Valley, a detention basin (i.e., Makiki District Park Detention Basin) would be constructed to temporarily store stormwater runoff. The detention basin would be constructed by excavating down approximately 6 to 10 ft and constructing a 6-foot-high floodwall with earthen slopes around the perimeter of the park (~1,200 ft in length). The Makiki District Park Detention Basin would have a storage volume of approximately 22 acre-feet. A floodwall extending 6 ft above ground level would be constructed along the right descending bank of the Kanaha Ditch (i.e., Kanaha Floodwall). The floodwall would be approximately 2,200 ft long, with five road closure structures. The Makiki District Park Detention Basin and Kanaha Floodwall function as a system, with the floodwall helping to move water efficiently and effectively from the Kanaha Ditch into the Makiki District Detention Basin, reducing the risk of flooding for adjacent and downstream communities.

Manoa Valley District Park Detention Basin–At Manoa Valley District Park, in Manoa Valley, a detention basin (i.e., Manoa Valley District Park Detention Basin) would be constructed to temporarily store stormwater. The detention basin would be constructed by excavating down approximately 6 to 8 ft and constructing a 6-foot-high around the perimeter of the park (~1,580 ft in length). The Manoa Valley District Park Detention Basin would have a storage volume of approximately 54 acre-feet. The purpose of the Manoa Valley District Park Detention Basin is to reduce the risk of flooding to residential structures downstream of the park.

Woodlawn Drive Floodwall & Koali Road Floodwall–Also within Manoa Valley, a floodwall extending 6 ft above ground level (i.e., Woodlawn Drive Floodwall) would be constructed along the right descending bank of Manoa Stream. The floodwall would be approximately 1,625 ft in length. A single road closure structure at Woodlawn Drive would be constructed. The Woodlawn Drive Floodwall would reduce the risk of flooding to the University of Hawaii and downstream residential structures due to overtopping at Woodlawn Drive Bridge. At Koali Road, near the convergence of Manoa and Palolo streams, a floodwall extending 6 ft above ground (i.e., Koali Road floodwall) would be constructed along the left descending bank of Manoa Stream and the right descending bank of Palolo Stream. The floodwall would be approximately 2,485 ft in length. Two box culverts would be constructed to provide interior drainage of stormwater flows from the residential neighborhood behind the Koali Road floodwall. Two road closure structures would be constructed. The purpose of the Koali Road Floodwall is to reduce risk to adjacent

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

residential structures, including induced damages caused by the Woodlawn Drive Floodwall. Thus, the Woodlawn Drive Floodwall and Koali Road Floodwall function as a system.

Kaimuki High School Floodwall–At Kaimuki High School, adjacent to the Manoa-Palolo Canal, a floodwall extending 6 ft above ground (i.e., Kaimuki High School Floodwall) would be constructed along the left descending bank of Manoa-Palolo Canal. The floodwall would be approximately 4,400 ft long. The Kaimuki High School floodwall would extend around the perimeter of Kaimuki High School's athletic fields. Two road closure structures would be constructed. The floodwall would be to reduce the risk of flooding to communities east/southeast of Kaimuki High School.

Ala Wai Golf Course Detention Basin–An earthen levee approximately 6 ft in height would be constructed around the perimeter of Ala Wai Golf Course to create a detention basin (i.e., Ala Wai Golf Course Detention Basin). The total length of the earthen levee would be approximately 10,665 ft in length. The golf course detention basin would have a storage volume of approximately 314 acre-feet. A concrete in-stream weir diversion structure would be constructed approximately 50 feet downstream of the Date Street Bridge, allowing stormwater to enter the golf course detention basin starting at the 20-year storm event. Three concrete drainage structures with flap gates would be constructed along the southwest side of the Ala Wai Golf Course to allow collected stormwater to slowly drain into the Ala Wai Canal. Three road closure structures would be constructed. The Ala Wai Golf Course Detention Basin would reduce the risk of flooding within the lower watershed.

Nonstructural Measures–Physical nonstructural measures, including structure elevation, floodproofing, and acquisition and relocation, were considered in relevant reaches to reduce residual risk not addressed by structural measures. Nonphysical measures, including risk communication, were also considered for incorporation.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

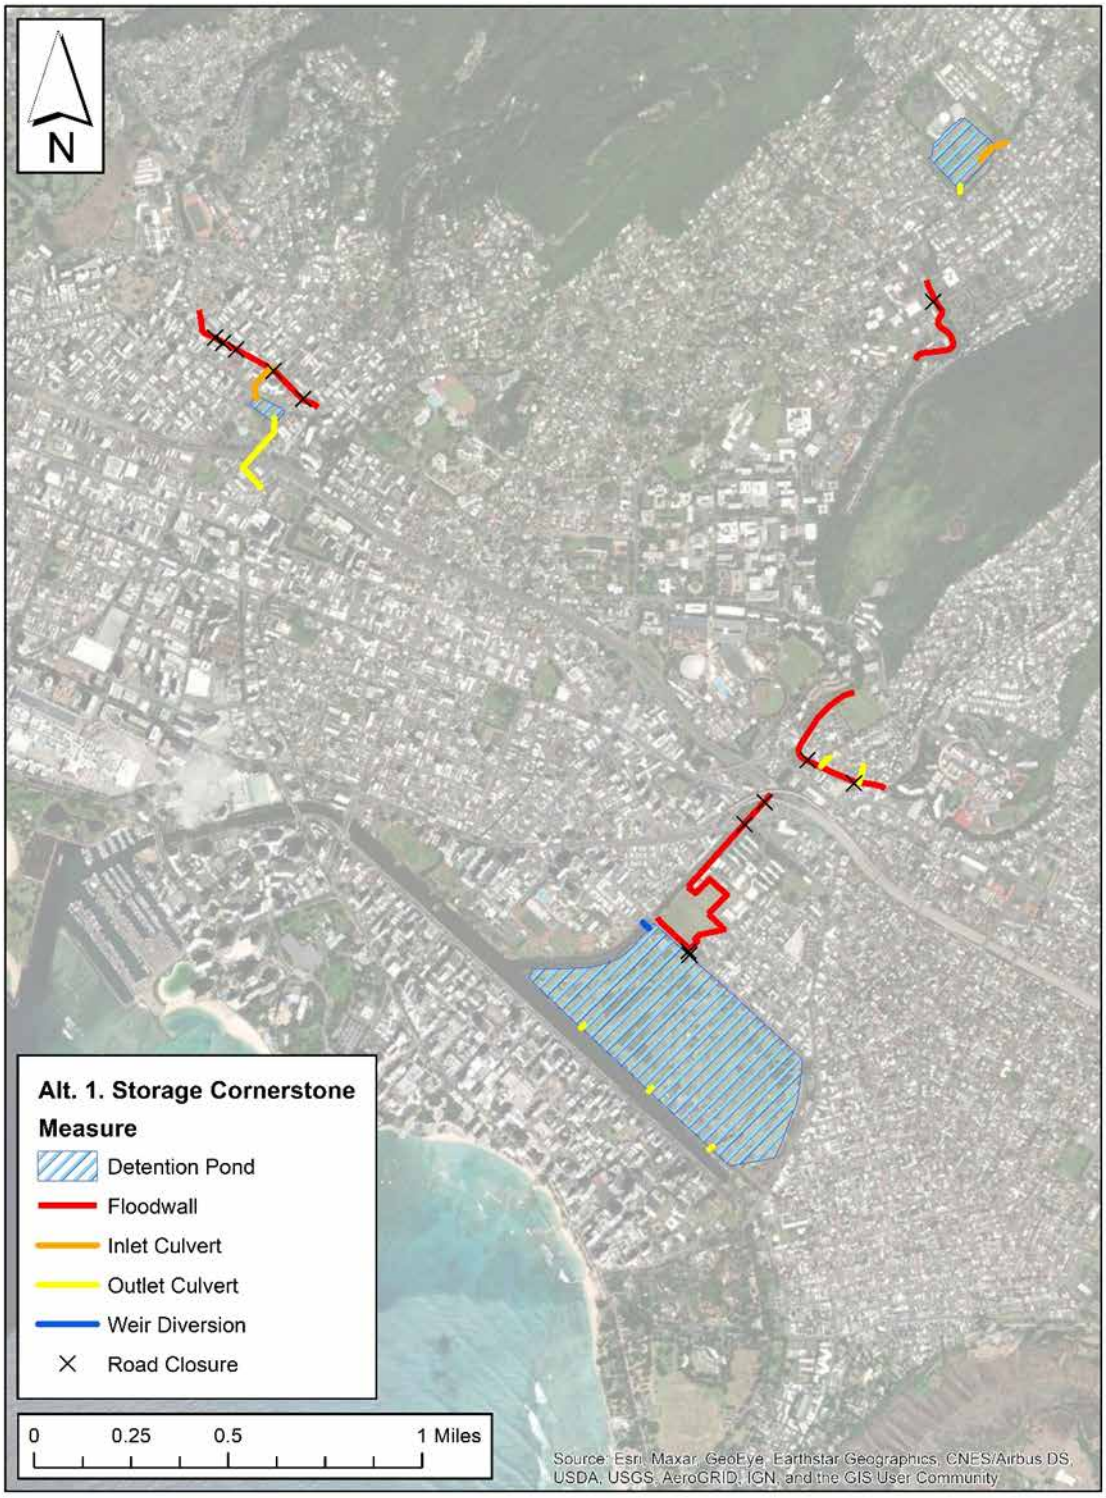

Figure 7-1: Conceptual Diagram of Alternative 1

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Alternative 2B. Conveyance (Floodwalls) Cornerstone: Alternative 2B includes the Makiki District Park Detention Basin, Kanaha Floodwall, Woodlawn Drive Floodwall, Koali Road Floodwall, and Nonstructural Measures as described above under Alternative 1.

Ala Wai Canal Floodwall and Kaimuki High School Floodwall–Along the Ala Wai Golf Course, Manoa-Palolo Canal, and Ala Wai Canal, a floodwall extending 6 ft above ground (i.e., Ala Wai Canal Floodwall) would be constructed. The floodwall would be approximately 24,745 ft long. Six existing stormwater sewers inletting into the Ala Wal Canal would be modified to include a flap gate. Nine road closure structures would be constructed. The purpose of the Ala Wai Canal Floodwall would be to reduce the risk of flooding within the McCully-Moiliili neighborhood, Diamond Head neighborhood, and Waikiki. At Kaimuki High School, adjacent to the Manoa-Palolo Canal, a floodwall extending 6 ft above ground (i.e., Kaimuki High School Floodwall) would be constructed along the left descending bank of Manoa Manoa-Palolo Canal. The floodwall alignment is different from the alignment in Alternative 1. Under Alternative 2B, the Kaimuki High School Floodwall would be approximately 3,660 ft long, extending around the perimeter of Kaimuki High School's athletic fields and joining the Ala Wai Canal Floodwall near Date Street as discussed below. The Kaimuki High School Floodwall would reduce flood risk within communities east/southeast of Kaimuki High School. The Ala Wai Canal and Kaimuki High School Floodwalls would function as a single system.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

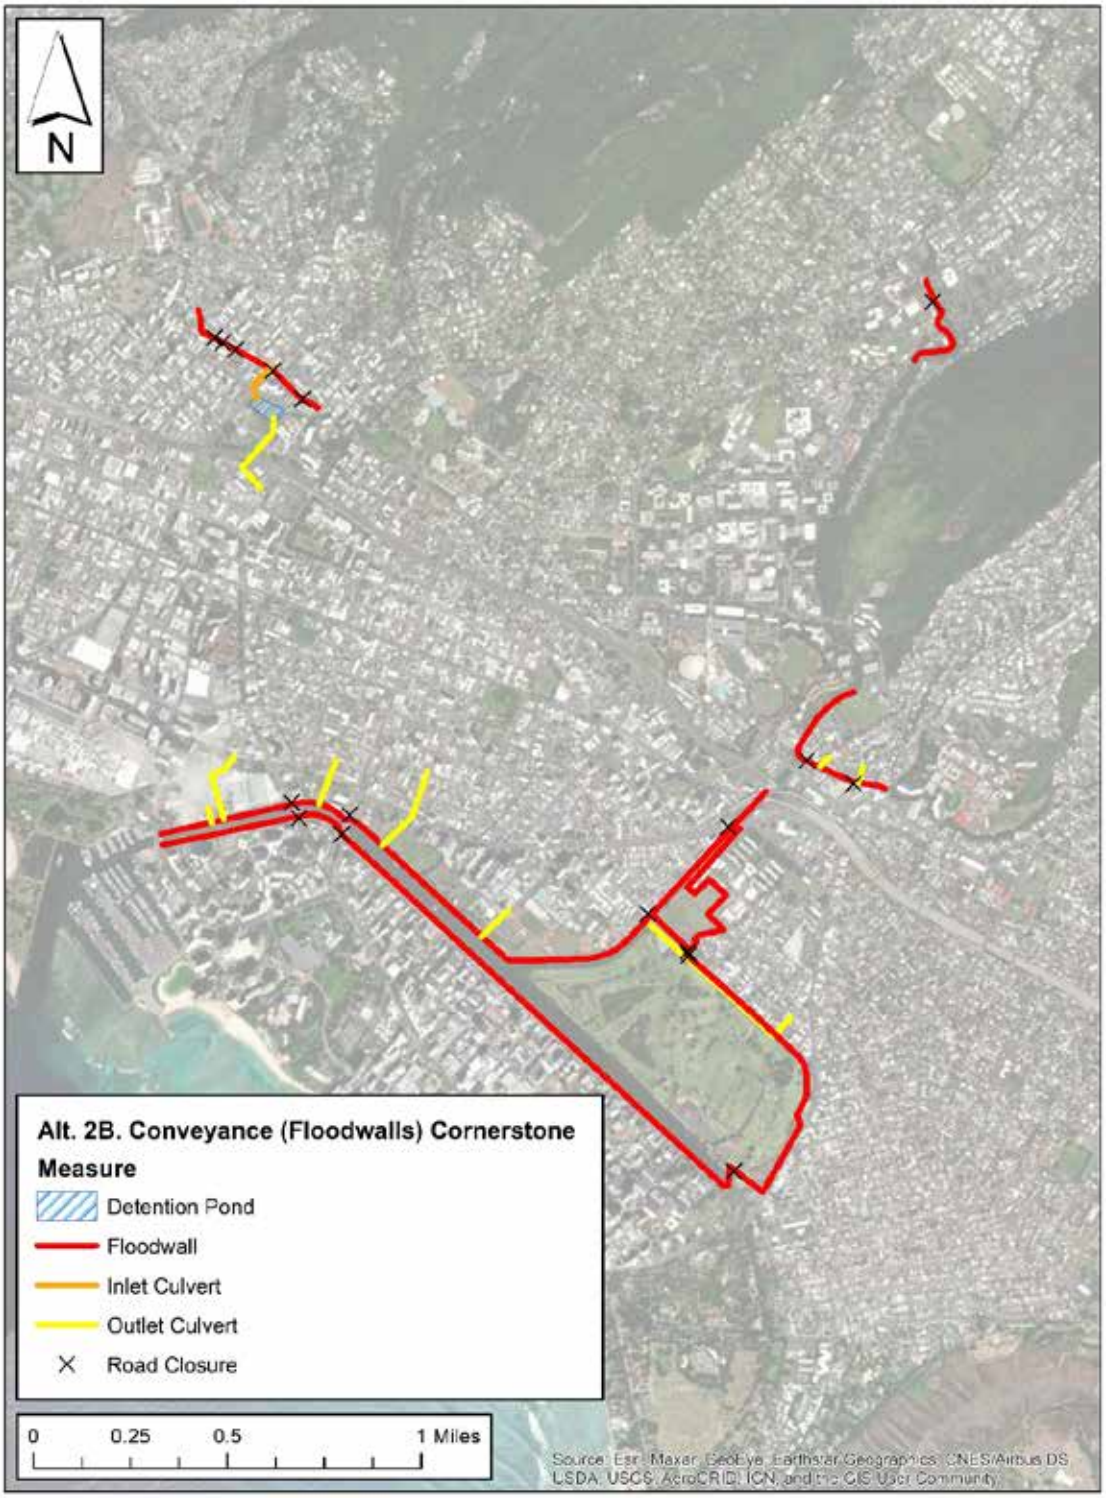

Figure 7-2: Conceptual Diagram of Alternative 2B

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Alternative 5. Hybrid Cornerstone: Alternative 5 includes the Makiki District Park Detention Basin, Kanaha Floodwall, Manoa Valley District Park Detention Basin, Woodlawn Drive Floodwall, Koali Road Floodwall, and Nonstructural measures as described under Alternative 1.

Ala Wai Golf Course Detention Basin–At Ala Wai Golf Course, adjacent to the Manoa-Palolo Canal and the Ala Wai Canal, an earthen levee approximately 6 ft in height would be constructed around the perimeter of Ala Wai Golf Course to create a detention basin (i.e., Ala Wai Golf Course Detention Basin). The total length of the earthen levee would be approximately 5,640ft in length and would extend along the perimeter of the Ala Wai Golf Course along the Manoa-Palolo and Ala Wai canals. Near the vicinity of the Kapahulu Avenue and Ala Wai Boulevard intersection, the levee would join with the Ala Wai Canal Floodwall on the left descending bank of Ala Wai Canal. The existing drainage ditch that runs along the north side of the golf course (parallel to Date Street) would be riprapped and used as an inlet for stormwater to overflow into the Ala Wai Golf Course Detention Basin. Three concrete drainage structures with flap gates would be constructed along the southwest side of the Ala Wai Golf Course to allow collected stormwater to slowly drain into Ala Wai Canal. The Ala Wai Golf Course Detention Basin would reduce the risk of flooding within the lower watershed.

Ala Wai Canal Floodwall & Kaimuki High School Floodwall– At the Manoa-Palolo Canal and Ala Wai Canal, a floodwall extending 6 ft above ground (i.e., Ala Wai Canal Floodwall) would be constructed. The floodwall would be approximately 24,140 ft long. Fourteen existing stormwater sewers inletting into the Ala Wai Canal would be modified to include a flap gates. Twelve road closure structures would be constructed. The purpose of the Ala Wai Canal Floodwall would be to reduce the risk of flooding within the McCully-Moiliili neighborhood, Diamond Head neighborhood, and Waikiki. At Kaimuki High School, adjacent to the Manoa-Palolo Canal, a floodwall extending 6 ft above ground (i.e., Kaimuki High School Floodwall) would be constructed along the left descending bank of Manoa Manoa-Palolo Canal. The floodwall alignment is different from the alignment in Alternatives 1 and 2B. Under Alternative 5, the Kaimuki High School Floodwall would be approximately 3,260 ft long, cutting between the athletic fields and joining the Ala Wai Canal Floodwall near Date Street. The Kaimuki High School Floodwall would reduce flood risk within communities east/southeast of Kaimuki High School. The Ala Wai Canal and Kaimuki High School Floodwalls would function as a system.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

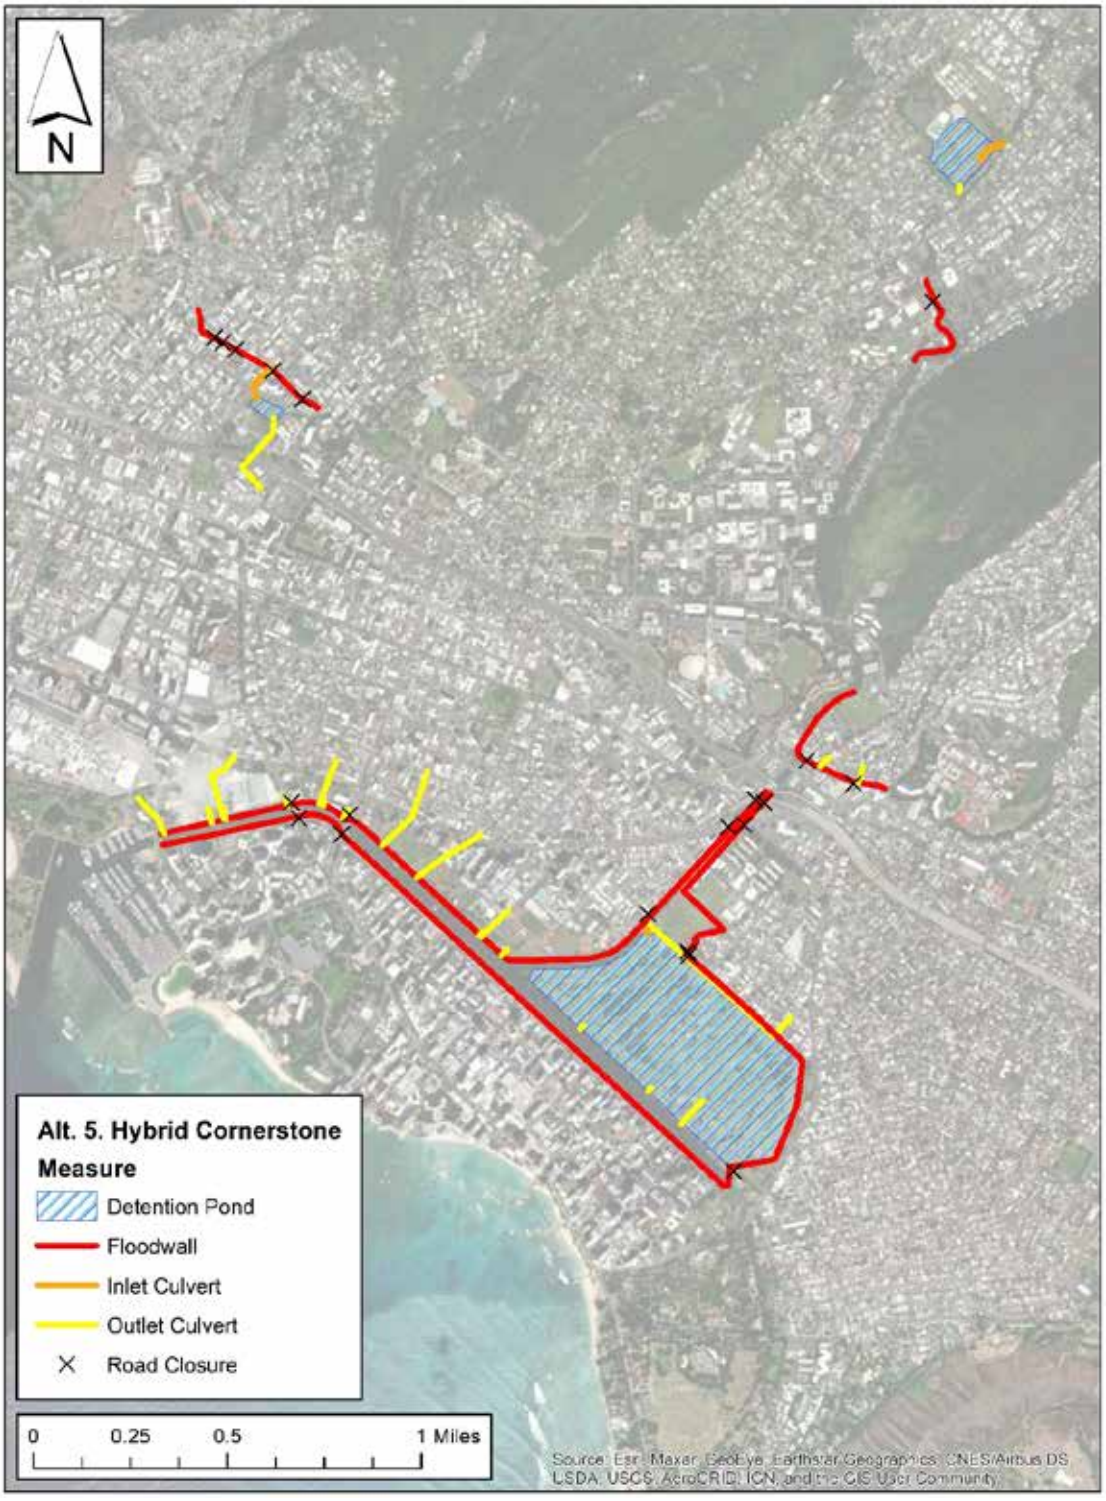

Figure 7-3: Conceptual Diagram of Alternative 5

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Alternative 6. Nonstructural Cornerstone: Alternative 6 consists of floodproofing and elevation of a total of 1,544 structures—43 elevations and 1501 with dry floodproofing—within 3 separate reaches with positive NED benefits. Structures within the 1% AEP floodplain in reaches AW1 (953) and AW2R (542) would be elevated or floodproofed to the 1% AEP flood stage (see Figure 7-4 for location of each reach). Structures within the 2% AEP floodplain in reach AW7R (49) would be elevated or floodproofed to the 2% AEP event. The target stage for all reaches is the 1% AEP event.

Figure 7-4: Targeted Reaches for Nonstructural Measures

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

8. Comparison of the Final Array of Alternatives

A summary of the comparison of the final array of alternatives is presented below in

Table 8–1: Summary of Comparison of the Final Array of Alternatives

Consideration	Alt. 0. No Action	Alt. 1. Storage Plan	Alt. 2B. Conveyance Plan	Alt. 5. Hybrid Plan	Alt. 6. Nonstructural Plan
1. Account Analysis					
A. National Economic Development (NED)					
(1) Average Annual Net Benefits	$0	$26,835,000	$43,464,000	$52,303,000	$32,367,000
(2) BCR	0	3.0	2.1	2.7	1.76
(3) Rank	5th	4th	2nd	1st	3rd
B. Regional Economic Development (RED)					
(1) Employment	0 full-time equivalent jobs	2,197 full-time equivalent jobs	5,562 full-time equivalent jobs	8,141 full-time equivalent jobs	6,279 full-time equivalent jobs
(2) Labor Income	$0	$161,392,000	$408,582,000	$608,967,000	$447,000,000
(3) Rank	5th	4th	2nd	1st	3rd
C. Other Social Effects					
(1) Life Safety	0 expected annual life loss reduction	0.092 expected annual life loss induction	0.180 expected annual life loss induction	0.003 expected annual life loss reduction	0 expected annual life loss reduction
(2) Social Vulnerability	No additional impacts to socially vulnerable communities	Medium benefit to socially vulnerably communities	Largest increase in risk to socially vulnerable communities	Largest benefit to socially vulnerable communities	No significant benefit anticipated for socially vulnerable communities
(3) Rank	4th	2nd	5th	1st	3rd
D. Environmental Quality					
(1) Environmental Impacts	No additional impact to environmental resources	Minimally impactful to environmental resources	Most impactful to environmental resources	Minimally impactful to environmental resources	Least impactful to environmental resources
(2) Rank	2nd	3rd (tie)	4th	3rd (tie)	1st
2. Alternative Evaluation					
A. Criteria					
(1) Efficiency	No net economic benefits. Rank = 5th	$17,743,000 in net benefits. Rank = 3rd	$23,195,000 in net benefits. Rank = 2nd	$33,104,000 in net benefits. Rank = 1st	$14,023,000 in net benefits. Rank = 4th

(2) Effectiveness (Damage)	No damages reduced. Rank = 5th	$26,835,000 in damages reduced. Rank = 4th	$43,464,000 in damages reduced. Rank = 2nd	$52,303,000 in damages reduced. Rank = 1st	$32,367,000 in damages reduced. Rank = 3rd
(3) Effectiveness (Life Safety)	No reduction in life safety risk. Rank = 2nd (tie)	0.180 increase in expected annual life safety risk. Rank = 4th	0.092 increase in expected annual life safety risk. Rank = 3rd	0.003 reduction in expected annual life safety risk. Rank = 1st	No significant change in life safety risk. Rank = 2nd (tie)
(4) Acceptability	Meets acceptability criteria. Rank=1st (tie).	Meets acceptability criteria. Rank=1st (tie).	Meets acceptability criteria. Rank=1st (tie).	Meets acceptability criteria. Rank=1st (tie).	Meets acceptability criteria. Rank=1st (tie).
(5) Completeness	Meets completeness criteria. Rank=1st (tie).	Meets completeness criteria. Rank=1st (tie).	Meets completeness criteria. Rank=1st (tie).	Meets completeness criteria. Rank=1st (tie).	Meets completeness criteria. Rank=1st (tie).
(6) Environmental Effects	No effect on environmental resources. Rank = 1st.	No significant effects on environmental resources. Rank =2nd (tie).	No significant effects on environmental resources. Rank =2nd (tie).	No significant effects on environmental resources. Rank =2nd (tie).	No significant effects on environmental resources. Rank =2nd (tie).
(7) Rank	5th	4th	2nd	1st	3rd
B. *Contribution to Objectives*					
(1) Life Safety	No benefits to life safety. Rank = 2nd (tie).	Highest induced life safety risk. Rank = 4th.	Induced life safety risk. Rank = 3rd.	Largest reduction in life safety risk. Rank = 1st.	No benefits to life safety risk. Rank = 2nd (tie).
(2) Economic Damages	No reduction in economic damages. Rank = 5th.	$26,835,000 in damages reduced. Rank = 4th	$43,464,000 in damages reduced. Rank = 2nd	$52,303,000 in damages reduced. Rank = 1st	$32,367,000 in damages reduced. Rank = 3rd
(3) Reduce impacts to commerce and tourism	No reduction in disruptions to commerce and tourism. Rank = 5th.	Minor effects on Waikiki and Ala Moana. Positive effect on Manoa. Rank = 3rd.	Positive impact to Waikiki and areas along Manoa. Negative effect to Ala Moana. Rank = 2nd.	Greatest positive impact (i.e., reduced risk) in all target reaches. Rank = 1st.	Would benefit target reaches; participation may impact benefits. Rank = 4th.
(4) Rank	5th	4th	2nd	1st	3rd
C. Risk and Uncertainty					
(1) Residual Risk	No change in flood risk throughout	Fourth largest reduction in	Second largest reduction in	Largest reduction in	Third largest reduction in

	the watershed. Greatest residual risk. Rank=5th.	residual risk. Rank = 4th.	residual risk. Rank = 2nd.	residual risk. Rank = 1st.	residual risk. Rank = 3rd.
(2) Uncertainty	Relies completely on non-Federal action to reduce flood risk. Rank = 3rd.	Mitigation requirements are currently unknown. Rank = 1st (tie).	Mitigation requirements are currently unknown. Rank = 1st (tie).	Mitigation requirements are currently unknown. Rank = 1st (tie).	Participation rates could affect benefits. Rank = 2nd.
(3) Rank	5th	4th	2nd	1st	3rd

System of Accounts. Alternative 5 has the greatest net economic benefits ($33,104,000). Alternative 1 has the highest BCR (3.0). Alternative 5 is the alternative which reasonably maximizes benefits across the Four Accounts. The TSP is made up of measures, also referred to as project features, to minimize the extent of flooding within the Ala Wai watershed during frequent storm events.

Alternative Evaluation. Alternative 5 represents the most efficient plan in terms of net economic benefits, but Alternative 1 represents the most efficient plan in terms of BCR. Alternative 5 ranked the highest in terms of all three effectiveness criteria – having the greatest reduction in economic damages, the great reduction in impacts to commerce and tourism, and the great benefit to life safety. Alternative 5 appears to also be the most effective in reducing flood risk in socially vulnerable communities which, in turn, enhances community resiliency and community cohesion.

9. Tentatively Selected Plan (TSP)

Alternative 5 is the Tentatively Selected Plan (TSP). Based on the cost and benefit analysis of the final array of alternatives, the NED Plan is Alternative 5. Based on the evaluation of decision-driving metrics across the Four Accounts, Alternative 5 is also the Comprehensive Benefits Plan, as it reasonably maximizes benefits across the NED, RED, EQ, and OSE accounts.

10. Incremental Justification

The study team conducted an incremental justification analysis for measures included in Alternative 5—the NED and comprehensive benefits plan. For the purposes of this analysis, the study team considered the following as separable elements:

Table 10–1: Incremental Justification Assessment

Element/System	Analysis & Results	Determination
Makiki District Park Detention Basin and Kanaha Floodwall	Additional H&H and economic analysis indicated that the Makiki District Park Detention and Kanaha Floodwall are not separably economically justified (i.e., benefits do not outweigh the costs), do not substantially reduce life safety	Remove from Alternative 5.

	risk, and would not benefit the most socially vulnerable communities.	
Manoa District Park Detention Basin	Additional H&H and economic analysis indicated that the Manoa District Park Detention Basin is not separably economically justified, does not substantially reduce life safety risk, and would not benefit the most socially vulnerable communities.	Remove from Alternative 5
Woodlawn Drive Floodwall and Koali Road Floodwall	H&H and economic results were compared with and without the Woodlawn Drive and Koali Road Floodwall system. These results indicated that these measures are economically justified (i.e., benefits outweigh the costs) and would benefit the most socially vulnerable communities.	Retain in Alternative 5
Ala Wai Golf Course Detention Basin	Comparison of model runs with and without the Ala Wai Golf Course Detention Basin indicate that it is economically justified (i.e., benefits outweigh the cost) and that it helps reduce induced risk resulting from the other project features.	Retain in Alternative 5
Ala Wai Canal Floodwall and Kaimuki High School Floodwall	Comparison of model runs with and without the Ala Wai Canal and Kaimuki High School Floodwalls indicate these measures are separably justified (i.e., benefits outweigh the costs) and that it helps reduce risks to socially vulnerable populations.	Retain in Alternative 5

Alternative 5.1 - Modified Tentatively Selected Plan (TSP). A summary and associated map of the features included in the tentatively selected plan after completion of the incremental analysis efforts is provided below; this modification of Alternative 5 is being called Alternative 5.1.

Woodlawn Drive Floodwall & Koali Road Floodwall– Also within Manoa Valley, a floodwall extending 6 ft above ground level (i.e., Woodlawn Drive Floodwall) would be constructed along the right descending bank of Manoa Stream. The floodwall would be approximately 1,625 ft in length. A single road closure structure at Woodlawn Drive would be constructed. The Woodlawn Drive Floodwall would reduce the risk of flooding to the University of Hawaii and downstream residential structures due to overtopping at Woodlawn Drive Bridge. At Koali Road, near the convergence of Manoa and Palolo streams, a floodwall extending 6 ft above ground (i.e., Koali Road floodwall) would be constructed along the left descending bank of Manoa Stream and the right descending bank of Palolo Stream. The floodwall would be approximately 2,485 ft in length. Two box culverts would be constructed to provide interior drainage of stormwater flows from the residential neighborhood behind the Koali Road floodwall. Two road closure structures would be constructed. The purpose of the Koali Road Floodwall is to reduce risk to adjacent residential structures, including induced damages caused by the Woodlawn Drive Floodwall. Thus, the Woodlawn Drive Floodwall and Koali Road Floodwall function as a system.

Ala Wai Golf Course Detention Basin– At Ala Wai Golf Course, adjacent to the Manoa-Palolo Canal and the Ala Wai Canal, an earthen levee approximately 6 ft in height would be constructed around the perimeter of Ala Wai Golf Course to create a detention basin (i.e., Ala Wai Golf Course Detention Basin). The total length of the earthen levee would be approximately 5,640 ft in length and would extend along the perimeter of the Ala Wai Golf Course along the Manoa-Palolo and Ala Wai canals. Near the vicinity of the Kapahulu Avenue and Ala Wai Boulevard intersection, the levee would join with the Ala Wai Canal Floodwall on the left descending bank of Ala Wai Canal. The existing drainage ditch that runs along the north side of the golf course (parallel to Date Street) would be riprapped and used as an inlet for stormwater to overflow into the Ala Wai Golf Course Detention Basin. Three concrete drainage structures with flap gates would be constructed along the southwest side of the Ala Wai Golf Course to allow collected stormwater to slowly drain into Ala Wai Canal. The Ala Wai Golf Course Detention Basin would reduce the risk of flooding within the lower watershed.

Ala Wai Canal Floodwall & Kaimuki High School Floodwall– At the Manoa-Palolo Canal and Ala Wai Canal, a floodwall extending 6 ft above ground (i.e., Ala Wai Canal Floodwall) would be constructed. The floodwall would be approximately 24,140 ft long. Fourteen existing stormwater sewers inletting into the Ala Wai Canal would be modified to include a flap gates. Twelve road closure structures would be constructed. The purpose of the Ala Wai Canal Floodwall would be to reduce the risk of flooding within the McCully-Moiliili neighborhood, Diamond Head neighborhood, and Waikiki. At Kaimuki High School, adjacent to the Manoa-Palolo Canal, a floodwall extending 6 ft above ground (i.e., Kaimuki High School Floodwall) would be constructed along the left descending bank of Manoa Manoa-Palolo Canal. The floodwall alignment is different from the alignment in Alternatives 1 and 2B. Under the incrementally justified Alternative 5, or TSP, the Kaimuki High School Floodwall would be approximately 3,260 ft long, cutting between the athletic fields and joining the Ala Wai Canal Floodwall near Date Street. The Kaimuki High School Floodwall would reduce flood risk within communities east/southeast of Kaimuki High School. The Ala Wai Canal and Kaimuki High School Floodwalls would function as a system.

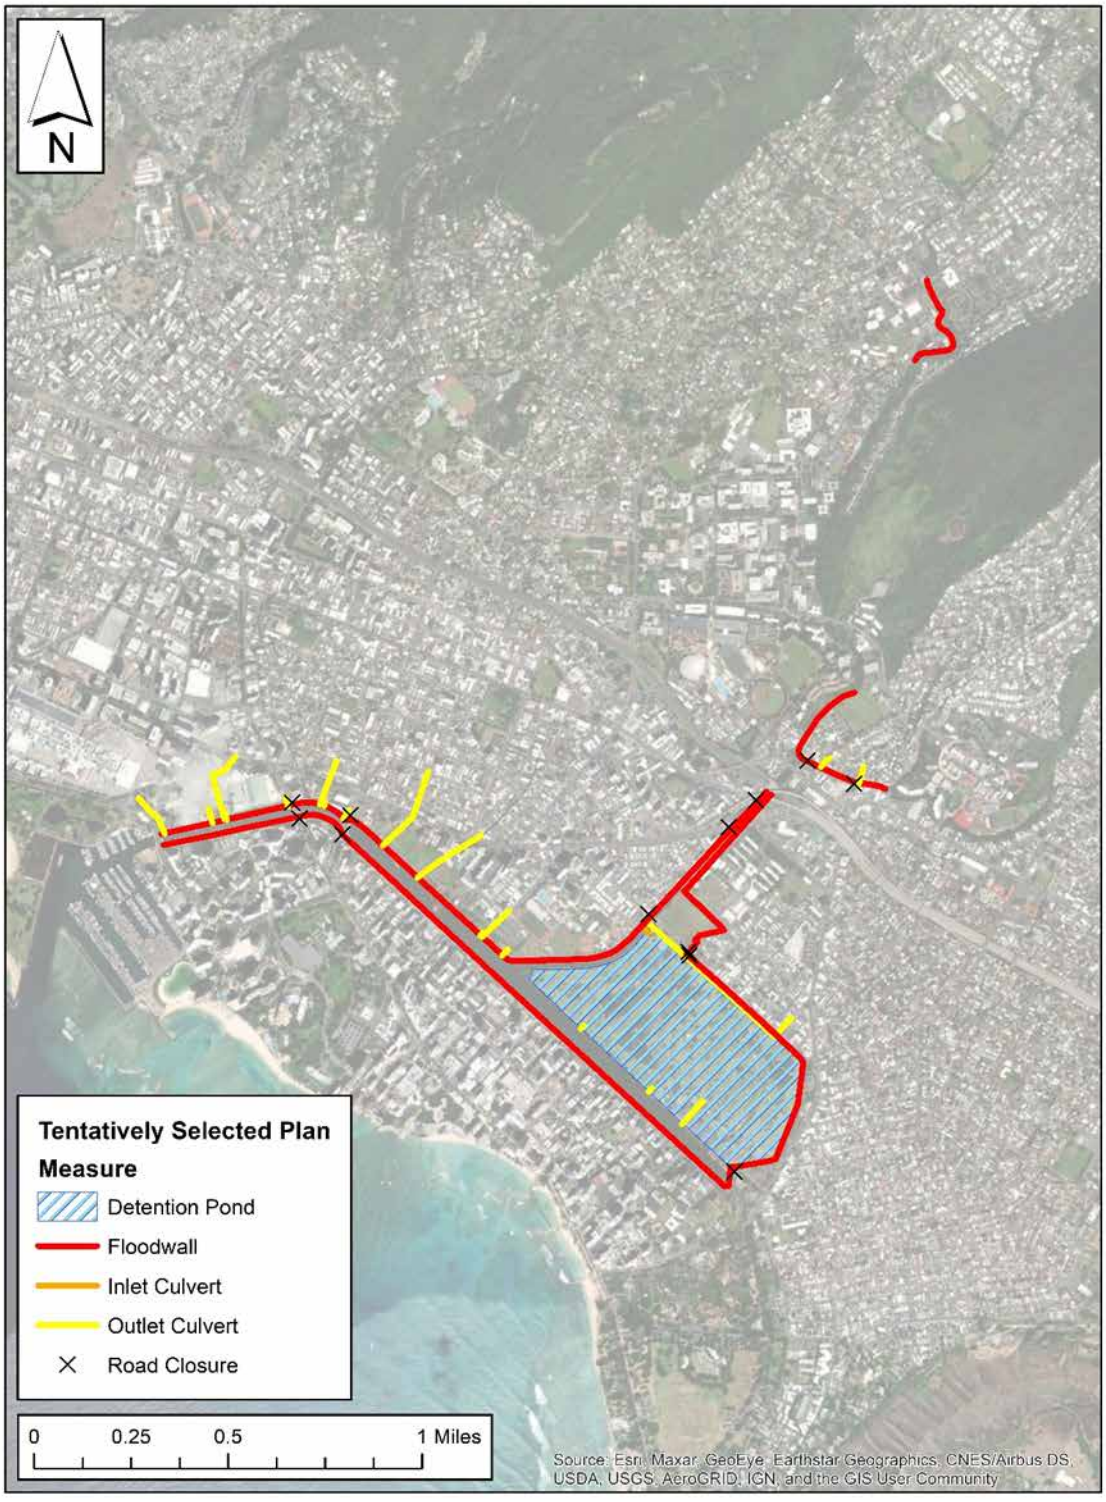

Figure 10-1: Conceptual Diagram of Alternative 5.1

11. Optimization

11.1. Overview of Optimization

The study team optimized Alternative 5.1 with a two-fold goal. First, the study team assessed whether structural features within the TSP could be modified to reduce residual risk while also capturing more project benefits and, second, the study team wanted to minimize the potential for induced flooding and induced damages to occur from implementation of the TSP. Table 11–1 summarizes the progress of Alternative 5 as it evolved through the plan formulation process. These changes were informed by extensive modeling and detailed evaluations to determine if the changes were effective in meeting the aforementioned goals.

Table 11–1: Summary of Changes to Alternative 5 (TSP)

Alternative	Measures Added/Modifications	Measures Removed
Alternative 5.1 (Incremental Analysis)	None.	Makiki District Park Detention and the Kanaha Floodwall were removed because this measure was not justified when evaluated as a separable element. Manoa Valley District Park Detention was removed because this measure was not justified when evaluated as a separable element.
Alternative 5.2 (Optimization)	Makiki Floodwalls were added to address induced flooding concerns in Lower Makiki. A ringwall around the club house at the Ala Wai Golf Course was added to address flooding concerns at the club house. Berm and floodwall alignments were adjusted on the southeastern portion of the Ala Wai Golf Course Detention to improve the performance of the system. The alignment of floodwalls near Kaimuki High School was adjusted to improve the performance of the system. An elevated walking path was added to the Ala Wai Canal Floodwalls to mitigate for negative viewshed impacts.	
Alternative 5.3 (Optimization)	Floodwall alignment adjusted at the Ala Wai Community Park to improve channel conveyance. Floodwall alignment on the Ala Wai Canal, near the golf course, was adjusted to increase channel conveyance.	Makiki Floodwalls were removed because additional analysis concluded that they were not effective in reducing potential induced damages. Ringwall at the Ala Wai Golf Course removed to increase the

	Many segments of the berm around the Ala Wai Golf Course were raised from 6 feet to 9 feet to increase total storage volume of the Ala Wai Golf Course detention feature.	storage area of the Ala Wai Golf Course detention. Wet floodproofing of the clubhouse will likely be needed.

Figure 11-1 visually displays the changes of Alternative 5.2, which led to the TSP maturing into Alternative 5.3. All substantial changes to Alternative 5.2 are displayed in red.

Figure 11-1: Conceptual Diagram of Changes to Alternative 5.2

The study team also analyzed the possibility of including physical nonstructural measures into Alternative 5, based on previous analysis which had identified reaches where nonstructural measures would likely be economically justified as standalone measures and within reaches where the study team believe residual flood risk could be reduced further through the application of nonstructural measures. Figure 10-1 provides a conceptual diagram of the reaches where nonstructural measures were considered for inclusion in the TSP; only reaches AW2R, AW2L, and AW9R were considered.

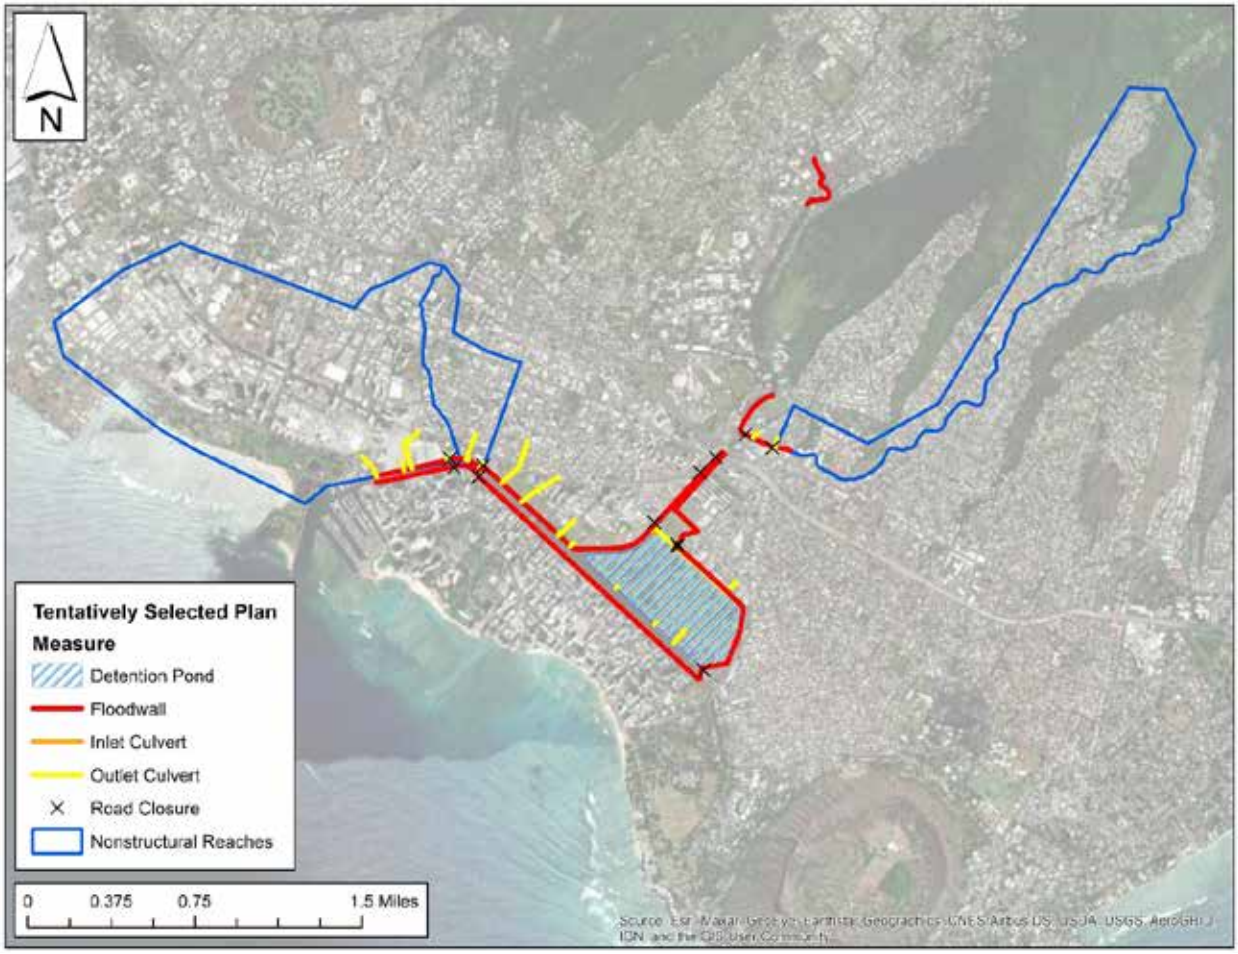

Figure 11-2: Conceptual Diagram of Nonstructural Measures for the TSP

The study team developed rough order of magnitude costs for nonstructural mitigation using existing USACE studies, including studies in American Samoa and North Carolina. Mitigation costs were developed and included for the 48 structures with mitigation measures at the 5% AEP event. Construction costs were assumed to be $500,000 per structure and included 100% contingency to address uncertainties in implementation of nonstructural measures, including mitigation action and construction costs. Utilizing these cost estimates and assumptions, construction associated with elevation and floodproofing measures for the 48 structures included for mitigation under the 5% AEP event are $48,000,000. Anticipated costs also include $2,400,000 in temporary relocations ($50,000 per structure); real estate review and administration costs $384,000 ($8,000 per structure); $8,640,000 (18%) for planning, engineering and design; and $3,360,000 in construction management (7%). Total mitigation costs for elevating and floodproofing structures under the 5% AEP event are $62,784,000.

The estimate above assumes that real estate is not compensable and impacted property owners will be offered the opportunity to voluntarily participate in non-structural mitigation measures described above. Purchasing of the real estate and relocation of the 48 structures with induced flooding at the 5% AEP flood event would cost approximately $239,000,000.

The study team acknowledges recent case law regarding what level of induced flooding constitutes a takings (i.e., requires purchase of affected properties and relocation of affected inhabitants away from the flood hazard) that may change how USACE interprets and implements policy regarding induced flooding. The study team will include those potential risks in discussions and analyses moving forward. Given this uncertainty, the study team recommends incorporating $300,000,000 in potential mitigation costs. These costs are expected to cover a combination of acquisition and relocation or elevation/floodproofing of all 70 structures with induced flooding under the 1% AEP event. Potential mitigation scenarios that could be covered by the $300,000,000 include elevation and floodproofing of all 70 structures ($91,560,000) or acquisition and relocation of all 48 structures with induced flooding under the 5% AEP and elevation/floodproofing of the remaining structures with induced flooding under the 1% AEP ($292,000,000).

11.2. Alternative 5.3 Benefit-Cost Evaluation

After the TSP was identified, the plan was optimized to reduce uncertainty in engineering modeling and real estate assumptions, and to reduce induced damages. As a result, floodwall alignments were updated in the H&H modeling, and the berm at the Ala Wai Golf Course detention basin was increased to allow for greater storage capacity, resulting in lower induced damages in Reaches 2R and 2L. The updated TSP was named Alternative 5.3. For a comprehensive summary of measures modeled in HEC-RAS for different iterations of the TSP, please see Appendix B of this report.

Alternative 5.3 is a considerable improvement from Alternative 5 in that the benefits it captures have been optimized; additionally, induced damages have been reduced, to the extent possible, through extensive adjustments to the structural measures contained in the alternative. Figure 11-2 displays a conceptual diagram of Alternative 5.3 and its optimized measures.

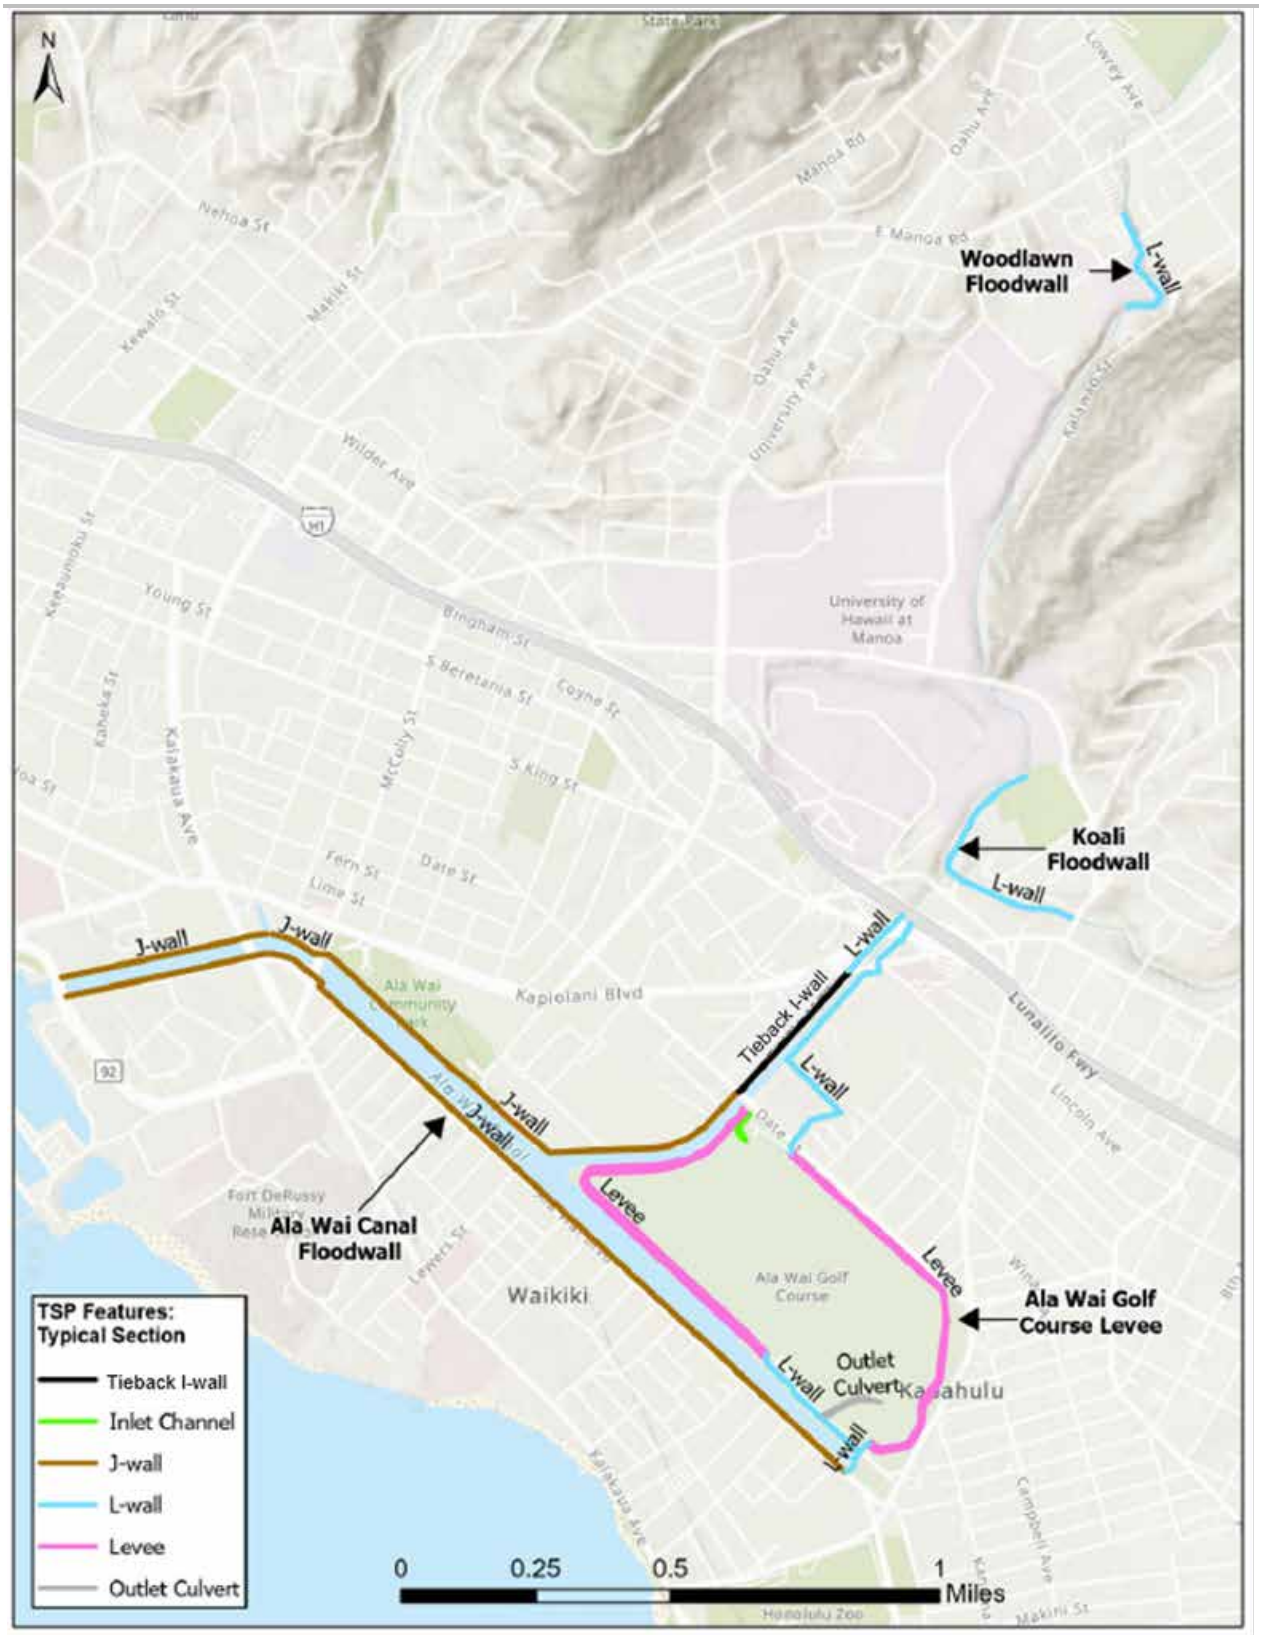

Figure 11-3: Conceptual Diagram of Alternative 5.3

Ala Wai Flood Risk Management GR Study - Management Measure Tracking Spreadsheet

last updated: September 30, 2022

Tracking #	Measure Name	Basin	Description	Type	Status	Notes/Rationale
1	Flap gates on storm drains	Ala Wai Canal	During high tide Ala Wai Blvd. between Kalakaua and the cul de sac ending at Ala Moana Blvd. floods. Ala Wai canal in this area needs flap gates to keep Ala Wai Canal water from flooding storm drains and flooding streets.	Gates	Retained	Provision, modification, and/or maintenance of drainage systems to capture and convey interior runoff in urban areas is a non-Federal responsibility and therefore cannot be included in a recommendation made as a result of this general reevaluation report. However, this study can make modifications to natural stream channels or previously modified natural waterways that help reduce backup within adjacent drainage systems. Flap gates will be considered for all streams/areas that meet this criteria.
2	Elevate canal walls	Ala Wai Canal	Increase canal capacity by elevating the existing canal floodwalls	Floodwall/Berm	Screened Out	Components and concepts of this measure are included in #193. This measure will be screened out for redundancy.
3	Deepen the canal	Ala Wai Canal	Excavate to deepen the existing canal and stabilize existing floodwalls.	Channel Modification	Screened Out	Dredging to the maintenance elevation is encouraged for the City to maintain consistently. Deepening the canal further than the maintenance elevation is generally not recommended due to the stability of canal walls and slope stability. Increasing storage of the canal can technically reduce flooding but not without instability of the structural components of the bridges and canal walls. The integrity of the canal walls as-is would not withstand excavation - only replacing with an entirely new system would. Further analysis is needed to determine the stability of bridge pier and footings. See measure 5.
4	Deepen canal for periodic pump drainage	Ala Wai Canal	Dig existing walls deeper to turn the canal into a periodic pump drainage to address inundation by all three sources of flooding	Channel Modification	Screened Out	Digging the existing walls deeper is not recommended due to their strucutral integrity. Pumping the canal in its entirety to increase storage capacity is not recomended due to stability of the existing canal walls. Hydrostatic pressure is likely needed for structural stability. Technical analysis needed to determine structural stability of bridge piers and footings. See measures 5 and 197.
5	Deepen the canal, replace canal walls with higher flood protection	Ala Wai Canal	Dredge canal down to its original depth of 15' to 25', and replace the degraded infrastructure with new canal walls that are set for greater flood protection	Channel Modification	Retained	The integrity of the canal walls as-is would not withstand greater dredging efforts than maintence dredging - only replacing with an entirely new system would. Further analysis is needed to determine the appropriate wall height, the stability of bridge pier and footings, and the optimal depth that balances slope stability and flood storage. Other considerations include dredged material contamination. Upon hydraulic analysis, dredging the canal to its original design depth can reduce flood risk. However, a more appropriate canal design depth/cut will be evaluated considering canal wall stability, bridge piers, and the level of contamination below the current dredged depth. This measure will be retained until a conclusive impact to water surface elevation can be made with appropriate assumptions.
6	Widen canal	Ala Wai Canal	Widen the canal to provide greater flow and storage capacity.	Channel Modification	Screened Out	Widening the canal for the entire length would require extensive real estate acquisitions with significant costs. Widening the eastern end of the canal would reduce the real estate acquisition costs, but did not provide more flood storage. The capacity of the canal is ultimately driven by tidal influence. Expanding canal storage through the use of floodwalls and/or utilizing existing storage areas along the canal (e.g., golf course, Ala Wai Community Park) are more efficient and are considered elsewhere.
7	Dredge Ala Wai Canal to original depth	Ala Wai Canal	Dredge canal down to its original depth of 15' to 25' since current dredging only goes down to 12'.	Channel Modification	Screened Out	Dredging to the maintenance elevation is encouraged for the City to maintain consistently. Deepening the canal further than the maintenance elevation is generally not recommended due to the stability of canal walls and slope stability. Increasing storage of the canal can technically reduce flooding but not without instability of the structural components of the bridges and canal walls. The integrity of the canal walls as-is would not withstand excavation - only replacing with an entirely new system would. Further analysis is needed to determine the stability of bridge pier and footings. See measure 5.
8	Dredge Manoa-Palolo	Lower Watershed	Dredge the Manoa-Palolo channel	Channel Modification	Screened Out	The Manoa-Palolo Canal is currently dredged to its design depth. Dredging further would impact canal wall stability and provide no additional benefit to the surrounding communties due to the tidal influence (below Date Street) and steep channel slope (above Date St). No further dredging is recommended.
9	Canal clean ups	Ala Wai Canal	Involve the community to conduct regular clean ups	Debris Management	Screened Out	Organizing clean-ups is outside the scope of the current study. Community involvement for clean ups after construction is a possibility; however, those initiatives those initiatives need to be initiated by other entities.
10	Effective Microorganisms (EM) to eliminate sludge	Ala Wai Canal	Use "genki balls" to clean up and eliminate sludge in the canal. These healthy microorganisms work to digest sludge in the canal which will help not only to evacuate water from the canal quicker, but also restore the ecosystem and reduce frequency for dredging.	Water Quality	Screened Out	Sludge eliminated by the genki balls would have to be extensive enough to reduce flood risk in order to be justified under the current study. Genki balls would eliminate the organic matter within the canal, which only makes up a small portion of material within the canal. Genki balls as a standalone measure would not provide enough reduction in material to increase storage capacity of the canal and reduce flood waters. Genki balls could be incorporated into a separate effort focused on ecosystem restoration.
11	Oysters to clean the canal	Ala Wai Canal	Use oysters as filters to clean the canal waters.	Water Quality	Screened Out	Improving water quality is outside the scope of this project. Oyster filters could be incorporated into a separate effort focused on ecosystem restoration.

Tracking #	Measure Name	Basin	Description	Type	Status	Notes/Rationale
12	Debris management	Watershed Wide	Better manage the debris that ends up in the canal	Debris Management	Screened Out	Debris management will likely be most effective when utilized in conjunction with other measures (e.g., combined storage/debris management basins, structural modifications to bridges) (see measure #96). Channel clearing and modification can be incorporated into the study. However, long-term clearing programs or periodic stream cleanups cannot be included in a recommended plan as it is outside of the authority of USACE to partner in ongoing maintenance efforts. The study can include the recommendation to develop or re-evaluate a comprehensive debris management plan (see response to measure #188). This measure will be screened out for redundancy as components and concepts of this measure are seen in measure #96.
13	Submersible pumps	Ala Wai Canal	Use underwater pumps to create a lower profile pumping station	Pumps	Screened Out	Components and concepts of this measure are included in #197. This measure will be screened for redundancy.
14	Miter gates	Ala Wai Canal	Use several smaller radius miter gates to minimize visual impacts (to be used in conjunction with pump station)	Gates	Screened Out	Components and concepts of this measure are included in #197 and #196. Pump and gate design will be determined based on land use and inflow, following USACE regulations and best practices. This measure will be screened for redundancy.
15	Lowered gate structure	Ala Wai Canal	Use a lowered structure underwater that could be raised in an event instead of a miter dam. (to be used in conjunction with pump station)	Gates	Screened Out	Components and concepts of this measure are included in #197 and #196. Pump and gate design will be determined based on land use and inflow, following USACE regulations and best practices. This measure will be screened for redundancy.
16	Retractable flood barriers	Ala Wai Canal	Relocate pump station to the golf course. Use a series of retractable flood barriers that would allow for 4 rowing lanes (44' wide) across the width of the canal.	Gates	Screened Out	Components and concepts of this measure are included in #197 and #196. Pump and gate design will be determined based on land use and inflow, following USACE regulations and best practices. This measure will be screened for redundancy.
17	Prevent bulky refuse from clogging streams	Watershed Wide	Some people experiencing houselessness/homelessness are living near the streams and disposing of large, bulky items there. Discarded items include air conditioners, refrigerators, carpets and clothing; these block the canal and prevent water and debris from flowing freely down the stream. Locations identified: Woodlawn Bridge, Dole Street Bridge, Lower Waahila Ridge, Kanewai Park, St. Louis Heights Bridge, Kapiolani behind Service Station, Kaimuki High School, Date St, etc.	Debris Management	Screened Out	Managing houselessness/homelessness is outside the scope of the USACE feasibility authority; however, debris management can be included within the design of other project features. See measure #96. See response to measure #188 that addresses long-term debris management.
18	Pump via conduits	Ala Wai Canal	Pump flood waters via pipes, conduits or microtunnels to harbor instead of using high walls	Tunnel/Conduit	Screened Out	Components and concepts of this measure are included in #20 and 197. This measure will be screened out for redundancy.
19	Change canal floor slope	Ala Wai Canal	Change the floor slope of the canal to push water out quicker; excavate to 25' deep at the Ala Moana bridge	Channel Modification	Screened Out	Dredging to the maintenance elevation is encouraged for the City to maintain consistently. Deepening the canal further than the maintenance elevation is generally not recommended due to the stability of canal walls and slope stability. The integrity of the canal walls as-is would not withstand excavation - only replacing with an entirely new system would. However, dreding at strategic locations, as opposed to the entire canal, can be investigated. Further analysis is needed to determine the stability of bridge pier and footings. Further analysis also needed to determine the sensitivity of the canal slope to reducing flood elevations during a storm event. This measure includes concepts and components that are included in measure #5. This measure will be screened out for redundancy, as the slope and depth of the canal will be investigated in the same fashion.
20	Microtunnel through Waikiki	Ala Wai Canal	Several microtunnels along the canal (i.e. under Paoakalani Ave, Ohua Ave, Liliuokalani Ave, Kanekapolei St, Nohonani St, Lewers St, Kalaimoku St, etc.), going under Waikiki and straight out to the ocean to increase conveyance	Tunnel/Conduit	Screened Out	Microtunnels (or system of bypasses under Waikiki) was found to not have significant flood risk management impacts after extensive hydraulic modeling efforts. This measure will be screened from further consideration.
21	2nd outlet on east end of canal (open canal)	Ala Wai Canal	Open up the east end of the canal with an open system extending down Paki Ave and makai through Kapiolani Park	Channel Modification	Retained	Identified as a priority for modeling. All possible options for daylighted and underground 2nd outlets will be explored. Minimizing property acquisitions would reduce costs. Likely to have significant water quality and environmental effects.
22	2nd outlet on east end of canal (underground)	Ala Wai Canal	Extend the canal underground with a box culvert running beneath Paki Ave down Kapahulu Ave. or Monsarratt Ave.	Tunnel/Conduit	Screened Out	Components and concepts of this measure are similar to those in measure #21. All possible options for daylighted and underground 2nd outlets will be explored. This measure will be screened out for redundancy.
23	East canal buried pipe system	Ala Wai Canal	Put a buried pipe system with a two way pump on the east end of the canal. During storms the pump can evacuate water from the canal or as regular maintenance the pump can reverse to bring fresh sea water to help circulate the canal. 30 cfs of seawater can accomplish both reduced sedimentation and improved water quality.	Tunnel/Conduit	Screened Out	Components and concepts of this measure are included in #22. The improvement to water quality with reverse pumping is a consideration that will not impact flood risk, but secondary water quality benefits associated with this and other flood risk management measures can be captured as part of the documentation of comprehensive benefits. This measure will be screened out for redundancy.
24	Tunnel for additional outlet through Waikiki	Ala Wai Canal	Tunnel under Waikiki at Fort Derussy or through an underground pipe starting at the MP-canal confluence and shooting straight out to sea.	Tunnel/Conduit	Screened Out	Components and concepts of this measure are included in #20 and #22. The location and size of a second outlet will be determined by environmental and engineering analyses. This measure will be screened out for redundancy.
25	Underwater pipes in canal	Ala Wai Canal	Use underwater pipes laid on the floor of the canal to redirect floodwaters directly to the harbor. These pipes could redirect flows directly from Makiki or the Manoa-Palolo straight out to sea without entering the Ala Wai canal.	Tunnel/Conduit	Screened Out	Underwater pipes laid on the canal floor would not provide increased conveyance for Makiki or Manoa-Palolo as stated. Instead, other measures will be considered to bypass water from those streams directly to the harbor via tunnels or existing storm sewers. Pipes laid on the canal floor will reduce capacity within the canal. The measure will be screened as other measures with more effective conveyance will be explored.

Tracking #	Measure Name	Basin	Description	Type	Status	Notes/Rationale
26	Canal sluice gates	Ala Wai Canal	Design sluice gates to account for storm surge and high tides to prevent backflow through manhole covers	Gates	Screened Out	Sluice gates specifically to address coastal flooding is outside the scope of this study; however, flap gates to prevent backflow from elevated water surfaces within the canal has been identified as a separate measure, see #1.
27	Floodwalls on Waikiki side of canal only	Ala Wai Canal	Build floodwalls only on the Waikiki side of the canal. Do not build floodwalls on the Moiliili side of the canal.	Floodwall/Berm	Screened Out	Placing floodwalls on only one side of the canal could induce damages on the other side. This study seeks to reduce flood risk for all areas in a cost-effective and environmentally conscious way. Therefore, measures seeking to implement floodwalls adjacent to the canal would consider both sides. Floodwalls are considered a Tier 2 measure for modeling purposes. Modeling of storage features needs to occur prior to modeling this measure in order to assess an accurate water volume. See measure #193.
28	Submersible pump & gate at canal mouth	Ala Wai Canal	Submersible pumps and floodgate at Ala Moana Bridge. Excavate entire canal to 25' deep from Kapahulu to harbor. Pre-pump canal ahead of a storm. Smaller submerged pumps at Manoa confluence to push water towards harbor. Build a dam under McCully and/or Kalakaua bridges with pump station.	Pumps	Screened Out	Pumping the canal ahead of a storm to max capacity is not recomended due to stability of the existing canal walls. Hydrostatic pressure is likely needed for structural stability. New canal walls, functioning as floodwalls are being considered in measure #193. Further analysis is needed to determine the appropriate wall height, the stability of bridge pier and footings, and the optimal depth that balances slope stability and flood storage. Pump and gate as a standalone measure, as to not drain the canal ahead of a storm, will be carried forward for further consideration under #196 and 197.
29	Mauka canal floodwall	Ala Wai Canal	Raise mauka canal wall so it is the same height as the Waikiki wall. This floodwall would need to extend past Iolani School up to the Date St. bridge	Floodwall/Berm	Screened Out	Components and concepts of this measure are included in #193. This measure will be screened out for redundancy.
30	Pump & Gate at canal mouth	Ala Wai Canal	Pump and gate at Ala Moana Bridge. Pre-pump to drain canal ahead of a storm for additional storage capacity. Pump gates can hold back storm surge up the canal, as well as facilitate pump down and out of the canal against high tide conditions. A pump gate can also ease the cleaning/dredging of the canal without using dredge (use bulldozer instead with drained canal).	Pumps	Screened Out	Pumping the canal ahead of a storm to max capacity is not recomended due to stability of the existing canal walls. Hydrostatic pressure is likely needed for structural stability. Pump and gate as a standalone measure, as to not drain the canal ahead of a storm, will be carried forward for further consideration under #196 and 197.
31	Dam at canal mouth	Ala Wai Canal	Replace high wall ideas on either side of the Ala Wai canal with a dam at the end of the canal where it exits by Ala Moana Blvd. (at the narrow opening after Ala Moana Blvd between the Waikiki Yacht Club and the Prince Waikiki Hotel). Force the water to exit from the Ala Wai water channel but not enter from the ocean into the Ala Wai canal. Secondly, water from high rain days could be diverted with above ground pipes away from the Ala Wai canal.	Dam	Screened Out	A dam at the mouth of the canal near the harbor would need considerably higher canal walls for greater storage and a pump system. The intent of this measure is captured under #193 and 196.
32	Retention or Detention pond	Ala Wai Canal	Implement retention or detention pond or a constructed wetland at Ala Wai Community Park.	Wetland/Floodplain	Screened Out	A detention structure at the Community Park will be considered as part of a floodwall system for the canal. The park itself would not provide enough storage for above or below ground storage as the area is already subject to flooding. Components of this measure will be included in measure #193. A detention structure at the park will be screened as stated. A wetland will not provide flood risk reduction for future watershed conditions due to sea level rise. The park is naturally a floodplain and adding wetland features will only reduce localized runoff for very frequent storm event, i.e. typical rain showers. A wetland feature at the park will have no impact to runoff and storage for larger storm events. A wetland will be screened from future consideration.
33	Redesign of Ala Wai Community Park	Ala Wai Canal	Redesign the Ala Wai Community Park into a flood park with wetlands and taro patches. Redesign areas of the park for community access and visitor education.	Wetland/Floodplain	Screened Out	Components and concepts of this measure are included in measure #32. This measure is screened out for redundancy.
34	Detention basin for mauka drainage storage	Ala Wai Canal	There are a number of drainage system outfalls that either run through the Ala Wai Community Park or along its perimeter (drainage systems coming down Isenberg or University for example). Reengineer the baseball fields to use as detention basins serving these drainage systems. Perhaps rerouting the section of shared use path that runs along the canal to the mauka side of the baseball fields and double as a berm.	Detention	Screened Out	Components and concepts of this measure are included in measure #32. This measure is screened out for redundancy.
35	Pump station on golf course	Ala Wai Canal	Put pump station on the Ala Wai golf course if one is needed.	Pumps	Screened Out	Components and concepts of this measure are included in #197. This measure will be screened for redundancy.
36	Underground pump station	Ala Wai Canal	Build pump station partially underground for less visual impact.	Pumps	Screened Out	Components and concepts of this measure are included in #197. This measure will be screened for redundancy.
37	Octopus Plan	Ala Wai Canal	Put pump station on the Ala Wai golf course and pipe the intakes from critical locations and outtakes directly to the harbor.	Pumps	Screened Out	The performance expectation of 1 pump managing all systems of the octupus plan is not efficient and provides little redundancy in an emergency. However, the components and concepts of this measure are included in #66 and #197. This measure will be screened for redundancy.
38	Golf course debris basin	Ala Wai Canal	Create a debris basin at the golf course as a first flush before entering the canal	Debris Management	Screened Out	A debris basin may be included in the design of a larger, more comprehensive flood risk management feature at the golf course that also incorporates flood storage (see measure #39), but is not be considered as a standalone measure.

Tracking #	Measure Name	Basin	Description	Type	Status	Notes/Rationale
39	Golf course detention basin - excavation	Ala Wai Canal	Excavate the golf course to increase storage capacity	Detention	Retained	Identified as a priority for modeling. Modeling of the golf course area will seek to identify the optimal solution, including how/where to divert water from, extent of additional storage needed to reduce flood risk, and potential for application of natural and nature-based measures either as stand-alone measures or in conjunction with structural components. Detention will include the impacts to sea level rise and groundwater infiltration.
40	Golf course detention basin - berms	Ala Wai Canal	Utilize the entire golf course with higher berms for increased storage capacity	Detention	Screened Out	Components and concepts of this measure are included in measure #39. This measure is screened out for redundancy.
41	Golf course wetlands	Ala Wai Canal	Convert the golf course to wetlands. See Bea Aglibot's "A Unified Landscape: Reconnecting the Ala Wai Watershed to Ancient Waikīkī" which can be found here on ScholarSpace: https://scholarspace.manoa.hawaii.edu/handle/10125/55834	Wetland/Floodplain	Screened Out	Components and concepts of this measure are included in measure #39. This measure is screened out for redundancy.
42	Manoa-Palolo reroute through golf course	Ala Wai Canal	Divert the Manoa-Palolo into the golf course; construct golf course as a wetland with native plants to clean the water before exiting into the canal.	Bypass	Screened Out	Components and concepts of this measure are included in measure #39. This measure is screened out for redundancy.
43	Ala Wai Canal flow through system	Ala Wai Canal	Reroute the Manoa-Palolo from Date St. into the golf course, with an open or closed channel along the north and east boundaries of the golf course, connecting to the east end of the Ala Wai canal. This will help flush and circulate the east end of the canal, also reducing the health risk of bacteria	Bypass	Screened Out	Components and concepts of this measure are included in measure #39. The benefits to water quality can be captured as part of the documentation of comprehensive benefits. This measure is screened out for redundancy.
44	Divert floodwaters to golf course	Ala Wai Canal	Intercept the floodwaters upstream and divert them to the golf course for storage	Bypass	Screened Out	Components and concepts of this measure are included in measure #39. This measure is screened out for redundancy.
45	Golf course underground parking structure	Ala Wai Canal	Create an underground parking structure at the golf course that connects to Waikiki and can be used as flood storage.	Detention	Screened Out	Water table along the canal is high; an underground structure on the golf course will require additional floodproofing which will not have as much economic benefits as an above ground structure where floodproofing is not required. This measure is screened from further consideration since above ground storage provides sufficient flood risk management benefits.
46	Create a community park	Ala Wai Canal	Turn the golf course into a flood park that's usable for the community ("Ala Wai Park") or reinvent it as a cultural park that doubles as a detention basin.	Detention	Screened Out	Components and concepts of this measure are included in measure #39. This measure is screened out for redundancy.
47	Excavate and rearrange golf course	Ala Wai Canal	Excavate mauka side of golf course to accept mauka surface run-off and use that side as a driving range and run-off detention basin. Put a 12' wall on makai side and pump station built to transfer water from it to a much larger golf course detention basin with a 12' wall around it.	Detention	Screened Out	Components and concepts of this measure are included in measure #39. This measure is screened out for redundancy.
48	Delta at Manoa-Palolo confluence with wetlands	Ala Wai Canal	Turn Ala Wai golf course into a lagoon park (Ala Wai Lagoon Park) to absorb storm surges. Construct a delta at the junction of Manoa-Palolo and the Ala Wai Canal for silt and debris capture. This would function to filter stream debris before entering the canal and the golf course would act as a sponge to absorb storm surge and flooding.	Wetland/Floodplain	Screened Out	Components and concepts of this measure are included in measure #38 and #39. This measure is screened out for redundancy.
49	Install silt dams	Watershed Wide	Build silt dams in all accessible gullies. The silt dam is composed of local rock from the immediate stream bed, encased in wire fencing. The rushing water is slowed as it goes through the dam, the gravel and dirt drop out behind the dam, the water has more time to penetrate subsoil and rock - replenishing the fresh water lens.	Grade Control Structure	Screened Out	Components and concepts of this measure are included in measure #68. This measure is screened out for redundancy.
50	Series of silt berm/dams	Watershed Wide	Build a series of low rock (under 6' high) silt berm/dams that direct floodwaters into the natural basin of the valley head. In essence, this creates a relatively dry basin to detain water only during flooding events. The shallow, bowl-like existing topography (with some excavation) could be used as an advantage to allow the waters to spread out and slowly either be absorbed into the water lens or make a more controlled exit into the valley below. Silt dams also use the existing rocks in the valley and avoid bringing in materials from outside. They can hold back some of the soil that normally ends up in the Ala Wai and ocean beyond. This way, the stream beds are unaltered, the water is given room to expand, and provides a more natural way for water to be "guided." The concept is based on the 'auwai of a Hawaiian lo'i, on a much larger scale.	Grade Control Structure	Screened Out	Components and concepts of this measure are included in #49. This measure is screened out for redundancy.
51	Stream restoration	Palolo	Stream restoration opportunities and/or hybrid reintroductions of pool-riffle run stream conditions	Channel Naturalization	Screened Out	Components and concepts of this measure include naturalization (#147), grade control structures (#67 & #157), and fishponds (#94). This measure will be screened out for redundancy.
52	Hausten Ditch conduit	Ala Wai Canal	Put a conduit that goes under the Hausten Ditch - the water could flow to the Ala Wai Park detention basins	Tunnel/Conduit	Screened Out	Concepts of this measure are include in #66. This measure will be screened out for redundancy.
53	Kaimuki High Detention Basin	Ala Wai Canal	Utilize Kaimuki High School's football field	Detention	Retained	This measure will be considered as a part of the Ala Wai Canal floodwall as extended upstream of Date Street on the Manoa-Palolo Canal or as a levee/floodwall in the playing fields of the high school to protect the community and school behind the levee, as a standalone measure.

Tracking #	Measure Name	Basin	Description	Type	Status	Notes/Rationale
54	Streamside walking path	Ala Wai Canal	Construct a nice streamside walking path adjacent to Kaimuki High School	N/A	Screened Out	All measures must be designed to reduce flood risk. A walking path as a stand-alone measure that does not alter flood risk could not be included under the current study authority. However, recreational components can be incorporated into measures that do reduce flood risk (e.g., walking path along elevated berm) and could be considered as a part of those measures.
55	Subsurface Kanewai Tunnel	Manoa	Subsurface tunnel from Kanewai Community Park to the harbor using gravity flow	Tunnel/Conduit	Screened Out	Components and concepts of this measure are included in #66 (SWIFT Tunnels). Each tunnel investigated in the Manoa subbasin will incorporate land use, environmental impacts, and inflow to determine the location and size of tunnels. This measure will be screened for redundancy.
56	Kanewai detention & bypass conduit	Manoa	Detention basin at Kanewai Community Park and a conduit that bypasses Manoa-Palolo and Ala Wai canal. The conduit inlet would begin at the detention basin's low flow outlet. The conduit could be laid either along the stream/canal bed or sides, and the conduit outlet located at the Ala Wai boat harbor, using gravity flow. With conduit located alongside the stream/canal, it can serve as a dual purpose flood barrier (berm) with a raised bike path and sidewalk on top.	Tunnel/Conduit	Screened Out	Components and concepts of this measure are included in #173 and #55. This measure will be screened out for redundancy.
57	Kanewai Detention basin	Manoa	Use Kanewai as a detention basin (preference for underground detention)	Detention	Screened Out	Components and concepts of this measure are included in measure #173. This measure will be screened out for redundancy.
58	Kanewai bypass to Golf Course	Manoa	Intercept the water near Kanewai and pipe or via underground tunnels convey the flood waters to the Ala Wai Golf course so that a detention basin is not needed at Kanewai.	Bypass	Screened Out	Components and concepts of this measure are included in #55 and 38. This measure will be screened out for redundancy.
59	Kapiolani Park detention basin	Lower Watershed	Divert water to Kapiolani Park for additional flood storage	Detention	Retained	Kapiolani Park as a multi-purpose detention may be feasible. Since gravity flow is insufficient to the park from the canal, a pump would be needed. Pump capacity, placement, and cost will be factors in its viability moving forward within the study process. Park storage capacity may be limited due to the shallow groundwater table.
60	Berm around Iolani and Ala Wai Elementary Schools	Ala Wai Canal	Put in a berm along Laau St, along Hihiwai St., wrap around the Ala Wai elementary playground (makai direction), and connect to a floodwall along the canal. This would provide protection to Iolani School, Ala Wai Elementary school, and the mauka side neighborhoods (the Manoa-Palolo overtopped in the past). Utilize the green spaces (softball field, dog park, playground) outside the line of protection for additional storage capacity.	Floodwall/Berm	Screened Out	Components and concepts of this measure include floodwalls/berms along the Ala Wai Canal (#193) and redesigning green spaces along the canal for additional storage or wetlands (#32). The alignment of the floodwall/berm system along the canal would be finalized during design phase and will take into account the schools. This measure will be screened out for redundancy.
61	Nature based approach to integrate recreation	Watershed Wide	Use nature based approach that integrates recreation into reserved flood areas (when not flooded). This can enhance this project as a community asset. Maybe tie into Lei of Parks idea (system of paths and bike lanes linking the City's regional and local parks).	Wetland/Floodplain	Screened Out	Recreational components can be incorporated into a flood risk management plan and can potentially be cost shared with the local sponsor. These opportunities will be pursued as appropriate within this study. The components and concepts of this measure are included in #94. This measure will be screened out for redundancy.
62	Sponge city	Watershed Wide	Urban development system that absorb, store, infiltrate, and purify rainwater. Examples include interconnected greenways and waterways, contiguous open green spaces, green roofs, porous design interventions and drainage systems, water savings, and recycling initiatives. Look at flood mitigation outside the US such as China, Singapore: https://earth.org/sponge-cities-could-be-the-answer-to-impending-water-crisis-in-china/ or https://www.youtube.com/watch?v=GsBDpp08kwE	Impervious Surface Reduction	Screened Out	Sponge City costs about $15-22 million for each square kilometer, which is equivalent to $750M-$1.1B for the 50 sq. km. of the Ala Wai watershed. This concept is ultimately screened out for redundancy as the components and concepts of reducing impervious surfaces is captured under measure #104.
63	Makiki Stream conduit	Makiki	Put a conduit that goes under the Makiki Stream and divert the water directly out to the harbor	Tunnel/Conduit	Screened Out	This alignment as proposed poses risks and difficulties during construction, such as pumping and a cofferdam during a storm event as well as side slope stability of the existing retaining wall during placement of the new conduit under the stream. This measure will be screened from further consideration. The team will focus on other measures along Makiki Stream, such as modifying the stream's entry angle (#64) or using existing infrastructure to divert water (#130).
64	Modify Makiki Stream entry angle	Makiki	Modify the angle that the Makiki Stream enters the canal to minimize additional head on the water trying to exit near McCully. The current stream outflow has less than a 90 degree angle, increasing the chance to produce higher water level with backwater during a flood, accumulate sediment, higher cost on channel wall maintainers, etc.	Channel Modification	Screened Out	The Makiki stream angle is not the main source of flooding for much of the lower watershed. Localized flooding may occur at the confluence for certain storm sizes due to the extreme angle of the stream into the canal, but main source of flooding is dictated by the tide levels at this location. The channel will be considered for modification where possible. Additionally, modifying the angle of the stream entry would require acquiring a significant amount of real estate. This measure will be screened from further consideration. The results from this analysis informed the screening for similar channel modifications suggested elsewhere within the tracker.
65	Forest management	Upper Watershed	Manage the forest above Waiakeakua and along Waihi. The forest is changing and becoming increasingly degraded by pigs and invasive plants and trees, thus reducing the resiliency of the watershed to major flooding events. We should look at the watershed as a whole starting at the top where the majority of the rainfall is and the natural systems in place that may be improved to mitigate flooding.	Reforestation	Retained	Wildlife management for invasive pigs is outside the USACE authority for this study and cannot be further considered. Modeling is being conducted to quantify the extent to which forest management reduces downstream flood risk. Modeling is ongoing and this measure will be retained until a conclusive decision can be made.

Tracking #	Measure Name	Basin	Description	Type	Status	Notes/Rationale
66	SWIFT tunnels	Watershed Wide	Two 12' diameter subsurface tunnels (~40' under) from Manoa and Palolo shooting straight out to sea using gravity flow	Tunnel/Conduit	Retained	The SWIFT tunnels are retained for further consideration, unless noted otherwise. There are several considerations that the team will investigate including updating costs to include real estate acquisition, preliminary engineering and design, construction management, and inflation, as well as environmental impacts that freshwater will have on the aquatic environment. The technical team will re-evaluate the inlet and outlet structures and determine a comprehensive conceptual design that is a standalone measure, separate from the original design by OCEANIT, which complimented the former USACE design. For more information on the original tunnel concept see the November 2020 public meeting presentation video at: https://www.oceanit.com/project/ala-wai/
67	Install baffling in streams	Watershed Wide	Install baffling in the streams to slow the water down.	Grade Control Structure	Screened Out	Components and concepts of this measure are included in measure #68. This measure is screened out for redundancy.
68	Check dams	Manoa	Construct check dams in Manoa to slow the water down ahead of areas prone to flooding	Grade Control Structure	Screened Out	After modeling the Manoa stream, there are very few areas that have the channel capacity for induced water surface elevations as a result of check dams or other grade control structures. The area between Woodlawn Bridge to the Jakuan Tea House was evaluated for grade control structures. This measure was intended to dampen the peak flow and increase attenuation for smaller storm events. The impacts of the grade control structure were localized, minimal for even small storm events, and negligible to the overall system. Similar results were found throughout the entire basin. Grade control structures and other similar measures to slow water such as baffling and silt dams will not be considered for further evaluation.
69	Kahaloa Bridge widening	Manoa	Widen the Kahaloa bridge to allow a larger volume of storm water drainage runoff feeding into Manoa Stream just above the bridge.	Bridge Modification	Screened Out	Components and concepts of this measure are included in measure #118. This measure is screened out for redundancy.
70	Drop structure	Manoa	Install a “falls” just before the bridge at Woodlawn Drive to help push the silt and debris past the bridge to prevent future floods.	Grade Control Structure	Screened Out	Falls upstream of Woodlawn Bridge would increase water surface elevations upstream of the bridge. If the falls are intended to increase velocity in order to move debris downstream, the team recommends reducing the sedimentation through debris catchments and regular maintenance.
71	Woodlawn Bridge bypass box culvert	Manoa	Create a bypass box culvert that traverses around both bridge abutments and exit into the existing stream channel on the south side of Woodlawn Drive. As an added precaution the catch basin and the drain pipes along Woodlawn Drive number and sizes could be increased.	Bypass	Screened Out	Hydraulic modeling determined that any additional bridge bypass or bridge modification at this location would not reduce flood impacts due to the volume of water and low terrain elevation on the right bank of the stream. Other flood risk management features are being explored in this area, including a floodwall, a bypass, and a channel modification.
72	Manoa Stream Dredging	Manoa	Annually dredging Manoa Stream from where the stormwater drainage ditch feeds into the stream from the Woodlawn Street drainage to the end of the stream area at the end of the Manoa Valley District Park	Channel Modification	Screened Out	Components and concepts of this measure are included in measure #168 (Channel modification). Maintenance following construction will be a non-Federal responsibility. See response to measure #188 that addresses long-term debris management. This measure will be screened out for redundancy.
73	Kahaloa Dr. stream modification	Manoa	Slow down or reduce the volume of water flowing at Kahaloa Dr. where a stormwater drainage ditch feeds into Manoa Stream. (historically a flood area)	Channel Modification	Screened Out	The stormwater ditch above Kahaloa Drive does not meet the minimum flow requirements of 800 cfs at a 10% AEP event. However, improvements to Manoa Stream could help to reduce backwater effects at the stormwater ditch. Components and concepts of Manoa Stream channel modification are included in measure #168. This measure will be screened out for redundancy.
74	Kahaloa Ditch entry angle modification	Manoa	Modify the angle that the drainage ditch upstream of Kahaloa Drive enters into the Manoa Stream. The sharp 90 degree bend creates a backwater effect inundating the homes surrounding that area.	Channel Modification	Screened out	The stormwater ditch above Kahaloa Drive does not meet the minimum flow requirements of 800 cfs at a 10% AEP event. However, improvements to Manoa Stream could help to reduce backwater effects at the stormwater ditch. Components and concepts of Manoa Stream channel modification are included in measure #168. This measure will be screened out for redundancy.
75	Subsurface Manoa Park Tunnel	Manoa	Subsurface tunnel from Manoa Valley District Park to the harbor using gravity flow	Tunnel/Conduit	Screened Out	Components and concepts of this measure are included in #55 and 66. This measure will be screened out for redundancy.
76	Manoa Park Detention Basin	Manoa	Use Manoa Valley District Park as a detention basin (like Randolph Basin in Tucson) to capture peak flooding above Lowrey Ave and slow release to watershed below.	Detention	Screened Out	Components and concepts of this measure are included in measure #172. This measure will be screened out for redundancy.
77	SWIFT tunnels with flood gate & pump	Watershed Wide	SWIFT tunnels in Manoa and Palolo combined with a flood gate and pump at the Ala Moana bridge. Use 100% of the canal for detention. During this time all storm water will be pumped to the ocean via SWIFT or pipes. We can maintain a 0' MSL until the peak flows hit the Ala Wai Canal. Flood gates can be a series of small miter gates in 25-30' sections. Should sea level rise occur we can add a lock system to one of them for recreation passage in the future.	Tunnel/Conduit	Screened Out	SWIFT tunnels are under consideration and are Tier 3 for modeling priority - See response for measure 66. Other pipes/bypasses from the canal to the ocean are also under consideration - See response for measures 20, 196, & 197. Pumping the canal to 0' MSL is not recomended due to stability of the existing canal walls. System can only be considered if canal walls are replaced due to their degraded integrity.
78	Upper watershed conduit to Golf Course	Watershed Wide	Intercept flood waters upstream (Manoa and/or Palolo) via pipes, conduits, or microtunnels to the Ala Wai Golf Course detention area.	Tunnel/Conduit	Screened Out	Components and concepts of this measure are included in #66, 55, 161, and 39. This measure will be screened out for redundancy.

Tracking #	Measure Name	Basin	Description	Type	Status	Notes/Rationale
79	SWIFT tunnels with additional intake and pump	Watershed Wide	Same as SWIFT Tunnels but with additional intake in McCully utilizing a pump to drain the low-lying area (this would require the Manoa SWIFT tunnel to run directly below McCully)	Tunnel/Conduit	Screened Out	SWIFT tunnels under consideration and are Tier 3 for modeling priority - See response for measure 66. Provision, modification, and/or maintenance of drainage systems to capture and convey interior runoff in urban areas is a non-Federal responsibility and therefore cannot be included in a recommendation made as a result of this general reevaluation report. However, this study can make modifications to natural stream channels or previously modified natural waterways that help reduce backup within adjacent drainage systems. Pump can also be justified if additional flow into the system causes induced flooding at McCully. Components and concepts of this measure are captured in #66 and 80. This measure will be screened out for redundancy.
80	Add a pump to the storm drainage system in McCully-Moiliili	Lower Watershed	Add a pump to the storm drainage system in McCully and other areas that pooling occurs (at the "bottom of the bowl").	Pumps	Retained	Provision, modification, and/or maintenance of drainage systems to capture and convey interior runoff in urban areas is a non-Federal responsibility and therefore cannot be included in a recommendation made as a result of this general reevaluation report. However, this study can make modifications to natural stream channels or previously modified natural waterways that help reduce backup within adjacent drainage systems. Pump can also be justified if additional flow into the system causes induced flooding at McCully.
81	Divert floodwaters to underground karsts	Lower Watershed	Divert floodwaters to the existing karsts that run under Moiliili and connect with the ocean.	Bypass	Screened Out	Very technically challenging due to the unpredictable nature of karst features and the possibility that increased water flows could cause flooding or sinkholes elsewhere.
82	Natural lined streams	Palolo	Remove the concrete channelization and revert the streams back to its natural state. This will help to slow the water down.	Channel Naturalization	Screened Out	Components and concepts of this measure are included in #147. This measure will be screened out for redundancy.
83	Taro cultivation at Anuenue	Palolo	Taro cultivation in this area could be expanded. (Potential to slow water down?)	Reforestation	Screened Out	Components and concepts of this measure are included in measure #94. This measure will be screened out for redundancy.
84	Mitigate stream bank erosion	Palolo	Address stream bank erosion on probate properties, caused by upper stream concrete walls increasing stream velocity and creating waterfall effect into dirt stream; stream boulders have redirected storm stream flow into eroding private properties. Stream is owned by Chaminade/Marianist Community and does have funding for equipment and redesigning of flow that has changed over the decades.	Debris Management	Screened Out	Addressing stream bank erosion is generally outside of the USACE authority for flood risk management studies. However, USACE does have other authorities through which stream bank erosion can be addressed (i.e., Section 14 Continuing Authorities Program).
85	Palolo Park Detention basin	Palolo	Use Palolo Valley District Park for above ground or underground storage.	Detention	Screened Out	Upon re-assessing this measure, after input from a community member to adjust the inlet location above Ahe St, the detention pond was determined to not provide sufficient flood risk management impacts to the communities affected by flooding. Model results indicated localized water surface reductions within the channel and negligible water surface reductions in the overbanks (within the neighborhood) for a short distance downstream of the detention basin. This measure will be screened from further consideration. Adjacent publicly owned land was also considered for storage as a channel modification or overflow ditch. Similar results to the above description were identified for the channel modification adjacent to Palolo Valley District Park as well.
86	Underground detention - parking lots	Watershed Wide	Excavate beneath existing parking lots to create underground detention basins.	Detention	Screened Out	Above ground storage solutions are of the highest priority. The amount of storage available above ground is generally greater than storage capacity available under ground for cost-effective solutions. Additionally, the karst subsurface conditions pose challenges for underground storage. The cost required for real estate and construction methods are generally much higher for under ground storage solutions. All storage solutions under parking structures have been determined to have insufficient storage for flood risk management. This measure will be screened from further consideration.
87	Underground detention - fields	Watershed Wide	Excavate beneath existing parks and open green spaces to create underground detention basins	Detention	Screened Out	Above ground storage solutions are of the highest priority. The amount of storage available above ground is generally greater than storage capacity available under ground for cost-effective solutions. Additionally, the karst subsurface conditions pose challenges for underground storage. The cost required for real estate and construction methods are generally much higher for under ground storage solutions. One park site is retained until further analysis is complete at the Kanewai Community Park (#181). This measure will be screened for redundancy.

Tracking #	Measure Name	Basin	Description	Type	Status	Notes/Rationale
88	Manage mountain erosion	Upper Watershed	Additional debris is created by erosion of the mountain sides. The loose debris created by the slides will flow in to the drainage streams during periods of heavy rain and possibly create dams that will flood neighborhoods not identified as high flood risk.	Debris Management	Screened Out	Addressing landslides/erosion is outside of the scope of the USACE study authority; however, debris management may be possible if incorporated within other flood mitigation features.
89	Green and Complete Streets	Watershed Wide	Green and complete streets along University Ave. to provide multi-benefit community improvements including flood water management, vegetation and shade trees, environmental enhancement to support walking, biking, safe access to schools, etc.	Impervious Surface Reduction	Screened Out	The City of Honolulu is committed to the Complete Streets Law since 2012. Please refer to the City website on progress since the program was adopted. This measure will be screened out for redundancy as well, as concepts to reduce runoff are included in measure #104.
90	UH practice fields detention basin	Manoa	Pipe floodwaters to the UH practice fields for additional storage	Detention	Screened Out	This measure poses technical challenges with drilling through a mountain to pipe water in, grading, and associated costs of excavation. This area is associated with karst geology, resulting in additional challenges and risks.
91	Remove invasive trees that cause debris	Upper Watershed	Remove invasive albizia trees that have shallow roots and branches that break easily, and cause much of the debris and clogged bridges downstream.	Reforestation	Screened Out	Modeling to assess potential problem areas for debris buildup will be completed first. Specific debris management measures will then be identified. Components and concepts of this measure are included in #65. This measure will be screened out for redundancy.
92	Remove invasive plants for better groundcover	Upper Watershed	Remove invasive plants such as miconia and mule's foot fern that increase runoff and prohibits groundwater absorption. Miconia has a long history of promoting erosion, runoff, and reduces aquifer recharge in the South Pacific. Miconia is considered one of the 100 worst invasive species in the world. Replace invasive species with native plantings that can enhance recharge and reduce runoff.	Reforestation	Screened Out	Components and concepts of this measure are included in #65. Modeling will be conducted to quantify the extent to which forest management reduces downstream flood risk. This measure will be screened out for redundancy.
93	Manage feral pigs	Upper Watershed	Manage or remove feral pigs that uproot trees and cause erosion and debris downstream. Install pig fencing.	Reforestation	Screened Out	Wildlife management is outside of the USACE study authority. Debris management has been identified as a separate measure, see #96. See response to measure #188 that addresses long-term debris management.
94	Traditional Hawaiian resource management practices	Watershed Wide	Utilize traditional Hawaiian resource management practices like loko ia, loi kalo, and fishponds for sediment retention and flood mitigation.	Wetland/Floodplain	Screened Out	Traditional practices were considered for flood risk management, such as wetlands creation and invasive species removal. Wetlands creation can include lo'i kalo and reconnecting the waterways of the lower watershed. However, it was determined that these features did not reduce flood risk in the lower watershed. The golf course and other candidates for wetlands creation are generally floodplains by nature - adding wetland features will only reduce localized runoff for very frequent storm event, i.e. typical rain showers. A wetland feature will have no impact to runoff and storage for larger storm events. A wetland will be screened from further flood risk management consideration. Invasive species removal is captured under measure #65. Grade control structures were also considered and can include fishponds and rock check dams for flood risk and habitat creation. However, these measures did not provide reduced flood risk for any frequency events where there was capacity in the stream. These measures will be screen from further consideration.
95	Increase governmental funding	Watershed Wide	Increase funding across local, state, and federal sources to cumulatively work to improve coverage of forest restoration, invasive species control, and other green infrastructure projects. Increase collaboration between government entities.	Reforestation	Screened Out	Increasing funding across local, state, and federal sources is outside the scope of USACE's study authority.
96	Debris basins	Upper Watershed	Install debris basins to collect debris in the upper watershed before it clogs up the Ala Wai canal.	Debris Management	Screened Out	Debris catchment structures were evaluated throughout the watershed within the main stream channel and were determined to increase flood risk. Therefore, catchment structures will be screened from the evaluation as a standalone measure, but will be considered during the design of recommended flood risk management features, e.g. bypasses, drainage structures, etc. This study will consider options to reduce the impact of flooding due to buildup of debris by considering modifications to stream channels and structures such as bridges. Recommendations may also be made to address the root causes of debris buildup such as invasive species control, restoration of native plantings, and setbacks.
97	Bridge bypass and debris	Upper Watershed	Spot treatment to low spots along the streams - debris screening and emergency bypasses or spillways for each bridge in the valleys so that the waters don't raise and erode neighboring properties.	Bypass	Retained	Flood risk management measures within the selected plan will include debris catchment/deterent features to prevent the buildup and blockage of debris. Bridge modifications and bypasses are also being explored.
98	Detention basins	Upper Watershed	Detention basins in government lands in mauka conservation districts if the City will maintain it. There is not enough width and depth in the existing flood channels to accommodate a large flood.	Dams	Screened Out	Previous hydraulic modeling has shown detention basins within the upper watershed to be relatively ineffective at reducing downstream flooding--both extent and depth. Previous modeling indicates that the benefits of these detention basins are localized due to significant inflow sources throughout the watershed--a pattern expected to occur for all flood events. The cost of the detention basins, as described in both the feasibility and validation reports, are higher than features that more effectively reduce downstream flood risk. The combination of high costs and low benefits is indicative of a potentially low benefit-to-cost ratio; thus, it is unlikely that the detention basins would be economically justified. Furthermore, dams would present an incremental risk to the downstream community and would have significant environmental impacts to environmental resources within the conservation districts.

Tracking #	Measure Name	Basin	Description	Type	Status	Notes/Rationale
99	Reduce waterfront hotels for green pathways	Lower Watershed	Reduce the number of coastal hotels along Waikiki beach and create green pathways from the Ala Wai and open space where water can flow from mauka to makai.	Impervious Surface Reduction	Screened Out	The study will consider nonstructural measures, such as acquisition and relocation. See measure #184. Relocations must follow standards set forth under the The Uniform Relocation Assistance and Real Property Acquisition Act. Relocation of coastal properties within Waikiki would be very costly, especially with the real estate constraints within the watershed.
100	Flood zone construction requirements	Lower Watershed	Require new buildings in Waikiki to be built resilient to floods (e.g. open ground level and permeable surfaces)	Nonstructural	Screened Out	Changing local community zoning regulations is outside the scope of USACE's study authority. However, as part of the study USACE can make recommendations related to zoning for local communities to implement.
101	Storage tunnels	Watershed Wide	Utilize large, deep vertical tunnels to store stormwater throughout the watershed.	Detention	Screened Out	Concepts of this measure are included in #66. Given the highly karst subsurface, drastic slope variability, and limited open space for vertical tunnel construction, this measure will be screened from further consideration.
102	Diversion tunnels	Watershed Wide	Construct tunnels that can serve as a dual purpose to convey floodwaters in large storm events and can also be used as transportation (or other utility) infrastructure.	Tunnel/Conduit	Screened Out	Components and concepts of this measure are included in #66 and are similar to #45. Consequently, this measure is being screened from further considertion as a stand-alone measure. The team will consider multiuse functionality in the design, if a tunnel is justifiable; however, transportation features would be considered betterments and could not be cost shared with the federal government.
103	Replicate Tokyo's water discharge tunnel system	Watershed Wide	Replicate Tokyo's water discharge tunnel system	Tunnel/Conduit	Screened Out	A system that mirrors Tokyo's water discharge system (approximately $3B to construct) is likely not to be justified as costs are likely to exceed benefits. Components and concepts of this measure are included in #66.
104	Reduce hardcover and impervious surfaces	Watershed Wide	Limit and reduce hardcover in the urban environment that increase runoff. Remove impervious surfaces and replace with porous surfaces.	Impervious Surface Reduction	Screened Out	Modeling indicates that although this measure would help reduce surface water runoff, the minimal reductions in downstream flood risk are not enough to justify the initial and ongoing maintenance costs. It should also be noted that permeable pavement could present maintenance challenges for the City.
105	Educate homeowners of proper disposal	Watershed Wide	Educate homeowners on proper disposal of cuttings and logs	Nonstructural	Screened Out	Educating community members of their role in reducing flood risk is incorporated in measure #186. This includes proper disposal of debris/trash and stream maintenance. This measure will be screened out for redundancy.
106	Educate homeowners of stream maintenance responsibilities	Watershed Wide	Educate homeowners who live along the stream of their responsibility to properly maintain the stream within their property	Nonstructural	Screened Out	Educating community members of their role in reducing flood risk is incorporated in measure #186. This includes proper disposal of debris/trash and stream maintenance. This measure will be screened out for redundancy.
107	Increase maintenance funding	Watershed Wide	Use the State's portion of what they committed to the project ($120M) towards maintenance and programs to get rid of the causes of debris.	Debris Management	Screened Out	Increasing funding across local, state, and federal sources is outside the scope of USACE's study authority. This study will consider options to reduce the impact of flooding due to buildup of debris by considering modifications to stream channels and structures such as bridges, as well as measures that address the root causes of debris buildup such as invasive species control, restoration of native plantings, and setbacks.
108	Replicate Kaori Sanctuary for watershed restoration	Watershed Wide	Look to replicating the Karori Sanctuary near Wellington, NZ as a model of a successful watershed restoration project to implement in the Ala Wai watershed ecosystem. The project would involve removing all of the invasive alien species such as the Albizia, the wild pigs, the alien stream species such as the armored catfish, etc. and then replanting with species that are more compatible with the native Hawaiian watershed ecosystem, stabilizing the stream banks with native plants, fencing the entire upper watershed so that the wild pigs once removed from the area cannot re-invade the area, etc. This is the source of the problems that impacts everything else downstream into the canal down into Waikiki. Addressing issues up mauka will mitigate much of the larger issues faced today in the lower watershed.	Reforestation	Screened Out	This study will assess the ability of natural and nature-based measures, including many of those listed here (i.e., non-native species management, watershed management), to reduce downstream flood risk. The team will model and assess the efficacy of these measures using approved technical approaches. However, the study authority is limited with respect to stream bank stabilization (see notes on measure 84) and wildlife management (see notes on measure 93). Components and concepts of this measure are included in #65. This measure will be screened out for redundancy.
109	Develop a plan for clearing & maintaining the forest and streams	Watershed Wide	Develop a plan for clearing and maintaining the forest and streams. The plan can include increased frequency of maintenance, and will need to be updated for future conditions.	Reforestation	Screened Out	Concepts of this measure are included in #65 (forest management). Channel clearing and modification can be incorporated into the study. However, long-term clearing programs or periodic stream cleanups cannot be included in a recommended plan as it is outside of the authority of USACE to partner in ongoing maintenance efforts. The study can include the recommendation to develop or re-evaluate a comprehensive debris management plan (see response to measure #188). This measure is screened out for redundancy.
110	Clear overgrown vegetation	Watershed Wide	Clear the overgrown vegetation from the streams.	Debris Management	Screened Out	Channel clearing and modification can be incorporated into the study (see measure #96 and 168). However, USACE would not be engaged in long-term operation and maintenance. A debris management plan can be recommended, such as in measure #188. This measure will be screened out for redundancy as components and concepts of this measure are seen in the previously mentioned measures (#96, 168, and 188).
111	Natural retention areas	Watershed Wide	Plant trees, mulching areas, large underground retention areas (storage tanks). A way of controlling volume of stormwater. Our current infrastructure is concrete, which doesn't allow for water to naturally percolate into aquifer. Green infrastructure would retain, restore, possibly filter water to a more manageable degree.	Detention	Screened Out	Concepts of this measure are included in #104, #86, and #87, which address reduction of impervious surfaces and underground detention. This measure is screened out for redundancy.
112	Create wetland terraces	Watershed Wide	bring the 'aina back to its natural state – bring back the lo'i and flooded wetland terraces, return water to the aquifers	Wetland/Floodplain	Screened Out	Components and concepts of this measure are included in measure #94. This measure will be screened out for redundancy.

Tracking #	Measure Name	Basin	Description	Type	Status	Notes/Rationale
113	Put laws in place for water retention	Watershed Wide	Put laws into place to mandate homeowners retain water on their property for use at a later time, e.g. rain barrels, rain gardens, bioswales.	Nonstructural	Screened Out	Changing local community regulations and laws is outside the scope of the USACE study. The study could make recommendations for nonstructural measures, including rain barrels; however, participation would not be mandatory.
114	Incorporate traditional use and practices	Watershed Wide	Request for considerations for traditional use and practices to be incorporated within the redesign and improvements of the Ala Wai. For example the retention at the golf course presents an opportunity to reconnect the history of Waikiki and its sprouting fresh water that sustained kalo fields up until the construction of the canal and full-fledged sale of Waikiki to the business interests of large, primarily foreign land owners. Preserve the rights of present and future generations in the waters of the state to include Maoli rights and practices, such as kalo cultivation.	Wetland/Floodplain	Screened Out	This study focuses on flood risk management, incorporating traditional use and practices will be considered as part of the Section 106 process. Components and concepts of this measure are included in measure #94. This measure will be screened out for redundancy.
115	Establish a Special Drainage and Urban Forest District	Watershed Wide	The whole urbanized Ala Wai Watershed above the canal needs to explicitly become a part of the solution. The city should establish and landowners should support a "Special Drainage and Urban Forest District", analogous to the Special Districts established in the 1970s for Diamond Head, Waikiki, the State Capitol area, Chinatown, etc. These were established to preserve green open space, views and historic structures. Runoff has substantially increased by added urbanization in the middle reaches the past 100 years. Most recently the situation has been exacerbated by the proliferation of "monster houses" that literally roof and pave most of their property, adding runoff to the storm drains along with other issues. Typically they replaced much smaller houses surrounded by gardens. It seems like "Forest restoration" limited to the mauka conservation zone.	Nonstructural	Screened Out	Establishment of such a district is outside the USACE study scope. However, components of this measure, such as reduction of impervious surfaces and hardcover, are included in #104.
116	Netherlands approach to flood mitigation	Watershed Wide	Follow approaches done in the Netherlands, using a holistic approach to address flooding. https://www.earthmagazine.org/article/dutch-masters-netherlands-exports-flood-control-expertise/ Space can be allocated to safely accommodate flooding. Dikes and other obstructions are removed, and flood channels and floodplains are broadened and deepened.	Channel Modification	Screened Out	Components and concepts of this measure are included in measures that investigate wetlands (#94), natural floodplains, and channel modifications (#168, #146, #5, etc.). The final recommended plan will be holistic in nature. This measure will be screened out for redundancy.
117	Improve existing stormwater drainage system	Watershed Wide	Make improvements to the existing stormwater drainage system, such as increasing conduit size or adding additional drainage in areas prone to flooding	Tunnel/Conduit	Screened Out	Provision, modification, and/or maintenance of drainage systems to capture and convey interior runoff in urban areas is a non-Federal responsibility and therefore cannot be included in a recommendation made as a result of this general reevaluation report. However, this study can make modifications to natural stream channels or previously modified natural waterways that help reduce backup within adjacent drainage systems. This study will also be considering modification of existing storm systems as a means for underground bypass channels, see #134.
118	Bridge modification	Watershed Wide	Modify by raising or widening bridges that act as choke points, such as the bridges at Woodlawn Drive, Kahaloa, Lowery, East Manoa, and Kapiolani Blvd.	Bridge Modification	Retained	All pinch points within the system will be investigated for bridge modfication to increase conveyance. This measure will be retained until more conclusive flood risk management impacts at specific locations are identified, screened, or retained.
119	Convert excess water from liquid to steam	Ala Wai Canal	Change the excess water from liquid to steam by having a small opening in the canal at the height that you don't want the water to go above, and to have this on the Mauka side of the canal. The opening would be small, 2'x2', with a metal grate on the opening like graph paper to prevent fish or other animals from entering and the water would lead to a big stove top like structure with holes in the ground above it leading to the surface to let out the steam. The device would heat up, either automatically by using sensors, or by a switch, so if the water gets too high, the device will heat the water that comes in, turn it to steam, and lower the water in the canal. It would have to be on the Mauka side so the steam can be released without anyone near it so no one gets hurt.	N/A	Screened Out	Measure is not technically feasible and poses a safety risk to the community and the environment.
120	Implement permeable pavement	Watershed Wide	Replace impervious pavement with permeable pavement on roads throughout the watershed to help with aquifer recharge.	Impervious Surface Reduction	Screened Out	Components and concepts of this measure are included in measure #104. This measure will be screened out for redundancy.
121	Regular maintenance at high risk areas	Watershed Wide	DFM should be adequately funded to provide full-time dedicated maintenance at all flood risk areas. For example, in Manoa, the Woodlawn Bridge often builds up with debris, plants growing on dirt and "silt bars" as does under the Kahaloa Bridge, despite it being concrete padded several years ago. Also, existing debris catchments such as that behind Palolo Elementary are not well maintained.	Debris Management	Screened Out	Increasing funding across local, state, and federal sources is outside the scope of USACE's study authority. However, there maybe a way to address debris within the design of other project features (#96) or with the recommendation of the development of a long-term debris management plan (see response to measure #188).
122	Early flood warning system	Watershed Wide	Early flood warning system to alert communities of impending floods	Nonstructural	Screened Out	Components and concepts of this measure are included in #185. This measure will be screened out for redundancy.

Tracking #	Measure Name	Basin	Description	Type	Status	Notes/Rationale
123	Green space for detention to reduce TMDLs	Watershed Wide	C&C of Honolulu's Dept of Environmental Services (ENV) has programs in place to reduce TMDLs in critical watersheds to meet stormwater permit conditions with the State Dept of Health/EPA. Consider maximizing the use of available green/park spaces to develop storm water detention/regulation (e.g. when drainage networks are adjacent to parks and can be readily redirected). ENV can work in collaboration with the CORPS for small win-wins.	Detention	Screened Out	Detention will be investigated at various green spaces within the watershed. The main purpose, however, is not to reduce TMDLs - it is to reduce flood risk to the community as per the study authorization. Detention (such as measures #172, 173, 138, and85) and debris basins (such as measure #96) could inherently result in mutliple benefits such as reducing TMDLs. This measure will be screened out for redundancy, as all green spaces are being explored for detention.
124	Loi kalo and ahupuaa system	Watershed Wide	consider the Lo'i kalo and ahupuaa system	Wetland/Floodplain	Screened Out	Components and concepts of this measure are included in measure #94. This measure will be screened out for redundancy.
125	Do nothing	Watershed Wide	Let it flood and federal government continues to provide funds to assist in clean-up efforts	No Action	Retained	
126	Basement parking structure detention	Watershed Wide	Convert or create basement parking structures within the watershed into underground detention (multiuse underground parking)	Detention	Screened Out	Above ground storage solutions are of the highest priority. The amount of storage available above ground is generally greater than storage capacity available under ground for cost-effective solutions. Additionally, the karst subsurface conditions pose challenges for underground storage. The cost required for real estate and construction methods are generally much higher for under ground storage solutions. All storage solutions for basement parking have been determined to have insufficient storage for flood risk management. This measure will be screened from further consideration.
127	Subsurface Woodlawn Tunnel	Manoa	Subsurface tunnel from Woodlawn Bridge to the harbor using gravity flow	Tunnel/Conduit	Screened Out	Components and concepts of this measure are included in #55 and 66. This measure will be screened out for redundancy.
128	Berm around Innovation Center	Manoa	Build a berm in the parking lot of the Innovation Center to capture overflow waters from Manoa Stream and divert water back into stream downstream of Woodlawn Bridge	Floodwall/Berm	Screened Out	Components and concepts of this measure are included in #71 and #175. The design of the detention area (i.e. storage volume and berm height) will be based on the amount of storage needed to reduce waters overtopping the bank at Woodlawn Bridge. A bypass at the bridge will also be explored. This measure will be screened out for redundancy.
129	Increase stream capacity	Manoa	Widen the stream or build floodwalls to increase stream capacity near the Woodlawn Bridge	Channel Modification	Screened Out	Increasing capacity of the channel with a modification or with floodwalls is captured under measure 168 and 176, respectively. This measure will be screened out for redundancy.
130	Piikoi Bypass	Makiki	Utilize or upgrade existing storm sewer to route water from Kanaha Stream to Ala Moana Park	Bypass	Retained	The analysis from measure #134 will help determine sizing and number of culverts needed to upgrade the existing storm sewer system. The technical team will continue to determine the best layout, inlet, and outlet connections for this concept.
131	Pensacola Bypass	Makiki	Utilize or upgrade existing storm sewer to route water from Kanaha Stream to Ala Moana Park	Bypass	Screened Out	Components and concepts of this measure are included in measure #130. Upgrading the existing storm sewer system to convey flow to Ala Moana Park will be based on infrastructure, utilities, and conveyance efficiency. This measure has been screened out for redundancy.
132	Ke'eaumoku Bypass	Makiki	Utilize or upgrade existing storm sewer to route water from Kanaha Stream to Ala Moana Park	Bypass	Screened Out	Components and concepts of this measure are included in measure #130. Upgrading the existing storm sewer system to convey flow to Ala Moana Park will be based on infrastructure, utilities, and conveyance efficiency. This measure has been screened out for redundancy.
133	Young Bypass	Makiki	Utilize or upgrade existing storm sewer to route water from Makiki Stream to Ala Wai Harbor	Bypass	Screened Out	This measure has been screened out after determining that this culvert has an indirect route to the harbor and is downstream of much of the modeled flooding. The Piikoi Bypass (measure #130) has more conveyance and would have a more direct route to Ala Moana Park where flows would discharge.
134	Makiki Tunnel System	Makiki	Tunnel System with Storage (can outlet to harbor and/or release with pumps); Inflow from Kanaha at Makiki District Park	Tunnel/Conduit	Retained	Each tunnel investigated will incorporate land use, environmental impacts, and inflow to determine the location and size of tunnels. Results from the analysis will also help determine sizing of upgrading existing infrastructure (see measure #130), if viable.
135	Stevenson Middle School Playing Fields Detention Pond	Makiki	Approximately 14 ac-ft of storage near Kanaha Stream headwater	Detention	Screened Out	Screened out since measure would provide engineering challenges with the drastic elevation change between the stream and the playing fields.
136	Roosevelt High School Football Fields Detention Pond	Makiki	Approximately 6 ac-ft of storage near Kanaha Stream headwaters	Detention	Screened Out	Screened out since measure would provide engineering challenges with the drastic elevation change between the stream and the playing fields.
137	Archie Baker Park Detention Pond	Makiki	Approximately 1 acre of surface; Unsure of depth for storage due to terrain; Near Makiki Stream headwaters	Detention	Screened Out	Screened out since measure unlikely to capture significant floodwaters. Additional engineering challenges with the drastic elevation change between the stream and the park.
138	Makiki District Park and Tennis Courts Detention Pond	Makiki	Approximately 13 ac-ft of storage at confluence of Kanaha and Makiki Streams	Detention	Retained	Modeling efforts have deemed this measure to be technically feasible and efficient. This measure will be carried forward in the study process.
139	Cartwright Neighborhood Park Detention Pond	Makiki	Approximately 5 ac-ft of storage near Makiki Stream, downstream of confluence with Kanaha	Detention	Screened Out	Screened out due to limited storage space and challenges with inlet/outlet connections due to distance from stream.
140	Central Union Church Lot Detention Pond	Makiki	Approximately 2.8 ac-ft of storage east of Makiki Stream, downstream of confluence with Kanaha	Detention	Screened Out	Screened from consideration since unlikely to be effective due to small storage size and distance from stream.
141	Washington Middle School Detention Pond	Makiki	Approximately 1.5 ac-ft of storage east of Makiki Stream, downstream of confluence with Kanaha	Detention	Screened Out	Screened from consideration since unlikely to be effective due to small storage size, distance from the stream, and existing flooding in the vicinity.
142	Punahou School Detention Pond	Makiki	Approximately 22 ac-ft of storage east of confluence with Kanaha and Makiki Stream	Detention	Screened Out	Due to location and elevation changes in this area, storage in this location is unlikely to be effective.

Tracking #	Measure Name	Basin	Description	Type	Status	Notes/Rationale
143	Daylight streams	Makiki	Daylight streams at constrictions - will need hydraulic results to identify pinch points	Channel Naturalization	Retained	The hydraulic modeling has determined the potential need and benefit to convert underground culverts to daylighted streams in order to increase conveyance of the system. Further considerations for this measure include real estate acquisition and infrastructure impacts.
144	Ala Moana Park Underground Storage	Makiki	Underground Storage in conjunction with Bypass measure; storage not expected to be an efficient measure otherwise	Detention	Screened Out	This measure is screened out due to the technical complexity of underground storage in an area with high buoyant forces. However, the team will include above ground storage in conjunction with a bypass to retain water and mitigate for induced flooding at the tidally influenced downstream outlet, if said measure of a bypass (#130) is retained.
145	Modify bridges	Watershed Wide	Modify bridges at constrictions - will need hydraulic results to identify pinch points	Bridge Modification	Screened Out	Components and concepts of this measure are included in measure #118. This measure is screened out for redundancy.
146	Palolo Channel Modification	Palolo	Deepen or widen channel to provide more within-bank storage; can be used in conjunction with channel naturalization	Channel Modification	Screened Out	Modeling results indicate that channel modification along Palolo Stream near Palolo Valley District Park has a negligible reduction in flood risk to the local and downstream neighborhood. This measure is screend from further evaluation.
147	Palolo Channel Naturalization	Palolo	Return channel to a more natural state by removing concrete and adding natural slope material. This measure will likely be in conjunction with channel deepening, upstream detention and/or bridge modification to offset increased water elevations. Naturalization will reduce velocities and dampen peak flow.	Channel Naturalization	Screened Out	Naturalizing the channel along Palolo stream would cause higher water surface elevations in an area that already has flooding. Naturalizing would reduce conveyance in order to maintain proper side slopes for natural material. To maintain conveyance, extensive real estate would be required. This measure is screened from further evaluation.
148	Ali'iolani Elementary School Detention Pond	Palolo	Approximately 0.7 ac-ft of storage southeast of Palolo Stream	Detention	Screened Out	Screened from consideration since unlikely to be effective due to small storage size and distance from stream.
149	William P. Jarrett Middle School Detention Pond	Palolo	Approximately 0.7 ac-ft of storage near Palolo downstream of the Pukele and Waiomao confluence	Detention	Screened Out	Screened from consideration since unlikely to be effective due to small storage size and difference in elevation between the stream and play fields.
150	Pālolo Valley District Park Detention Pond	Palolo	Approximately 15 ac-ft of storage near Palolo downstream of the Pukele and Waiomao confluence	Detention	Screened Out	Components and concepts of this measure are included in measure #85. This measure is screened out for redundancy.
151	Pālolo Elementary School Detention Pond	Palolo	Approximately 0.9 ac-ft of storage near Waiomao just upstream of the Pukele and Waiomao confluence	Detention	Screened Out	Screened from consideration since unlikely to be effective due to small storage size and elevation difference between the stream and the playing fields.
152	Pālolo Valley Homes Detention Pond	Palolo	Approximately 6.5 ac-ft of storage near Waiomao just upstream of the Pukele and Waiomao confluence	Detention	Screened Out	Screened from consideration due to elevation difference in elevation between the stream and potential storage area. Also potential environmental consideration with extensive removal of trees.
153	Kula Kaiapuni 'O Ānuenue Detention Pond	Palolo	Approximately 0.7 ac-ft of storage near Pukele upstream of the Pukele and Waiomao confluence	Detention	Screened Out	Screened from consideration since unlikely to be effective due to small storage size and difference in elevation between the stream and play fields.
154	Lā-'ī Rd Detention Pond	Palolo	Approximately 3 ac-ft of storage near headwaters of Pukele	Detention	Screened Out	Screened from consideration due to elevation difference in elevation between the stream and potential storage area. Also potential environmental consideration with extensive removal of trees.
155	Public Storage Parking Lot Detention Pond	Palolo	Approximately 0.5 ac-ft of storage above the confluence of the Manoa - Palolo Canal	Detention	Screened Out	Screened from consideration since unlikely to be effective due to small storage size.
156	City Mill Parking Lot Detention Pond	Palolo	Approximately 0.7 ac-ft of storage above the confluence of the Manoa - Palolo Canal	Detention	Screened Out	Screened from consideration since unlikely to be effective due to small storage size
157	Palolo Stilling Basin(s)	Palolo	Stilling Basin to dissipate energy and reduce velocities from channelized stream - will need hydraulic results to identify areas of high velocities with minimal upstream impacts	Grade Control Structure	Screened Out	Palolo stream does not have capacity for stilling basins or other grade control structures. Any structure that will slow down water will also increase water surface elevations in an area that already floods. This measure is screened from further consideration.
158	Permeable Pavement System at Public Storage Parking Lot	Palolo	Replace parking lot with permeable pavement to reduce direct runoff above the confluence	Impervious Surface Reduction	Screened Out	Components and concepts of this measure are included in measure #104. This measure will be screened out for redundancy.
159	Permeable Pavement System at City Mill Parking Lot	Palolo	Replace parking lot with permeable pavement to reduce direct runoff above the confluence	Impervious Surface Reduction	Screened Out	Components and concepts of this measure are included in measure #104. This measure will be screened out for redundancy.
160	Permeable Pavement System at Pālolo Hongwanji Mission	Palolo	Replace parking lot with permeable pavement to reduce direct runoff	Impervious Surface Reduction	Screened Out	Components and concepts of this measure are included in measure #104. This measure will be screened out for redundancy.
161	Palolo Tunnel System	Palolo	Tunnel System with Storage (can outlet to ocean using gravity); Inflow from Waiomao and Pukele at confluence (2/3 of system flow); Additional basin inflow does not have ideal entrance location	Tunnel/Conduit	Screened Out	Components and concepts of this measure are included in #66 (SWIFT Tunnels). Each tunnel investigated in the Palolo subbasin will incorporate land use, environmental impacts, and inflow to determine the location and size of tunnels. Detention at Palolo District Park is being investigated first to reduce flows within the Palolo stream. This measure will be screened out for redundancy.
162	St. Louis High School Football Field Underground Storage	Palolo	Underground detention structure below playing fields of the school; storage capacity not yet determined	Detention	Screened Out	Due to location and elevation changes in this area, storage in this location is unlikely to be effective and costs are likely to exceed benefits.
163	Pālolo Valley District Park Underground Storage	Palolo	Underground detention structure below park; storage capacity not yet determined	Detention	Screened Out	Components and concepts of this measure are included in measure #85. This measure is screened out for redundancy.
164	Public Storage Parking Lot Underground Storage	Palolo	Underground detention structure below parking lot; storage capacity not yet determined	Detention	Screened Out	Components and concepts of this measure are included in #86. This measure will be screened out for redundancy.
165	City Mill Parking Lot Underground Storage	Palolo	Underground detention structure below parking lot; storage capacity not yet determined	Detention	Screened Out	Components and concepts of this measure are included in #86. This measure will be screened out for redundancy.
166	Woodlawn Bridge Modification	Manoa	Raise bridge to prevent debris buildup	Bridge Modification	Screened Out	Components and concepts of this measure are included in measure #118. This measure is screened out for redundancy.
167	Woodlawn Drive Bypass	Manoa	Capture overflow water from Woodlawn Drive and return to stream	Bypass	Retained	A bypass at Woodlawn Drive bridge will be considered as a standalone measure and in combination with other measures at Woodlawn Drive.
168	Manoa Channel Modification	Manoa	Deepen/Widen channel to provide more within-bank storage	Channel Modification	Retained	Channel modification along Manoa Stream near Woodlawn has been retained. Other areas along Manoa are still under consideration.

Tracking #	Measure Name	Basin	Description	Type	Status	Notes/Rationale
169	Manoa Channel Naturalization at Bridge Highway near E Manoa Rd	Manoa	Return channel to a more natural state by removing concrete and bridge highway; replace with natural slope material	Channel Naturalization	Screened Out	Components and concepts of this measure are included in #170. This measure will be screened out for redundancy.
170	Manoa Channel Naturalization below Manoa Valley District Park	Manoa	Return channel to a more natural state by removing concrete and adding natural slope material. This measure will likely be in conjunction with channel deepening, upstream detention and/or floodwalls. Naturalization will reduce velocities and dampen peak flow at Woodlawn.	Channel Naturalization	Screened Out	Naturalizing the channel between Manoa Park and Woodlawn Bridge would cause higher water surface elevations in an area that already has flooding. Naturalizing would reduce conveyance in order to maintain proper side slopes for natural material. To maintain conveyance, extensive real estate would be required.
171	Manoa Channelization	Manoa	Channelize the stream to reduce peak flows at Woodlawn	Channel Modification	Screened Out	Channelizing would adversely impact natural stream habitat, will increase flows, and will reduce response time from peak rainfall to peak flood.
172	Manoa Valley District Park Detention Pond	Manoa	Approximately 33.5 ac-ft of storage on the right bank of Manoa Stream	Detention	Retained	Modeling efforts have deemed this measure to be technically feasible and efficient. This measure will be carried forward in the study process.
173	Kanewai Detention Pond	Manoa	Approximately 4.5 ac-ft of storage on the right bank of Manoa Stream	Detention	Screened Out	Modeling considered type and amount of storage needed, where/how to get water to the basin, and where/how to outlet the water (i.e., directly back to channel, conduit to harbor or golf course). Considerations also included the community floodwall and the nearby school. It was determined that above ground storage at Kanewai did not provide the anticipated flood risk reduction. This measure will be screened from further evaluation. Underground storage at Kanewai Park is being considered under measure #181.
174	University of Hawaii Practice Fields Detention Pond	Manoa	Approximately 19 ac-ft of storage on the right bank of Manoa Stream near UH	Detention	Screened Out	This measure poses technical challenges with drilling through a mountain to pipe water in, grading, and associated costs of excavation. This area is associated with karst geology, resulting in additional challenges and risks.
175	Manoa Innovation Center Floodplain/Parking Lot Storage	Manoa	Use natural floodplain/parking lot to contain flood waters and store water	Detention	Screened Out	Floodplain storage is already utilized by local interior drainage and overbank flooding. No additional capacity is available. This measure has been screened out. Other measures will be explored in the Woodlawn Bridge area.
176	Woodlawn Bridge Floodwall	Manoa	Floodwall (permanent or deployable) at Woodlawn Drive Bridge vicinity to contain water to channel	Floodwall/Berm	Retained	This measure increases channel conveyance and will be evaluated in combination with channel modifications, bridge modification, bypasses, and detention.
177	Koali Rd Floodwall	Manoa	Floodwall along left bank of Manoa Stream, downstream of Kanewai Community Park to protect community from upstream peak flows	Floodwall/Berm	Retained	This measure will be retained with the understanding of the current community floodwall at Kanewai Park. Considerations include space availability, bedrock, and existing channel retaining wall loadings.
178	University of Hawaii Deployable Floodwall	Manoa	System of deployable floodwall around the UH Campus	Floodwall/Berm	Screened Out	A system of deployable floodwalls around the campus may cause higher water surface elevations in neighboring communities. Instead, the team will focus on the source of flooding at Woodlawn bridge. However, non-structural measures will be considered on a structure-by-structure basis (measure #184).
179	Permeable Pavement System at Manoa Marketplace Parking Lot	Manoa	Replace parking lot with permeable pavement to reduce direct runoff contributing to flows down Woodlawn Drive	Impervious Surface Reduction	Screened Out	Components and concepts of this measure are included in measure #104. This measure will be screened out for redundancy.
180	Manoa Tunnel System	Manoa	Tunnel System with Storage (can outlet to ocean using gravity); detention basin and tunnel from Manoa Valley District Park; approx. 2/3 of flow is in the system at this location; Additional basin inflow does not have ideal entrance location	Tunnel/Conduit	Screened Out	Components and concepts of this measure are included in #55 and 66. This measure will be screened out for redundancy.
181	Kanewai Underground Storage	Manoa	Underground detention structure below park; storage capacity not yet determined	Detention	Retained	This measure will be further evaluated given that above ground storage at Kanewai Community Park (#173) did not provide sufficient flood risk management benefits. Below ground storage is considerably more expensive than above ground. The team is actively working on developing storage capacity calculations and cost estimates for this measure.
182	Manoa Marketplace Underground Storage	Manoa	Underground detention structure below parking lot; storage capacity not yet determined	Detention	Screened Out	Components and concepts of this measure are included in #86. This measure will be screened out for redundancy.
183	State Land of Kalaepohaku Ridge Underground Detention	Manoa	Large underground storage tank on the embankment of the Kalaepohaku Ridge	Detention	Screened Out	Real Estate aquisition and engineering challenges to use the base of a mountain side as storage. The team will consider other storage options within this basin.
184	Physical non-structural measures	Watershed Wide	Nonstructural measures are permanent or contingent measures applied to a structure and/or its contents that prevent or provide resistance to damage from flooding. Measures can include elevation, relocation, acquisition, dry flood proofing, or wet flood proofing.	Nonstructural	Retained	Potential for nonstructural measures (e.g., elevation, floodproofing, relocation, flood warning systems) will be assessed once economic models are finalized.
185	Flood Warning System	Watershed Wide	Flood Warning Systems alert citizens in flood prone areas of impending high water, giving the opportunity to evacuate damageable property and themselves from flood-prone areas.	Nonstructural	Retained	
186	Risk Communication/Education	Watershed Wide	Risk Communication develops and uses educational tools such as presentations, workshops, hand-outs, and pamphlets to communicate flood risk and flood risk reduction measures.	Nonstructural	Retained	
187	Emergency Preparedness Plans	Watershed Wide	Develop and maintain a flood emergency preparedness plan that identifies hazards, risks and vulnerabilities, and encourages the development of local mitigation. Plans should include the community's response to flooding, location of evacuation centers, evacuation routes, and flood recovery processes.	Nonstructural	Retained	

Tracking #	Measure Name	Basin	Description	Type	Status	Notes/Rationale
188	Debris Management Plan	Watershed Wide	A comprehensive debris management plan that outlines a strategy to efficiently and effectively remove and dispose of debris on a maintenance schedule or after a storm would reduce blockages at constrictions in rivers and therefore reduce flood levels at those constrictions.	Debris Management	Screened Out	Maintenance of privately-owned portions of each stream is the responsibility of the individual landowner(s). The City and County of Honolulu Department of Facility Maintenance is responsible for maintaining portions of each streams that flows onto public property. This study will consider options to reduce the impact of flooding due to buildup of debris by considering modifications to stream channels and structures such as bridges, as well as measures that address the root causes of debris buildup such as invasive species control, restoration of native plantings, and setbacks. This study will not include long term dredging, maintenance, or periodic stream cleanups as a part of the recommended plan as it is outside of the authority of the Corps to partner in ongoing maintenance efforts. However, the study can include the recommendation to develop or re-evaluate a comprehensive debris management plan.
189	Ala Wai Canal Tunnel	Ala Wai Canal	Underground tunnel to outlet into the ocean; serves as a second outlet to the canal	Tunnel/Conduit	Screened Out	Components and concepts of this measure are included in #20 and 22. This measure will be screened out for redundancy.
190	Paki Ave Bypass	Ala Wai Canal	Utilize existing storm sewer system along Paki Ave as a bypass for Ala Wai Canal waters; Outfall is away from the highly traveled beach and tourist area; Existing outfall near Tahitienne Condos of Honolulu	Bypass	Screened Out	Utilizing or upgrading the existing storm sewer infrastructure to a larger and appropriate culvert size did not provide adequate flood risk management impacts in or around the Ala Wai Canal during the hydraulic modeling analysis. This measure will be screened from further consideration.
191	Leahi Ave Bypass	Ala Wai Canal	Utilize existing storm sewer system along Leahi Ave as a bypass for Ala Wai Canal waters; Outfall is away from the highly traveled beach and tourist area; Existing outfall near Tahitienne Condos of Honolulu	Bypass	Screened Out	Concepts and components of this measure are included in measure #190. The final layout will be coordinated with the City and will be determined based on available capacity and existing infrastructure. This measure will be screened out for redundancy.
192	H1 Underground Storage System	Lower Watershed	Series of underground detention basins along the H1 highway	Detention	Screened Out	The amount of storage needed to contain flood waters is not achieveable with the limited space along or under the highway. Underground storage along the H-1 interstate could also adversely affect structural stability for the highway foundation/piers.
193	Ala Wai Canal Floodwall System	Ala Wai Canal	Series of new floodwalls on the left and right banks of the Ala Wai canal and M-P canal; design considerations could include road closure structures and access for the canoes; deployable/passive system, glass system to keep viewshed, or aesthetically acceptable (e.g. lava rock wall) design will be considered.	Floodwall/Berm	Retained	This measure will be modeled with the understanding of flow regimes and sea level rise at the canal.
194	Manoa-Palolo Diversion Structure	Lower Watershed	Diversion structure downstream of the Date Street bridge that diverts flows for a design storm to the Ala Wai Golf Course; In combination with berms around the golf course to increase storage.	Detention	Screened Out	Components and concepts of this measure are included in measure #39. This measure is screened out for redundancy.
195	Ala Wai Golf Course Berm	Ala Wai Canal	Berms in strategic locations to increase above-ground flood storage; can be used in combination with diversion structure	Floodwall/Berm	Screened Out	Components and concepts of this measure are included in measure #39. This measure is screened out for redundancy.
196	Ala Wai Canal Surge Barrier	Ala Wai Canal	Surge barrier/Flood gates to reduce impacts from tide and increase storage in canal; pump station in conjunction with floodwalls along canal to increase storage capacity	Gates	Retained	Placement, size, and type of flood gates will be determined based on inflow, channel geometry, flood storage, and waterway usage. A surge barrier will not be evaluated due to its intended use of storm surge protection. Analyses have determined that storm surges do not historically relate to inland rain events for this watershed. However, floodgates in conjunction with floodwalls and a pump station will still be evaluated to address riverine flooding.
197	Ala Wai Canal Pump Station(s)	Ala Wai Canal	Pump or system of smaller pumps along the canal to reduce standing water or used in conjunction with floodwalls/berms to increase storage capacity	Pumps	Retained	Placement, size, and type of pump will be determined based on inflow and land use, including interior drainage impacts due to flood risk management features part of the selected plan.
198	Ala Wai Canal Deepening	Ala Wai Canal	Dredge canal to an appropriate depth to increase storage capacity and maintain slope/structural integrity	Channel Modification	Screened Out	Dredging to the maintenance elevation is encouraged for the City to maintain consistently. Deepening the canal further than the maintenance elevation is generally not recommended due to the stability of canal walls and slope stability. Increasing storage of the canal can technically reduce flooding but not without instability of the structural components of the bridges and canal walls. The integrity of the canal walls as-is would not withstand excavation - only replacing with an entirely new system would. Further analysis is needed to determine the stability of bridge pier and footings. See measure 5.
199	Cool Ala Wai	Ala Wai Canal	Plan includes forest restoration in upper watershed; converting golf course to wetlands on the lower 2/3 and residential housing on the upper 1/3; gate structures at the golf course inlet and Manoa-Palolo to control the flow of water into the canal; gate structure at mouth of canal to address sea level rise and storm surge; mimic the Singapore Marina Barrage for urban reservoir design, https://www.youtube.com/watch?v=4WA2sR6pBRo	Wetland/Floodplain	Screened Out	Rezoning residential housing is outside the scope of this project. Individual components of this plan have been addressed in other measures within this spreadsheet. See measures #65 for forest management, #39 for wetlands and diversion structure at the golf course, and #196 for gate structure at the mouth. This measure is screened out for redundancy.
200	Portable flood barriers	Watershed Wide	Portable flood barriers, https://www.youtube.com/watch?v=dQjqFPKh01s	Floodwall/Berm	Screened Out	In the simulation (video), they were able to divert flood waters (ankle-deep) across 6 meters within 5 minutes. This system can hold back water up to 0.5 meters in height. The flashy nature of the watershed would not provide much time for crews to set up these barriers, let alone safely. It may provide protection for more frequent (smaller) storm events but would not provide a viable solution for flood greater than 1.5 ft. This is a great option for individual homeowners or businessowners. These structures, however, do not meet USACE requirements for structural integrity or safety.

Tracking #	Measure Name	Basin	Description	Type	Status	Notes/Rationale
201	Palolo diversion channel	Palolo	The water from the Palolo Valley should go straight into the Ocean parallel to Kapahulu Avenue and be decoupled from the Manoa-Palolo Canal (that is a major old design mistake that exacerbates the current risk of flooding).	Channel Modification	Screened Out	Decoupling of the river system to a daylighted stream parallel to Kapahulu would require extensive land/property acquisition and would have negative impacts to the marine and nearshore environment. The team will investigate other means to reduce flood risk, such as tunnels (#161), detention (#85), bypasses, and channel deepening (#146).
202	Ala Wai Green	Ala Wai Canal	A bio-diverse, multi-function natural resource park. The Ala Wai Green would occupy the ewa 2/3 of the closed golf course. Restore the former wetlands and serve as a natural retention basin for the collection of rainwater from the valleys in a complex of reservoirs, ponds, and waterways. Debris, soil runoff and pollutants from upstream would be removed after passing through a series of gates and a multi-stage filtration system before entering into the Ala Wai canal.	Wetland/Floodplain	Screened Out	Components and concepts of this measure are included in measure #38 and #39. This measure is screened out for redundancy.
203	Overflow ditches parallel to the Ala Wai Canal	Ala Wai Canal	Construct overflow ditches parallel to the Ala Wai Canal (see diagram) on the Mauka (Mountain) side. Within the ditch, construct water jets at the bottom and sensors along the walls of the ditch. A grill would cover the ditch for safety and some sort of screen to prevent debris from falling into the ditch. Prior to the storm, screens would be removed to allow maximum over flow water to enter the ditches.	Detention	Screened Out	This measure as described would not be an ideal solution, although innovative. The sensors, jets, and ditches would need a high level of continuous maintenance for efficiency. Removing debris grates prior to the storm would not work as intended because of the high volume of debris that passes during a storm event. The debris could also cause damage to the sensors and jets. Additionally, there are safety concerns of having a maintenance crew removing grates prior to a storm given the extreme flashy nature of flood events in the basin. The concept of ditches to increase storage will be carried forward as part of detention measures #32 & #39. The concept of ditches as part of conveyance measures are carried forward under #20, 21, 22, and 55. The concept of pumps (jets) to push water out or remove stagnant water will be carried forward within measure #197.
204	Filter Strips	Ala Wai Canal	Filter strips that reduce erosion and nitrate contaminates for high rainfall event. (Potentially use Kernza plant)	Water Quality	Screened Out	Best management practices, such as filter strips, to reduce runoff and improve water quality are outside the USACE study authority. However, natural and nature-based flood risk management measures will be evaluated, which can also improve water quality and reduce erosion as secondary benefits. See measure #94 for incorporating traditional practices in a flood risk management solution.
205	Kalawahine Reservoir	Makiki	Existing ponding basin located on Kapahu and Anianiku St. (Kapo'opo'o and Kanahā Stream)	Detention	Screened Out	Kalawahine Reservoir is an active project. The land is reserved for construction of a 2MG reservoir for water supply by the Board of Water Supply. The nearby ponding basin cannot be used for storage, as it will not provide meaninful storage to reduce flood risk downstream.
206	Palolo floodwalls	Palolo	Raise existing floodwalls higher to contain more water	Floodwall/Berm	Screened Out	Floodwalls along Palolo stream would require extensive real estate acquisition and easements from properties along the channel. The construction and real estate costs of this measure greatly outweigh the damages reduced. This measure is screened from further evaluation.
207	City Mill culvert	Palolo	Utilize the culvert next to City Mill to slow down or detain water; culvert is 15' deep in this area.	Detention	Screened Out	Utilizing or upgrading the existing storm sewer infrastructure to a larger and appropriate culvert size did not provide adequate flood risk management impacts in or around Palolo Stream during the hydraulic modeling analysis. This measure will be screened from further consideration.
208	Palolo pipe within culverts	Palolo	Lay a pipe within the existing culverts to evacuate water directly out to sea	Tunnel/Conduit	Screened Out	Under a similar analysis to measure #207, adding, utilizing, or upgrading the existing storm sewer infrastructure to a larger and appropriate culvert size did not provide adequate flood risk management impacts in or around Palolo Stream during the hydraulic modeling analysis. This measure will be screened from further consideration.
209	Redetention	Watershed Wide	2 or more detention basins in series	Detention	Screened Out	Redetention can increase storage in a system or series of detention ponds. However, fo this watershed, there was not a particularly viable location with ample space and appropriate elevation change that would support redetention. This measure will be screened from futher analysis.
210	Berm around all schools	Watershed Wide	Build a 3 ft tall berm around all schools: Iolani School, Ala Wai Elementary, Noelani Elementary, and Hokulani Elementary	Floodwall/Berm	Retained	This measure will be considered after evaluating the residual risk to the schools and surrounding vulnerable communities. Berms around Iolani School and Ala Wai Elementary will be evaluated as part of a floodwall system for the canal (#193). Kaimuki High School is also being considered under measure #53. Non-structural measures will also be considered on a structure-by-structure basis.
211	SWIFT tunnels with outlet at harbor	Watershed Wide	SWIFT tunnels in Manoa and Palolo that outlet into the harbor instead of the ocean. This outlet will be dual functioned as a pier/loading dock for canoe paddlers.	Tunnel/Conduit	Screened Out	Components and concepts of this measure are included in #66, #55, and #161. Recreational use of the project will be coordinated with the City. This measure will be screened out for redundancy.
212	Makiki SWIFT Tunnel	Makiki	SWIFT tunnel from Roosevelt High School down Piikoi to the Ala Wai Harbor. Another alternative location could be near Nehoa St and Makiki St.	Tunnel/Conduit	Screened Out	Components and concepts of this measure are included in measure #134. This measure will be screened out for redundancy.
213	Modify Palolo Stream entry angle	Palolo	Modify the angle that the Palolo Stream intercepts the Manoa Stream with a diverter or other channel modification. The 90 degree angle disrupts Manoa stream flow.	Channel Modification	Screened Out	The results from the Makiki entry angle analysis (measure #64) has determined that the efficiency of this type of channel modification doesn not reduce flooding near the confluence of streams. Considerations for screening also include real estate acquisition. This measure will be screened from further consideration.
214	Kalaimoku St Bypass	Ala Wai Canal	Utilize existing storm sewer system along Kalaimoku St. down Saratoga Rd. as a bypass for Ala Wai Canal waters (above a certain elevation); Can consider other existing storm utilities perpendicular to the canal	Bypass	Screened Out	Components and concepts of this measure are included in measures #20 and #22. This measure will be screened out for redundancy.

Tracking #	Measure Name	Basin	Description	Type	Status	Notes/Rationale
215	Happy Valley Underground Stormwater Storage	Ala Wai Canal	Multifunctional underground storm water detention beneath Ala Wai Golf Course; Flood waters can be repurposed. Hong Kong's Happy Valley Underground Stormwater Storage Scheme: https://www.dsd.gov.hk/EN/Files/Technical_Manual/technical_papers/DP1201.pdf	Detention	Screened Out	Components and concepts of this measure are included in measure #45 and #126. This measure is screened out for redundancy. Flood water repurposing after a storm is outside the scope of this project but will be coordinated with the City and other government offices for multidisciplinary collaboration.
216	University of Hawaii Tunnel	Manoa	Pipe floodwaters from the UH dormitory basketball court area to the Ala Wai Golf Course or out to the harbor	Tunnel/Conduit	Screened Out	Components and concepts of this measure are included in #55. This measure will be screened out for redundancy.
217	St. Louis School Tunnel	Palolo	Pipe floodwaters from Palolo Stream near the St. Louis School football field to the Ala Wai Golf Course or out to the harbor	Tunnel/Conduit	Screened Out	Components and concepts of this measure are included in #66. This measure will be screened out for redundancy.
218	Manoa Park Tunnel	Manoa	Pipe floodwaters from Manoa Stream near Manoa Valley District Park to the Ala Wai Golf Course or out to the harbor	Tunnel/Conduit	Screened Out	Components and concepts of this measure are included in #55. This measure will be screened out for redundancy.
219	Floodgate and bypass or floodgate and pump at Makiki Confluence	Makiki	If floodwalls around the canal are necessary, include a floodgate with bypass or a floodgate with pump at the Makiki Stream confluence to reduce backup to interior drainage along Makiki Stream.	Pumps	Screened Out	This measure will be considered as part of the Ala Wai Canal Floodwall (#193), and as standalone measures near the canal as described in measure #196 (floodgate) and #210 (pumps). This measure will be screened for redundancy.
220	Underground Parking structures along waterways	Ala Wai Canal	Construct underground parking structures along the canal which can be used for flood protection. A parking structure next to Iolani could be used by the school and replace and supplement existing parking along the canal.	Detention	Screened Out	Components and concepts of this measure are included in measure #126. This measure is screened out for redundancy.
221	Waihi Stream detention	Manoa	Create runoff holding facilities along Waihi Stream (near Paradise Park) that could also generate power for C&C as well as potable water.	Detention	Screened Out	Components and concepts of this measure are included in measure #98. This measure will be screened out for redundancy.
222	Biofilter floodwaters for potable water	Watershed Wide	Biofilter floodwaters from parks and open green spaces and use as potable water via Board of Water Supply. Use the energy in daily runoff to pump water into neighborhood water towers; partner with large apartment buildings by funding pumps and holding tanks of potable water in exchange for maintenance in perpetuity.	Water Quality	Screened Out	Detention will be investigated at various green spaces within the watershed. Detention could inherently result in mutliple benefits, including improving water quality and aquifer recharge. Flood water repurposing after a storm is outside the scope of this project but will be coordinated with the City and other government offices for multidisciplinary collaboration. This measure will be screened out for redundancy, as all green spaces are being explored for detention. This includes but is not limited to measures #172, #173, #138, and #85.
223	Enclose canal and build Rail atop canal	Ala Wai Canal	Completely enclose the Ala Wai from Kalakaua all the way to the University of Hawaii and run the rail from Ala Moana to UH on the surface of the enclosed canal.	N/A	Screened Out	This measure was screened because it would have negative implications to flood risk and debris, in addition to life safety. Restricting the canal reduces flood capacity and increases water surface elevations upstream of the enclosed portion. It creates the perfect conditions for debris build-up, which would be difficult to maintain and will exacerbate flooding. In addition, enclosing the canal reduces access to the stream for emergency responders in the event of an emergency or safety threat. Finally, construction of a light rail system is outide the scope and authority of the current USACE study.

Ala Wai Canal Flood Risk Management General Reevaluation Study

Plan Formulation Tracker Workbook

December 2022

Note: The Plan Formulation Tracker is the successor to the Management Measure Tracking Spreadsheet. The intent of this tracker is to share the latest proposed array of alternative plans, to provide an overview of the progression of alternatives through the plan formulation process, and to provide insight into the technical process. A proposed final array of alternatives is contained within this workbook which was identified using standard agency practices and analyses. Public input is welcome and will be accounted for before finalizing the final array of alternatives.

Should you have any questions about the Plan Formulation Tracker, please email AlaWai@honolulu.gov or contact us through the project website at https://www.honolulu.gov/alawai/contact.html

PLAN FORMULATION TRACKER WORKBOOK OVERVIEW

TRACKER UPDATED:	December 8, 2022

PAGE BORDER COLOR	DESCRIPTION
Workbook Explanation	Blue-colored pages are informational and explain various parts of this workbook.
Alternative Retained	Alternative pages in green indicate that this alternative is proposed to be retained.
Alternatives to be Removed	Alternative pages in amber indicate that this alternative will be removed from the array (i.e., dropped from further consideration).

PAGE NAME	PAGE NO.	DESCRIPTION
Workbook Overview	1	A description of all pages contained within this workbook.
Glossary of Alternatives	2	A list of alternatives with descriptions. The proposed final array of alternatives is identified on this page.
How to Read Alternative Tabs	3	An explanation on how to read the Alternative Formulation Progression pages.
Alternative 0	4	An overview of the alternative formulation progression of the No Action Plan.
Alternative 1	5	An overview of the alternative formulation progression of the Storage Plan.
Alternative 2	2A - 6	An overview of the alternative formulation progression of the Conveyance Plan.
	2B - 7	
	2C - 8	
Alternative 3	9	An overview of the alternative formulation progression of the Tunnel Plan.
Alternative 4	10	An overview of the alternative formulation progression of the Natural and Nature-Based Plan.
Alternative 5	11	An overview of the alternative formulation progression of the Hybrid plan.
Definition of Measures	12	A list of measures that were considered when formulating alternatives with definitions. This page also indicates whether measures have been retained or screened.

GLOSSARY OF ALTERNATIVES

ALTERNATIVE	DESCRIPTION	RETAINED
Alternative 0	No action plan.	✓
Alternative 1	A plan that focuses on reducing flood risk throughout the watershed by increasing storage.	✓
Alternative 2A	A plan that focuses on reducing flood risk throughout the watershed by increasing conveyance using existing infrastructure.	
Alternative 2B	A plan that focuses on reducing flood risk throughout the watershed by increasing conveyance using floodwalls at various locations.	✓
Alternative 2C	A plan that focuses on reducing flood risk throughout the watershed by increasing conveyance using a second outlet for the Ala Wai Canal.	
Alternative 3	A plan that focuses on reducing flood risk throughout the watershed by implementing subsurface tunnels.	
Alternative 4	A plan that focuses on reducing flood risk throughout the watershed by using natural and nature-based features, with an emphasis on watershed management.	
Alternative 5	A plan that focuses on reducing flood risk throughout the watershed by utilizing various cornerstones from other plans. This is the hybrid alternative.	✓

Identifies which alternative is being examined within this sheet.

ALTERNATIVE X - EXAMPLE PLAN

Indicates whether the alternative has been retained or will be screened out. If the alternative has been retained, the latest iteration of alterantive formulation is identified. If the alternative will be screened out, a brief explanation is provided.

STATUS: Retained in the final array of alternatives (Alternative X.2)

Second alternative formulation iteration of Alternative X.

MEASURES	ALTERNATIVE X.1	JUSTIFICATION FOR INITIAL INCLUSION	ALTERNATIVE X.2	JUSTIFICATION FOR CHANGE
Measure #1	✓	Cornerstone. Increases storage in the watershed to reduce flood risk.	✓	
Measure #2	✓	This measure works in conjunction with Measure #1.	✓	
Measure #3	✓	Reduce localized impacts from peak flows.		Measure was screened due to lack of effectiveness in reducing water surface elevations.

A list of measures that were included within this alternative during at least one of the alternative formulation iterations.

This identifies the alternative formulation iteration and which measures were included for that iteration. For example, "Alternative X.1" indicates that this was the first formulation iteration for Alternative X. The progression of alternative formulation is presented from left to right, from the oldest to the newest, respectively.

Disclaimer: Alternative X is not a real alternative and is being used for demonstrative purposes only.

This explains the justification for initially including a measure as part of the

If measures are added or removed after a previous alternative formulation iteration, this explains why.

ALTERNATIVE 0 - NO ACTION PLAN

STATUS:	Retained in the Final Array of Alternatives (Alternative 0).

MEASURES	ALTERNATIVE 0	JUSTIFICATION FOR INITIAL INCLUSION
Do nothing	✓	No action plan is required to be part of the array of alternatives.

ALTERNATIVE 1 - STORAGE PLAN

STATUS: Retained in the Final Array of Alternatives (Alternative 1.4).

MEASURES	ALTERNATIVE 1.1	JUSTIFICATION FOR INITIAL INCLUSION	ALTERNATIVE 1.2	JUSTIFICATION FOR CHANGE	ALTERNATIVE 1.3	JUSTIFICATION FOR CHANGE	ALTERNATIVE 1.4	JUSTIFICATION FOR CHANGE
Makiki District Park Detention	✓	Cornerstone. Increase storage to reduce flood risk in Makiki subbasin.	✓		✓		✓	
Kanaha Floodwall	✓	This measure works in conjunction with Makiki District Park Detention to reduce flood risk in the Makiki subbasin.	✓		✓		✓	
Manoa Valley District Park Detention	✓	Cornerstone. Increase storage to reduce flood risk in Manoa subbasin.	✓		✓		✓	
Ala Wai Golf Course Detention	✓	Cornerstone. Increase storage to reduce flood risk in Ala Wai subbasin.	✓		✓		✓	
Kapiolani Park Detention Basin			✓	Potential opportunity identifed to increase storage in Ala Wai subbasin. Added as cornerstone.		Measure screened due to lack of effectiveness in reducing water surface elevations and concerns associated with an existing high ground water table, historic resources, and economic viability.		
Kaimuki High School Berm/Floodwall	✓	Increase storage and reduce flood risk in lower watershed.	✓		✓		✓	
Daylight Makiki Stream			✓	Identified potential measure to enhance flood risk reduction in Makiki subbasin.	✓			Measure screened out due to lack of effectiveness substantially reducing water surface elevations in the Makiki subbasin. Analyses show an estimated high cost and a lack of capturable economic and life safety benefits across all flood frequencies.
Woodlawn Bridge Floodwall	✓	Reduce overbank flooding from the Manoa stream. Reduce severe inundation in Manoa subbasin.	✓		✓		✓	
Koali Road Floodwall	✓	Reduce impacts from peak flows around Manoa-Palolo confluence.	✓		✓		✓	
Woodlawn Channel Modification	✓	Reduce overbank flooding from the Manoa stream. Reduce severe inundation in Manoa subbasin.		Measure screened due to lack of effectiveness in reducing water surface elevations in Lower Manoa.				
Woodlawn Bridge Modification	✓	Reduce overbank flooding from the Manoa stream. Reduce severe inundation in Manoa subbasin.		Measure screened due to lack of effectiveness in reducing water surface elevations in Lower Manoa.				
Woodlawn Drive Bypass	✓	Reduce overbank flooding from the Manoa stream. Reduce severe inundation in Manoa subbasin.		Measure not expected to compliment cornerstone goal of increasing storage and was removed from this alternative.				
Ala Wai Canal Floodwall	✓	Reduce overbank flooding from the Ala Wai Canal.		Removed from alternative due to analyses estimating high costs and the need to identify the National Economic Development (NED) Plan.				
Palolo Valley District Park Detention	✓	Increase storage to reduce flood risk in Palolo subbasin.		Measure screened due to lack of effectiveness in reducing water surface elevations in Palolo and downstream, in the lower watershed.				
Pumps/other structures (flap gates)	✓	Minimum facility needed for design		Removed from this alternative since these are ancillary features in combination with floodwalls.				
Nonstructural to reduce residual risk	✓	Can be used in lieu of structural measures to reduce flood risk.	✓		✓		✓	

ALTERNATIVE 2A - CONVEYANCE (USING EXISTING INFRASTRUCTURE) PLAN

STATUS: Screened out due to lack of effectiveness at reducing flood risk throughout the watershed. All cornerstone measures were screened out individually; therefore, the alternative is screened out.

MEASURES	ALTERNATIVE 2A.1	JUSTIFICATION FOR INITIAL INCLUSION	ALTERNATIVE 2A.2	JUSTIFICATION FOR CHANGE
Piikoi Bypass	✓	Cornerstone. Increase conveyance to reduce flood risk.		Screened out due to lack of effectiveness in reducing water surface elevations.
Woodlawn Drive Bypass	✓	Cornerstone. Increase conveyance to reduce flood risk.		Screened out due to lack of effectiveness in reducing water surface elevations.
Palolo Culverts	✓	Cornerstone. Increase conveyance to reduce flood risk.		Screened out due to lack of effectiveness in reducing water surface elevations.
Waikiki Bypass	✓	Cornerstone. Increase conveyance to reduce flood risk.		Screened out due to lack of effectiveness in reducing water surface elevations.
Paki Ave Bypass	✓	Cornerstone. Increase conveyance to reduce flood risk.		Screened out due to lack of effectiveness in reducing water surface elevations.
Kanaha Floodwall	✓	Reduce overbank flooding from the Kanaha Ditch/Makiki stream.	✓	
Daylight Makiki Stream	✓	Reduce overbank flooding from the Makiki stream.	✓	
Manoa Valley District Park Detention	✓	Reduce overbank flooding from the Manoa stream.	✓	
Woodlawn Bridge Floodwall	✓	Reduce overbank flooding from the Manoa stream.	✓	
Koali Road Floodwall	✓	Reduce impacts from peak flows around Manoa-Palolo confluence.	✓	
Ala Wai Canal Floodwall	✓	Reduce overbank flooding around the Ala Wai Canal.	✓	
Dredge Ala Wai Canal	✓	Deepen channel to increase conveyance.	✓	
Dredge Manoa-Palolo Canal	✓	Deepen channel to increase conveyance.	✓	
Palolo Channel Modification	✓	Reduce overbank flooding from the Palolo stream.	✓	
Pumps/other structures (flap gates)	✓	Minimum facility needed for design.	✓	
Nonstructural to reduce residual risk	✓	Can be used in lieu of structural measures.	✓	

ALTERNATIVE 2B - CONVEYANCE (USING FLOODWALLS) PLAN

STATUS: Retained in the Final Array of Alternatives (Alternative 2B.3).

MEASURES	ALTERNATIVE 2B.1	JUSTIFICATION FOR INITIAL INCLUSION	ALTERNATIVE 2B.2	JUSTIFICATION FOR CHANGE	ALTERNATIVE 2B.3	JUSTIFICATION FOR CHANGE
Kanaha Floodwall	✓	Cornerstone. Increase conveyance to reduce flood risk.	✓		✓	
Woodlawn Bridge Floodwall	✓	Cornerstone. Increase conveyance to reduce flood risk.	✓		✓	
Koali Road Floodwall	✓	Cornerstone. Increase conveyance to reduce flood risk.	✓		✓	
Ala Wai Canal Floodwall	✓	Cornerstone. Increase conveyance to reduce flood risk.	✓		✓	
Woodlawn Drive Bypass			✓	Opportunity identified to increase conveyance in Manoa stream.		Measure screened due to lack of effectiveness in reducing water surface elevations in Lower Manoa.
Waikiki Bypass	✓	Divert water from Ala Wai Canal to ocean to reduce flood risk in Ala Wai subbasin.		Measure screened due to lack of effectiveness in reducing water surface elevations in the Ala Wai subbasin.		
Ala Wai Canal Tunnel (2nd Outlet)	✓	Increase conyeance to reduce flood risk in the Ala Wai subbasin.		Measure screened due to lack of effectiveness in reducing water surface elevations in the Ala Wai subbasin in combination with analyses estimating high project costs.		
Makiki District Park Detention			✓	Storage location works in conjunction with the Kanaha Floodwall.	✓	
Dredge Ala Wai Canal	✓	Deepen channel to increase conveyance		Measure screened out due to analyses estimating high project costs in addition to environmental concerns and wall stability concerns.		
Dredge Manoa-Palolo Canal	✓	Deepen channel to increase conveyance		Measure screened. The M&P Canal is already dredged to the design depth and flood risk reduction benefits are expected to be minimal from further dredging.		
Pumps/other structures (flap gates)	✓	Minimum facility needed for design	✓		✓	
Nonstructural to reduce residual risk	✓	Can be used in lieu of structural measures.	✓		✓	

ALTERNATIVE 2C - CONVEYANCE (2ND OUTLET) PLAN

STATUS: Screened out due to analyses estimating high project cost. There are also environmental concerns and economic viability concerns.

MEASURES	ALTERNATIVE 2C.1	JUSTIFICATION FOR INITIAL INCLUSION	ALTERNATIVE 2C.2	JUSTIFICATION FOR CHANGE	ALTERNATIVE 2C.3	JUSTIFICATION FOR CHANGE	ALTERNATIVE 2C.4	JUSTIFICATION FOR CHANGE
Daylight Ala Wai Canal (2nd Outlet)	✓	Cornerstone. Increase conveyance in the Ala Wai subbasin.	✓		✓			Measure screened out due to analyses showing high project costs in addition to environmental concerns and economic viability concerns.
Kanaha Floodwall	✓	Contain water within Kanaha Ditch/Makiki stream	✓		✓		✓	
Makiki District Park Detention			✓	Measure added to work in conjunction with the Kanaha Floodwall to help reduce flood risk in the Manoa subbasin.	✓		✓	
Woodlawn Bridge Floodwall	✓	Contain water within Manoa stream	✓		✓		✓	
Woodlawn Channel Modification	✓	Contain water within Manoa stream	✓			Measure screened due to lack of effectiveness in reducing water surface elevations in Lower Manoa.		
Koali Road Floodwall	✓	Protect local community from peak flows	✓		✓		✓	
Ala Wai Canal Floodwall	✓	Contain water within the Ala Wai Canal	✓		✓		✓	
Pumps/other structures (flap gates)	✓	Minimum facility needed for design	✓		✓		✓	
Nonstructural to reduce residual risk	✓	Can be used in lieu of structural measures.	✓		✓		✓	

ALTERNATIVE 3 - TUNNEL PLAN

STATUS: Screened out. Tunnels did not reduce/remove enough water from the system to eliminate damages.The tunnel alternative would still need floodwalls and other measures as well, which is not likely to be economically justified as a system.

MEASURES	ALTERNATIVE 3.1	JUSTIFICATION FOR INITIAL INCLUSION	ALTERNATIVE 3.2	JUSTIFICATION FOR CHANGE	ALTERNATIVE 3.3	JUSTIFICATION FOR CHANGE	ALTERNATIVE 3.4	JUSTIFICATION FOR CHANGE	ALTERNATIVE 3.5	JUSTIFICATION FOR CHANGE	ALTERNATIVE 3.6	JUSTIFICATION FOR CHANGE
Makiki Tunnel	✓	Cornerstone. Reduce flood risk using tunnels.	✓			Measure screened out due to analyses showing high project costs and lack of capturable flood risk reduction benefits.						
SWIFT Tunnel (Manoa)	✓	Cornerstone. Reduce flood risk using tunnels.	✓		✓		✓		✓			Measure screened out due to analyses showing high project costs and lack of capturable flood risk reduction benefits.
SWIFT Tunnel (Palolo)	✓	Cornerstone. Reduce flood risk using tunnels.		Measure screened out due to analyses showing high project costs and lack of capturable flood risk reduction benefits.								
Woodlawn Bridge Floodwall	✓	Reduce overbank flooding from the Manoa stream.	✓		✓		✓		✓		✓	
Ala Wai Canal Floodwall	✓	Reduce overbank flooding from the Ala Wai Canal.	✓		✓		✓			Measure removed from the alternative. High costs for both the floodwalls and tunnel would likely not produce an economically viable plan.		
Ala Wai Golf Course Detention									✓	Added to reduce flood risk in the Ala Wai subbasin after floodwalls were removed from this alternative.	✓	
Piikoi Bypass							✓	Measure added in lieu of Makiki Tunnel measure to reduce flood risk in the Makiki subbasin.		Measure screened due to lack of effectiveness in reducing water surface elevations in Makiki and analysis showing high project cost.		
Pumps/other structures (flap gates)	✓	Minimum facility needed for design	✓		✓		✓			Removed since these are ancillary features in combination with floodwalls.		
Nonstructural to reduce residual risk	✓	Can be used in lieu of structural measures	✓		✓		✓		✓		✓	

ALTERNATIVE 4 - NATURAL AND NATURE-BASED FEATURES (NNBF) PLAN

STATUS: Screened out due to lack of effectiveness at reducing flood risk. Analysis showed a level of flood risk reduction benefits at frequent events, but not at less frequent events. Watershed management will be recommended as a best practice.

MEASURES	ALTERNATIVE 4.1	JUSTIFICATION FOR INITIAL INCLUSION	ALTERNATIVE 4.2	JUSTIFICATION FOR CHANGE	ALTERNATIVE 4.3	JUSTIFICATION FOR CHANGE	ALTERNATIVE 4.4	JUSTIFICATION FOR CHANGE
Watershed Management	✓	Cornerstone. Reduce flood risk using natural and nature-based features.	✓		✓			Measure screened due to lack of effectiveness at reducing flood risk. While there is some benefit, it is not expected to be enough to justify this measure.
Makiki District Park Detention	✓	Increase storage to reduce flood risk in Makiki subbasin.	✓		✓		✓	
Kanaha Floodwall	✓	The Kanaha Floodwall works in conjunction with the Makiki District Park Detention to reduce flood risk in the Makiki subbasin.	✓		✓		✓	
Manoa Valley District Park Detention	✓	Reduce overbank flooding from the Manoa stream and increase local storage.	✓		✓		✓	
Woodlawn Bridge Floodwall	✓	Reduce overbank flooding from the Manoa stream. Reduce severe inundation in Manoa subbasin.	✓		✓		✓	
Koali Road Floodwall	✓	Reduce impacts from peak flows around Manoa-Palolo confluence.	✓		✓		✓	
Palolo Valley District Park Detention	✓	Increase storage in Palolo subbasin.		Measure screened due to lack of effectiveness in reducing water surface elevations in Palolo and downstream in the lower watershed.				
Dredge Manoa-Palolo Canal	✓	Dredge canal to increase conveyance.		Measure screened. The M&P Canal is already dredged to the design depth and flood risk reduction benefits are expected to be minimal.				
Kaimuki High School Berm/Floodwall	✓	Increase storage and reduce flood risk in lower watershed.	✓		✓		✓	
Ala Wai Golf Course Detention	✓	Increase storage in the lower watershed.	✓		✓		✓	
Ala Wai Canal Floodwall	✓	Reduce overbank flooding around the Ala Wai Canal.	✓			Measure removed from alternative to emphasize natural and nature-based features and for National Economic Development (NED) plan identification purposes.		
Piikoi Bypass	✓	Reduce flood risk in Makiki subbasin by routing flows from Kanaha Stream to Ala Moana Park.		Measure screened due to lack of effectiveness in reducing water surface elevations in Makiki and analysis showing high project cost.				
Woodlawn Drive Bypass	✓	Reduce overbank flooding from the Manoa stream. Reduce severe inundation in Manoa subbasin.	✓		✓		✓	
Woodlawn Channel Modification	✓	Reduce overbank flooding from the Manoa stream. Reduce severe inundation in Manoa subbasin.	✓			Measure removed from alternative because it is not necessary to implement with the Woodlawn Drive Bypass in place.		
Palolo Channel Modification	✓	Reduce overbank flooding from the Palolo stream.		Measure screened due to lack of effectiveness in reducing water surface elevations in Palolo.				
Daylight Makiki Stream			✓	Potential to enhance flood risk reduction in Makiki subbasin.	✓		✓	
Pumps/other structures (flap gates)	✓	Minimum facility needed for design.	✓		✓		✓	
Nonstructural to reduce residual risk	✓	Can be used in lieu of structural measures.	✓		✓		✓	

ALTERNATIVE 5 - HYBRID PLAN

STATUS: Retained in the Final Array of Alternatives (Alternative 5.4).

MEASURES	ALTERNATIVE 5.1	JUSTIFICATION FOR INITIAL INCLUSION	ALTERNATIVE 5.2	JUSTIFICATION FOR CHANGE	ALTERNATIVE 5.3	JUSTIFICATION FOR CHANGE	ALTERNATIVE 5.4	JUSTIFICATION FOR CHANGE
Manoa Valley District Park Detention	✓	Cornerstone. Reduce flood risk using various cornerstones from other plans.	✓		✓		✓	
Woodlawn Drive Bypass	✓	Cornerstone. Reduce flood risk using various cornerstones from other plans.	✓		✓			Measure screened due to lack of effectiveness in water surface elevations in Lower Manoa.
Ala Wai Canal Floodwall	✓	Cornerstone. Reduce flood risk using various cornerstones from other plans.	✓		✓		✓	
Woodlawn Bridge Floodwall	✓	Reduce overbank flooding from the Manoa stream. Reduce severe inundation in Manoa subbasin.	✓		✓		✓	
Koali Road Floodwall	✓	Reduce impacts from peak flows around Manoa-Palolo confluence.	✓		✓		✓	
Makiki District Park Detention	✓	Increase storage to reduce flood risk in Makiki subbasin.	✓		✓		✓	
Kanaha Floodwall	✓	The Kanaha Floodwall works in conjunction with the Makiki District Park Detention to reduce flood risk in the Makiki subbasin.	✓		✓		✓	
Palolo Channel Modification	✓	Reduce overbank flooding from the Palolo stream.		Measure screened due to lack of effectiveness in reducing water surface elevations in Palolo.				
Piikoi Bypass			✓	Potential opportunity identified to reduce flood risk in Makiki subbasin.		Screened out due to lack of effectiveness in reducing water surface elevations.		
Ala Wai Golf Course Detention			✓	Potential opportunity identified to reduce flood risk using detention in conjunction with floodwalls.	✓		✓	
Dredge Ala Wai Canal			✓	Potential opportunity to reduce flood risk in lower watershed. Compliments Ala Wai Canal floodwall.		Measure screened due analyses showing high cost in addition to environmental concerns and wall stability concerns.		
Woodlawn Channel Modification					✓	Opportunity to implement this measure instead of Woodlawn Drive Bypass.		Measure screened due to lack of effectiveness in reducing water surface elevations in Lower Manoa.
Pumps/other structures (flap gates)	✓	Minimum facility needed for design.	✓		✓		✓	
Nonstructural to reduce residual risk	✓	Can be used in lieu of structural measures.	✓		✓		✓	

DEFINITION OF MEASURES

MEASURE	Measure #	DEFINITION	Retained
Ala Wai Canal Floodgate	**196**	Floodgate (not surge barrier) with pumps located at the mouth of canal for the purpose of addressing local runoff. This measure was analyzed for implementation into an alternative but was determined to not be able to operate (ramp up) at the rate that flooding is expected to occur in near the canal. The measure included a pump system that was not economically feasible for the anticiapted flow.	
Ala Wai Canal Floodwall	**193**	Floodwall system along the Ala Wai Canal (Mauka and Makai) that may extend up the Manoa-Palolo canal and Makiki Stream.	✓
Ala Wai Canal Tunnel (2nd Outlet)	**22**	Eastern end of canal will be extended via subsurface tunnel as a second outlet to the ocean.	
Ala Wai Golf Course Detention	**39**	Design the Ala Wai Golf Course to include berm features for increased storage near the canal.	✓
Berm around schools	**210**	A berm around schools within the watershed will be considered after evaluating the residual risk to the schools and surrounding vulnerable communities. Berms around Iolani School and Ala Wai Elementary will be evaluated as part of a floodwall system for the canal (#193). Kaimuki High School is also being considered under measure #53. Non-structural measures will also be considered on a structure-by-structure basis (#184).	✓
Bridge bypasses and debris screening	**97**	Flood risk management measures within the selected plan will include debris catchment/deterent features to prevent the buildup and blockage of debris.	✓
Daylight Ala Wai Canal (2nd Outlet)	**21**	Eastern end of canal will be extended via daylighting as a second outlet to the ocean.	
Daylight Makiki Stream	**143**	Increasing conveyance and reducing restrictions along Makiki Stream by opening up culverts via daylighting.	
Do nothing	**125**	No action.	✓
Dredge Ala Wai Canal	**5**	Ala Wai Canal will be dredged to its design depth or acceptable level of dredging, considering environmental impacts, slope stability, and structural integrity of the canal walls.	
Dredge Manoa-Palolo Canal	**8**	Dredge Manoa-Palolo Canal to increase storage and conveyance from Palolo and Manoa.	
Kaimuki High School Berm/Floodwall	**53**	This measure will be considered both as an extention of the Ala Wai Canal floodwall on the Manoa-Palolo Canal and as a levee/floodwall in the playing fields of the Kaimuki High School to protect the community and school behind the levee, as a standalone measure.	✓
Kanaha Floodwall	**224**	Floodwall on the Kanaha Stream where water jumps bank due to low terrain and flows towards Lower Makiki and Ala Moana.	✓
Kanewai Underground Storage	**181**	A detention basin (underground and above ground) at the Kanewai Community Park was explored. This measure was analyzed for implementation into the alternative but was determined to not be feasible. Above ground storage did not provide significant flood management. Below ground detention provided less benefits than that of above ground. A combination of below and above ground was also explored, and was determined to not be feasible due to the forces involved.	
Kapiolani Park Detention Basin	**59**	Divert water to Kapiolani Park for additional flood storage.	
Koali Road Floodwall	**177**	Floodwall along the Manoa and Palolo Streams along Koali Rd, downstream of Kanewai Park.	✓
Makiki District Park Detention	**138**	Makiki District Park multi-purpose detention pond.	✓
Makiki Tunnel	**134**	Subsurface tunnel diverting water from the headwaters of the Makiki Stream to the harbor or ocean.	
Manoa Valley District Park Detention	**172**	Manoa Valley District Park multi-purpose detention pond.	✓
Waikiki Bypass	**20**	Utilize existing storm sewer system or add bypasses from the Ala Wai Canal through Waikiki to the ocean to increase conveyance.	
Nonstructural Measures	**184**	Nonstructural measures are permanent or contingent measures applied to a structure and/or its contents that prevent or provide resistance to damage from flooding. Nonstructural measures can also include non-physical flood risk management, such as emergency preparedness plans, risk communication and education, and flood warning systems.	✓
Paki Ave Bypass	**190**	Utilize existing storm sewer system along Paki Ave as a bypass for Ala Wai Canal waters.	
Palolo Channel Modification	**146**	Deepen or widen channel to provide more within-bank storage; can be used in conjunction with channel naturalization.	
Palolo Culverts	**207**	Bypass from Palolo Stream along Kapahulu Ave to Waikiki Wall outfall by upgrading existing storm sewer infrastructure with a double barrel culvert.	
Palolo Valley District Park Detention	**85**	Palolo Valley District Park multi-purpose detention pond.	
Piikoi Street Bypass	**130**	Bypass from Kanaha Stream down Piikoi Street to Ala Moana Park by upgrading/utilizing existing storm sewer infrastructure.	
Pumps/other structures (flap gates)	**80**	Pumps and other structures, such as flap gates on storm drains, that are needed to reduce interior drainage impacts from other measures within the alternative, such as floodwalls. Minimum facility required to implement certain measures.	✓
SWIFT Tunnel (Manoa)	**66**	Subsurface tunnel diverting water from the headwaters of the Manoa Stream to the harbor or ocean.	
SWIFT Tunnel (Palolo)	**66**	Subsurface tunnel diverting water from the headwaters of the Palolo Stream to the harbor or ocean.	
Watershed Management	**65**	Watershed Management includes removing invasive species and replanting with native species to restore the canopy and root system; controlling ungulate to reduce destruction of vegetation by wild/feral animals; and reducing hardcover/non-porous surfaces in the urban environment to decrease runoff. This measure will be recommended as a best practice.	
Woodlawn Bridge Floodwall	**176**	Floodwall along Manoa Stream at Woodlawn Drive bridge.	✓
Woodlawn Bridge Modification	**118**	Modify the bridge at Woodlawn Drive to increase conveyance.	
Woodlawn Channel Modification	**168**	Channel modification along Manoa Stream near Woodlawn Drive bridge.	
Woodlawn Drive Bypass	**167**	Bypass of Manoa Stream at Woodlawn Drive by constructing new inlet and upgrading/utilizing existing storm water infrastructure.

ADDENDUM A Ala Wai Canal Flood Risk Management Study, Final Feasibility Study Report with Integrated Environmental Impact Statement, Appendix A Hydrology and Hydraulic Engineering (2017 Feasibility Study, H&H Appendix)

ADDENDUM B Hydrology Report, Ala Wai Canal Modeling Effort (2021 Validation Study)

ADDENDUM C Hydraulics Report, Ala Wai Canal Modeling Effort (2021 Validation Study)

ADDENDUM D December 6-8 , 2021 Rainfall Event on Ala Wai Watershed

ADDENDUM E Watershed Measures Analysis Flow Summary

1. Introduction

This Ala Wai Flood Risk Management (FRM) General Reevaluation Study is authorized as a traditional flood risk management study to determine potential mitigation measures that can address flooding damages as a result of watershed runoff from high-precipitation events. The objective of the Ala Wai Canal FRM Project is to reduce riverine flood risks in the Ala Wai Watershed.

The study authority is Section 209 of the Flood Control Act of 1962 (Public Law 87-874) and Section 216 of the Flood Control Act of 1970, as amended. The study authorization is the Supplemental Appropriations of the Bipartisan Budget Act of 2018 (Public Law 115-123). The project would protect metropolitan Honolulu, the University of Hawaii, and Waikiki, Hawaii's economic center for tourism. The population at risk includes approximately 65,000 residents and an additional 200,000 transient visitors to the watershed daily (tourists, workers, students, etc.).

1.1. Frequency Storm nomenclature

Evaluations of consequences and benefits are based upon design storm amounts which, based upon statistical analysis of historical precipitation events and distributions, have a probable chance of being exceeded in any given year. The events are thus termed as having an annual exceedance probability, or AEP, often as a percentage. Using this nomenclature is deemed to more clearly emphasize the likelihood of an event occurring as a probability as opposed to a frequency or cycle; e.g., the terminology for what was commonly referred to as the "100-year" event can be misconstrued as only occurring once in 100 years, while in fact the event that has a 1 in 100 (or 1%) chance of happening each year and does not typically occur in a one-hundred-year cycle. To the extent feasible, effort has been made to refer to storm events used in the analysis relative to their percentage AEP, but for clarity, Table 1-1 is provided to demonstrate the equivalency of events, regardless of terminology used.

Table 1-1: Equivalent Frequency Terms

99% AEP	0.99 AEP	"1 Year Event"
50% AEP	0.5 AEP	"2 Year Event"
20% AEP	0.2 AEP	"5 Year Event"
10% AEP	0.1 AEP	"10 Year Event"
5% AEP	0.05 AEP	"20 Year Event"
2% AEP	0.02 AEP	"50 Year Event"
1% AEP	0.01 AEP	"100 Year Event"
0.5% AEP	0.005 AEP	"200 Year Event"
0.2% AEP	0.002 AEP	"500 Year Event"

1.2. Study History

The Ala Wai Flood Risk Management project started as a Feasibility Study in 2017 and is documented in "Ala Wai Canal Flood Risk Management Study O'ahu, Hawai'i Final Feasibility Study Report with integrated Environmental Impact Statement Appendix A – Hydrology and Engineering (2017)". The results of the Feasibility study were questioned due to the uncertainty associated with the 1D steady state hydraulic model that was used.

A Post-Feasibility study was initiated to update the steady state 1D HECRAS model from the previous study with 2D areas for the overland areas and to switch to unsteady flow to improve the accuracy of the model. Once the updated model was updated and calibrated, the features from the Feasibility Study tentatively selected plan (TSP) were input to determine their impact and then modifications to the features were evaluated. Information on that can be found in the "Ala Wai Flood Risk Management Project, Honolulu, Hawaii, Engineering Documentation Report, July 16, 2020" which led to changes in the authorized project based on the updated hydrologic and hydraulic engineering ("H&H") assumptions (1D/2D Unsteady State hydraulic model).

A Validation study to reexamine the project justification, economics, and environmental effects from modifications to authorized project features as described in the 2017 Feasibility Report. The H&H analyses and results are documented in the "Ala Wai Flood Risk Management Project, Honolulu, Hawaii, Validation Report, Appendix A - Hydrology and Hydraulic Analysis, March 25, 2021". The validation study only focused on the 1% annual exceedance probability (AEP), and the study led to no recommended plan.

This General Reevaluation Study is set to look at all flood events and is not constrained to assessing only the 1% AEP flood event for measures which would reduce flooding.

1.3. Hydrologic and Hydraulic Modeling History

The Ala Wai Watershed has been modeled for multiple studies, and there have been numerous versions of hydrologic and hydraulic models constructed for those studies. A more detailed summary of these legacy HEC-HMS and HEC-RAS models can be found in the 2017 Feasibility Study H&H (Addendum A) and in the 2021 Validation Study H&H Appendix, which is included as Addendums B (the Hydrologic Report) and C (the Hydraulic Report) to this Appendix.

1.3.1. Validation Study - Summary of MMC Hydrologic Analysis:

As detailed in Addendum B, the validation study revisited the original hydrologic without-project existing conditions analysis performed in the original Feasibility study. Aside from the realignment of watershed breakpoints to facilitate incorporation of results into the hydraulic modeling, the effort focused on examining and frequency flows, revised through use of the HEC Watershed Analysis Tool (HEC-WAT) Monte-Carlo Analysis tool to randomly select predefined storm templates to apply frequency precipitation on the watershed model. After 60,000 iterations and definition of the uncertainty bounds, the HEC-Statistical Software Package (HEC-SSP) was used to analyze the iteration results and select the maximum peak discharges. A balanced hydrograph shape was applied to the peak flows, and these revised frequency hydrographs were incorporated into the HEC-RAS model (described in more detail below).

1.3.2. Validation Study - Summary of MMC Hydraulic Analysis:

The USACE Modeling, Mapping, and Consequences (MMC) Production Center updated the 1D, steady state hydraulic model developed during the feasibility phase modeled in HEC-RAS version 4.1.0 and advanced it to a 1D/2D unsteady state model with 1D analysis in the stream channels and 2D flow in the overbank areas using HEC-RAS version 5.0.7. The more notable changes to the HEC-RAS model included addition of 2D storage areas in overbanks, incorporation of new terrain data, use of unsteady flow hydrographs, and recalibration to historic storms. A detailed description of the Validation Study model update can be found in Addendum C. A summary of the changes is listed below.

Update model to most recent published version (HEC-RAS Version 5.0.7).
Modify Geometry to include 2-dimensional (2D) areas for the overbanks where needed.
Review bridges, tunnels, and other existing features in previous model.
Incorporate new terrain data and modify in areas where new features will be added.
Incorporate land cover data for 2D roughness values.
Update model to unsteady flow which is needed for 2D modeling.
Re-link model to new HEC-HMS flows as discussed in the Hydrology section.
Calibrate and validate updated model to the 2004, 2006, and 1967 events.
Creation of alternative geometries for project features.
Routing of 100-year frequency with different modified geometries.
Compiling a final report for inclusion with the hydraulics updates.

A single without project geometry was brought forward for the final frequency and uncertainty routings. That was used for the FWOP model runs in the Validation Study. That is also the geometry that was utilized as a base model for this GRR Study.

1.4. Ala Wai Watershed

1.4.1. Watershed Overview

The Ala Wai Watershed study area is 19 square miles and extends from the ridge of the Ko'olau Mountains to the nearshore waters of Mamala Bay and includes drainages of Manoa, Palolo, Maikiki, McCully, Moiliili, and Waikiki Streams. The Manoa and Palolo streams join to form the Manoa-Palolo Canal. The Manoa-Palolo Canal, Makiki Stream, and three low lying drainage areas empty into the Ala Wai Canal, a 2-mile-long, man-made waterway constructed during the 1920s to drain extensive coastal wetlands, thus allowing development of the Waikiki district. The Ala Wai Watershed study area is shown in Figure 1-1.

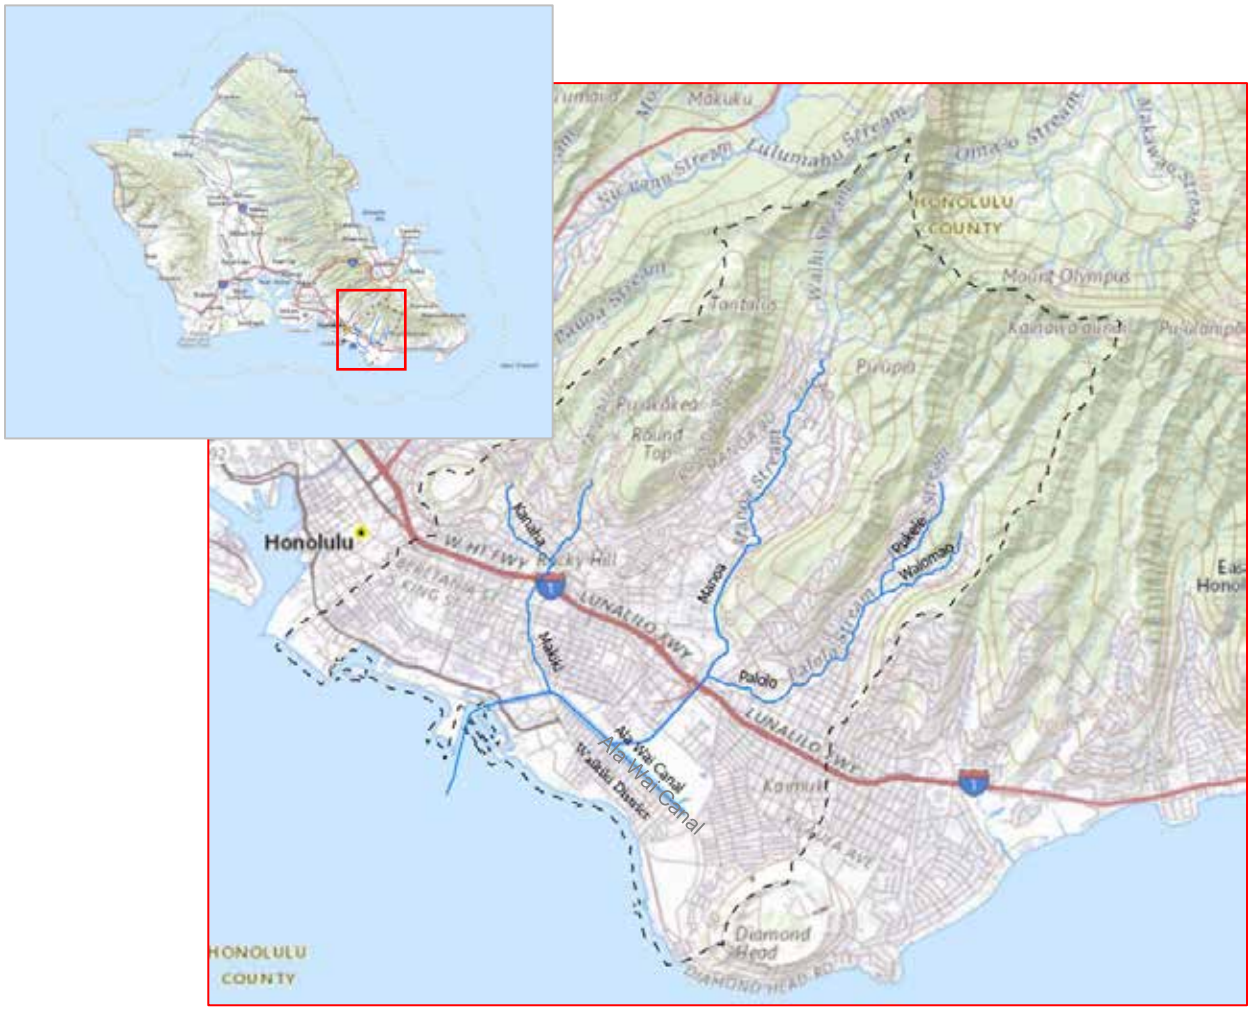

Figure 1-1: Location of Ala Wai Watershed, O‘ahu Hawai’i

The upper reaches of the basin are very steep and rocky and incised into the Ko’olau Volcano. This portion of the watershed ranges from 40 to approximately 2400 feet in elevation [1]. The Makiki and Manoa basins typically receive more than 160 inches of rain annually, while the Palolo valley receives less. The lower portion of the basin is much less steep and is extremely urbanized. Significant portions of the lower watershed are impervious surfaces, with sewer system drainage actively directing most of the runoff in less intense events. The drainage area encompassing Ala Wai Canal and Waikiki receives about 30 inches of annual rainfall. High-Intensity rainfall on steep slopes of the small drainage basin can produce very flashy flood events in the lower basin. Time to peak is usually less than 1 hour and even for large intense storms, the rise and recession of the flood hydrograph usually occurs with 6 hours.

[1] Unless otherwise specified, elevations herein are in feet referencing Local Mean Sea Level (LMSL), Tidal Epoch 1983-2001 (commonly referenced by midpoint date as LMSL 1992).

1.4.2. Historical Context and Weather Phenomenon

The Ala Wai canal overtopped and previously flooded Waikiki during the November 1965 and December 1967 storms, as well as during the passage of Hurricane Iniki in 1992. In October 2004, a storm flooded Manoa Valley, causing $85M in damages to the University of Hawai'i, including the loss of irreplaceable documents in one of the libraries. Additional flooding occurred in March 2006 as part of an extended rain event caused by a developing La Niña pattern (NOAA National Weather Service, 2006). La Niña cycles tend to amplify and extend the winter wet season, creating above normal rainfall and frequency of thunderstorms (Bravender, 2011). Hurricanes have not historically posed a significant threat of headwater flooding from long duration, intense precipitation. Due to the location of the Hawaiian Islands in the Pacific relative to a high-pressure feature to the northeast, large storms are usually deflected or weakened before they approach the region. Cooler waters also play a role in weakening tropical systems that track through the area (Puleo, 2020).

Kona lows are more typical storm events affecting the watershed and the Hawaiian Islands generally. The word "kona" is Hawaiian for "leeward" which means the side of an island that is usually sheltered from prevailing trade winds and associated rainfall; the trade winds typically come from the northeast to east-northeast. Kona lows are subtropical storms that occur during the cool season in the north central Pacific. Historically kona lows bring abundant moisture from the southwest which can produce significant precipitation in multiple forms (e.g., rain, snow, hail) in short time periods, leading to flash flooding and other related storm damages (Mossison & Businger; NOAA NESDIS, 2021).

The Hawaiian Islands are also subjected to extreme astronomical tidal events. King Tides are the highest tides of the year caused by the moon's orbit bringing it closer to Earth than at other times of the year. In the Hawaiian Islands, this generally occurs in July and August and again in December and January in conjunction with new moons and full moons, such that the gravitational forces of the sun and moon are compounded. The timing of these extreme water level events can be anticipated through the use of tidal predictions, yet their impacts can have devastating consequences for coastal inhabitants, particularly when combined with severe weather or high wave events (University of Hawai'i).

2. Hydrology

2.1. Review of MMC model

For this reevaluation effort, H&H Project Delivery Team (PDT) members reviewed the background modeling and the most recent hydrologic model updates conducted by the MMC as part of the Validation study (See paragraph 1.2.1 above). This review affirmed the methodology performed in this most recent analysis as appropriate or exceeding that necessary for the purposes of a establishing the baseline existing conditions, future-without-project (FWOP) conditions and screening of potential mitigation measures and alternatives. The ability to further calibrate the model was limited by minimal gage data for the few significant historical storm events that have affected the watershed. Any additional calibration effort would have required repeating the HEC-WAT Monte Carlo simulation and data processing with minimal (if any)

expected change to peak discharges but would have potential significant schedule impacts. It was determined that the Validation Study results were appropriate for the General Reevaluation Study.

2.2. December 2021 Kona Low

An unusual December storm was experienced throughout Hawaii on 6-8 Dec 2021. See also Section 1.3.1 for background on this phenomenon. The following is an excerpt from National Weather Service (NWS) report on the event:

> "A strong kona low developed northwest of the main Hawaiian Islands and produced heavy rainfall and strong winds over many areas of the state. The main rain band hit the Big Island first on Sunday, December 5, then shifted slowly westward across the island chain over the next two days. Rainfall totals were greatest over the southeastern flank of the Big Island, the south- and west-facing slopes of Haleakala, and most of Oahu,…"
> (https://www.weather.gov/hfo/konaLowDec2021)

At the request of the local sponsor for use in communication with local media, the H&H PDT examined gage records, published frequency information, and prior study information to assign an estimate of the return frequency for this event. It should be noted that this analysis exclusively focused on the Ala Wai watershed (Manoa, Palolo and Makiki subbasins) and may not be representative of other portions of Oahu or Hawaii. Based on both a precipitation frequency analysis and flow frequency analysis of gages within the basin, the storm event can be characterized as approximately a 20% AEP (commonly referred to as a “5-year”) event. Analysis of five precipitation gages and six discharge gages was performed in order to gain an overall understanding of the storm event and the watershed response, given that any individual result can be highly localized and not reflective of the overall event. Based upon the analysis of the precipitation gauges, the event 24-hour totals were generally consistent across the entire watershed, ranging from 7.79 inches to 8.89 inches. (See also Addendum D to this Appendix for more details on this event.)

Based upon available news reports and social media posts, with additional documentation by local PDT personnel, street flooding was the primary impact. Flooding also damaged the Iwilei Power Substation and an underground transmission cable, which is located just northwest of the watershed boundary, causing a power outage that affected much of the metropolitan area. Several water rescues also occurred, and other non-flooding damages (such as downed trees and mudslides) were observed. Precipitation and associated damages appear to be slightly greater in the Makiki watershed than the Palolo and Manoa watersheds. The general range in precipitation frequency is consistent with the runoff frequency estimates. When considering both sets of data, characterization of the storm overall as a 0.20 annual exceedance probability (“5-year”) event is a good estimate. The reports of primarily street flooding and minimal other damages also seems consistent with the estimated annual exceedance probability. See Addendum D for an expanded discussion of this event and the analysis conducted.

3. Hydraulic Model

As described in Section 1.2.2, the MMC updated a HEC-RAS model of the Ala Wai Watershed was updated to a 1D/2D unsteady model for the Validation Study using HEC-RAS version 5.0.7. That version of the hydraulic model went through DQC and an ATR. Due to the complex nature of the system and the model, it was determined that the General Reevaluation Study would use the base model from the Validation Study and only update the model to account for major changes due to new data available and to update the model to HEC-RAS version 6.2.

The Validation Study used USGS Lidar Data, Diffusion Wave equations in the 2D areas due to the mostly steep terrain and the gravitational forces, and channel data from the previous 1D hydraulic models.

The Validation Study model was updated utilizing HEC-RAS version 6.2, to incorporate new terrain data for more accurate flow conveyance and mapping (2019 Lidar of Ala Wai Canal), validated hydrologic parameters and methodology, verified and modified hydraulic structures based on site visits, validated the model with the DEC 2021 Kona Low, incorporated interannual variability into sea level rise assumptions for downstream boundary conditions, and analyzed coincident tidal and riverine flooding/sensitivity in the lower watershed.

3.1. Hydraulic Model Setup

The Ala Wai Watershed hydraulic model includes the Ala Wai Canal, the Makiki Stream, the Kanaha Stream, the Manoa Stream, the Palolo Stream, the Pukele Stream, and the Waiomao Stream. The unsteady flow model incorporates 1D channels with 2D overbank area. All significant structures were included in the model, including bridges, culverts, and inline structures. Some of the longer culverts were converted to lidded cross sections to allow more cross-sections over longer lengths which increased stability. Some of the natural channel drop structures are modeled as inline structures, but some were represented by cross sections to increase stability. It should be noted that the MMC modified the downstream extent of the model to extended into the ocean so that the downstream boundary condition does not unintentionally force potential errors in the canal. Figure 3-1 shows the HEC-RAS Geometry Schematic.

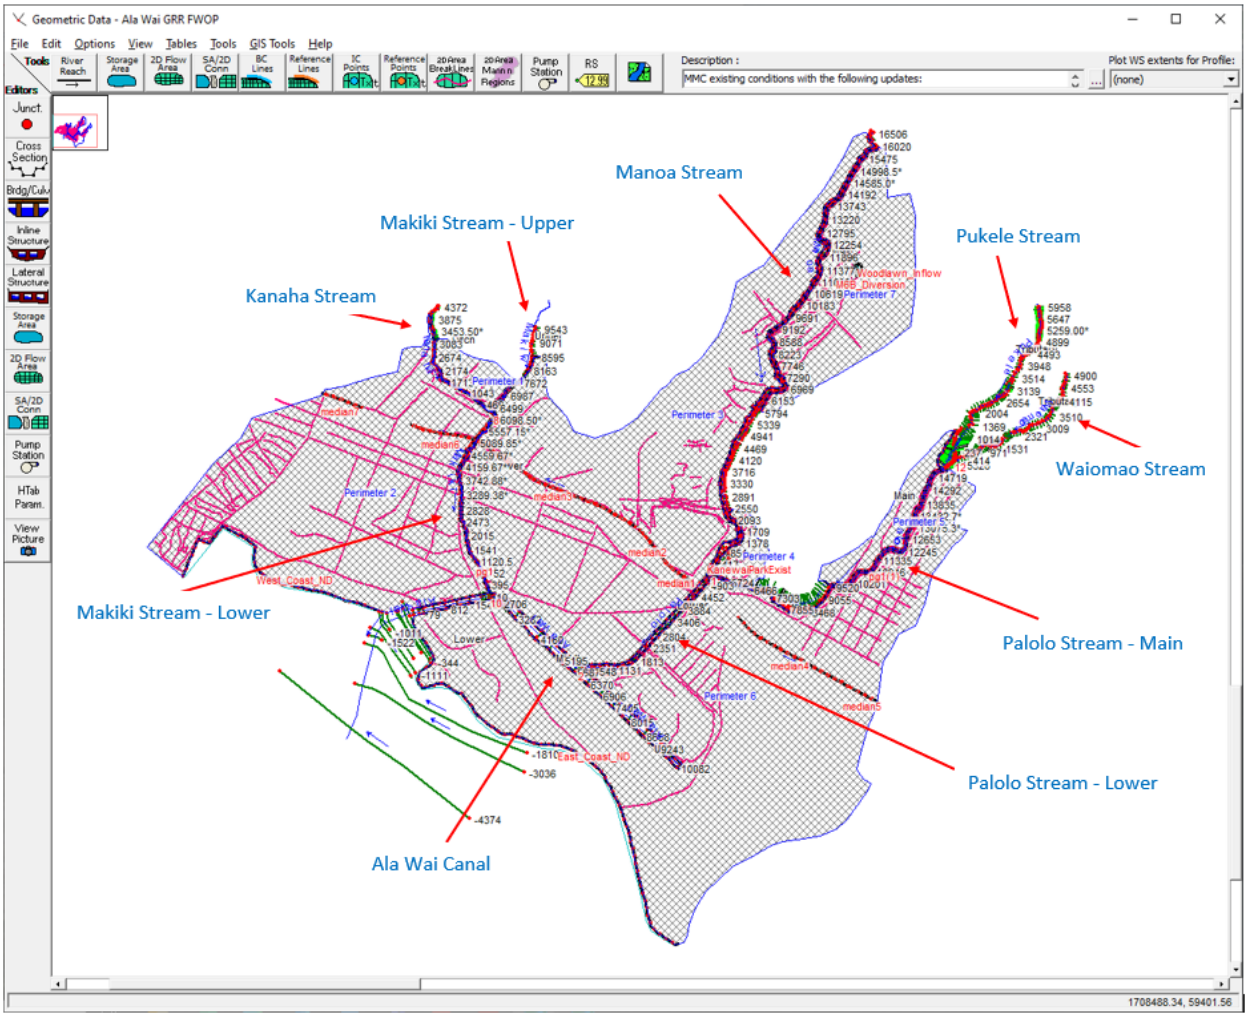

Figure 3-1: HEC-RAS Geometry Schematic

3.1.1. HEC-RAS Study Reaches

The Makiki Stream portion of the HEC-RAS model starts from the confluence with the Ala Wai Canal to a point approximately 2.0 miles upstream and includes the Kanaha Ditch Tributary from its confluence with Makiki Stream to a point approximately 0.8 miles upstream.

The Manoa Stream reach extends from the confluence with Manoa-Palolo Drainage Canal upstream about 3.1 miles to the point where the Waihi and Waiakeakua Stream tributaries meet. The Manoa Stream channel is mostly natural with some segments modified by concrete channel or stream bank hardening.

The Palolo Stream Main reach extends upstream approximately 1.9 miles from the confluence with the Manoa-Palolo Drainage Canal. Upstream of Palolo Stream, the Pukele Stream and Waiomao Stream tributaries were modeled, extending 1.1 and 0.9 miles upstream. The Palolo Stream Main reach channel is mostly confined to one large concrete channel with a few segments composed of natural channels.

The Manoa-Palolo Drainage Canal is called the Palolo Stream Lower reach in the model and extends about 0.9 miles from the Ala Wai Canal to the confluence of the Manoa and Palolo Stream. This canal consists of a modified channel with segments of natural bed and banks, but mostly hardened stream banks.

The Ala Wai Canal section is modeled using three reaches from the mouth of the to the Makiki Stream confluence (Lower), from Makiki Stream to the Manoa-Palolo Drainage Canal confluence (Middle), and from the Manoa-Palolo Drainage Canal confluence to the upstream end (Upper). The Ala Wai Canal channel has a natural bottom with hardened banks and has tidal influence.

3.1.2. MMC Model Base Terrain

Topographic data for the hydraulic model is primarily based on airborne light detection and ranging (LIDAR) data. The terrain used for this study was generated from 3 different data sources. The terrain data included SHOALS (Scanning Hydrographic Operational Airborne LiDAR Survey) data for the bathymetric coastal waters, LiDAR that was originally collected prior to February 21, 2007 by Airborne1, and bathymetric survey data for the Ala Wai Canal that was conducted by Oceanit on May 12, 2008. The airborne LiDAR data was collected, processed, and verified by Oceanit and their sub consultants in late 2006 and early 2007. The LiDAR data has an accuracy of 45 cm (1.5 ft) horizontal, 37 cm (1.2 ft) vertical and was processed with 1 ft horizontal point spacing. Datum of data is NAD 1983 HARN projected into Stateplane_Hawaii_3_FIPS_5103_Feet horizontal and mean sea level vertical.

The higher quality terrain was also modified to remove some bridge decks that were not properly removed so that water could move freely in these areas. In addition, the channel data from the existing HEC-RAS cross-sections was used to burn-in channel bathymetry in the terrain to provide improved mapping for the channels.

3.1.3. Ineffective Flow

The cross-sections are mostly contained to the channel extents for most areas, so ineffective areas were not necessary for most of the modeled cross-sections. However, any ineffective areas that were used in the previous model where the full cross-sections were retained (i.e. upper reaches of Kanaha, Makiki, Pukele, and Waiomao), the ineffective areas were preserved. In addition, some ineffective areas located around bridges and within the new reduced cross-section footprint, were also preserved.

3.1.4. Manning's "n" Roughness

The Manning’s n-values in the HEC-RAS hydraulic model were determined based on-site visits conducted by personnel from MMC, HEC, and POH for the different reaches for the Validation Study. The site visits were conducted 6-8 November 2018. Due to the lack of calibration data throughout the watershed, the roughness was estimated based on a consensus of several senior hydraulic engineers that participated in the site visits to ensure reasonable values were used for the channels. Since the 1D cross-sections were only used to model the channel portion, a composite ‘n’ value was used for the entire channel portion which would include the sides of the channels.

The range of Manning’s n-values used can be roughly characterized by channel description. Natural stream channels with minimal vegetation in the channel, steep banks, trees and brush

on banks, and bottoms consisting of gravels, cobbles, and few large boulders were given values from 0.04 to 0.08. Natural channel sections that were uniform and contained smooth graveled beds were given a value of 0.028. The Ala Wai Canal was given an n-value of 0.03. Lined or concrete channels were given a value of 0.022 to 0.025. For concrete lined channels on the Palolo, the roughness was estimated to be approximately 0.022 due to the aged concrete, exposed aggregate, and steepness. For Makiki, concrete lined channels were given a value of 0.025 due to the sedimentation, plant growth along the wall, and the rougher side walls that were made with lava stone. The majority of overbank areas in mixed urban areas or overland flow areas were given values of 0.07 to 0.125. The overbank values varied based on the land use type in the overbank. For example, overbank cross-sections that intersected open park areas had a lower value compared to those that more vegetation or higher density of buildings.

The roughness of the 2D areas were based on the 2011 Coastal Change Analysis Program (C-CAP) Land Cover for Oahu. The land cover data was supplemented with building footprints from a 2009 dataset from the National Geospatial-Intelligence Agency (NGA). Manning’s roughness for some land cover fields were estimated using values from Zhang, K & Yuepeng, L. 2017 “Transition of the Coastal and Estuarine Strom Tide Model to an Operational Model for Forecasting Storm Surges” Florida International University. Figure 3-2 shows the values used for the 2D land cover data. More information on the Manning's "n" values in the model can be read in the Validation Study Hydraulic Engineering Report.

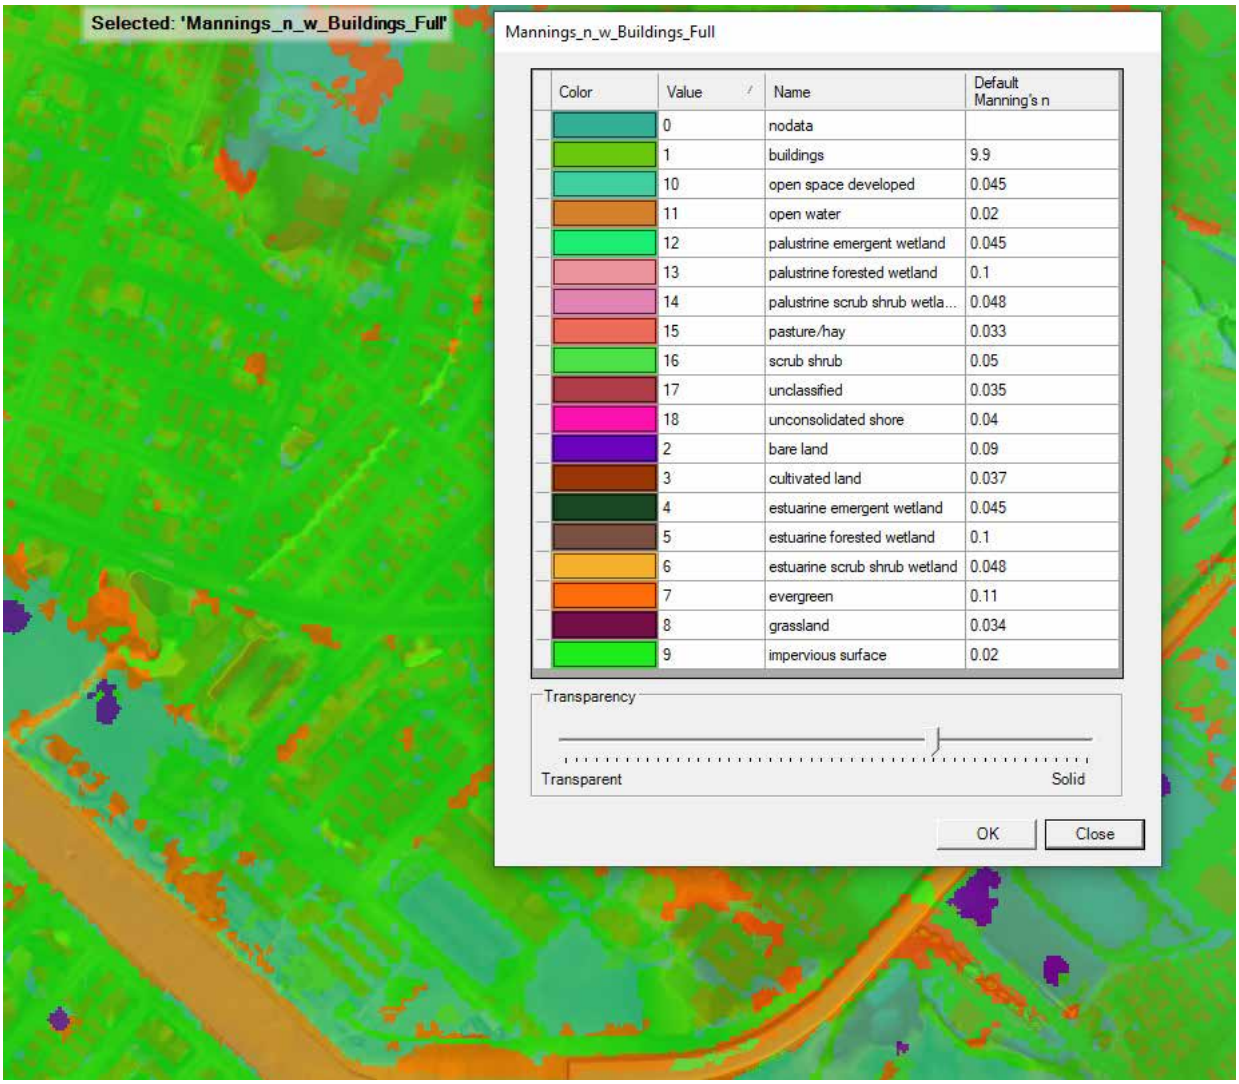

Figure 3-2: Manning's "n" Layer in RAS Mapper

3.1.5. Lateral Structures

The base MMC hydraulic model has lateral structures that utilize both 2D equations and weir equations, with weir coefficients set for both. During the alternative modeling, it was discovered that when using culverts in lateral structures, HEC-RAS switches to always use the weir equation, even if 2D equations are selected. HEC says this is intentional and not a bug as adding culverts imposes another boundary condition on the lateral structure that is not compatible with the 2D equations. The software fix will likely be to grey out the 2D equation button when culverts are added, but that won't take effect until HEC-RAS v 6.4 or later. HEC recommends using the weir equation for lateral structures when flow goes through critical depth (such as flow overtopping a floodwall).

As the existing base MMC model uses lateral structures to represent ground elevations to connect cross section overbank ground elevations to the 2D area ground elevations, the issue of flow going through critical depth and the need for lateral structure weir equations is not seen as a critical concern by the H&H modeling team as the flow is generally not going through a drop and critical depth. After some investigation and trial runs, it was determined by the H&H modeling team that the existing FWOP geometry would not be changed, and the lateral structures would be modeled using both the 2D equations (when representing ground elevations) and weir equations.

For the With Project alternatives modeling, all lateral structures that are being used as floodwalls, whether or not there are culverts, will use the weir equations with a weir coefficient of 2.0 to represent the structure and that the flow is going through critical depth when it flows over the top. All of the lateral structures that are not modified as part of a floodwall measure, but represent the ground elevation, will be kept the same as the FWOP with 2D equations. As the floodwall measures are creating a different hydraulic condition, the difference of weir equations for the lateral structures as floodwalls is justified.

3.1.6. Boundary Conditions

As Section 2.1 describes, a review of the Validation Study Hydrologic Analysis was conducted, and it was determined that the hydrograph inputs from the Validation Study were still appropriate for this GRR Study. The DSS file of the finalized HEC-WAT balanced hydrographs from the Validation Study was used for the GRR Study.

As the hydrologic analysis did not need to be updated, all of the model inflow hydrographs stayed the same as the Validation Study except for the downstream boundary conditions for the Ala Wai Canal. That downstream boundary conditions analysis is described below in Section 3.5 Downstream Boundary Conditions. A full write up of the HEC-RAS unsteady flow boundary conditions used in the MMC model can be found in the Validation Study Hydraulic Modeling Report located in Addendum C, but a table of the hydrologic inflows into the hydraulic model can be seen below in Table 3-1. These inputs match the Validation Study boundary conditions for without project conditions. The GRR study uses these inflows for both the future without project conditions and for the with project conditions.

Table 3-1: HEC-RAS Boundary Conditions - Unsteady Flow Hydrologic Inputs

HEC-RAS				HEC-HMS	
River	Reach	River Station(s)	Type	Element Name	Type
Ala Wai	Upper	10082	Flow Hydrograph	JA1	FLOW
Kanaha	Ditch	4372	Flow Hydrograph	K2A	FLOW

2D	Perimeter 7	M6B_Diversion		WOODLAWN SEWERSYSTEM	FLOW-DIVERSION
2D	Perimeter 2	West_Coast_ND		s = 0.001	
2D	Perimeter 6	East_Coast_ND		s = 0.001	

3.2. Updates to MMC Model

This GRR study utilized the Validation MMC model as a base, with updates made based on updated capabilities of the modeling software, updated terrain and survey data, observed data and measurements, and updates to evaluated future conditions sea level rise and interannual variability.

The HEC-RAS hydraulic model was updated to run in HEC-RAS version 6.2, as there were some significate changes to the modeling software between HEC-RAS version 5.0.7 and 6.2.

New terrain data was incorporated into the modeling terrain for more accurate flow conveyance and mapping using new Lidar of the Ala Wai Canal and the immediate overbank from 2020 and post dredge Bathymetric survey data from 2021.

Observations and field measurements were taken while on a project site visit, and some changes were made to the model, especially a change to the Manoa Palolo Canal to add in the H1 West Bound off ramp pier located just downstream of the H1 interstate and upstream of King Street.

The hydraulic model was verified to the December 2021 Kona Low flooding to increase confidence of within-bank flows.

The hydrologic inflows used in the Validation Study were directly used in the GRR study. Due to the changes listed above, the minimum flows that were used in the Validation Study for model stability had to be increased for the GRR study. While these minimum flows are required for the numerical modeling, they do add some uncertainty to the modeled results, especially for the lower, more frequent flood flows. While all of the minimum flows were less than the 50% AEP event peak flood flows, this does overestimate the volume of flood water for the smaller, more frequent flood events. This becomes minimal impact for the larger flood events.

And finally, the future conditions sea level rise to include interannual variability was evaluated, a correlation analysis between the NOAA coastal gage and the USGS riverine gages was conducted, and a sensitivity analysis of tidal events on the lower watershed was conducted in order to determine the most appropriate downstream boundary conditions.

3.2.1. New Survey/Terrain Data

As part of the 2020 Ala Wai Canal Flood Risk Management Project's Topographic Survey/Mapping, Geotechnical, and Sediment Sampling Data Collection effort completed by contract from Sam O. Hirota, Inc (Hirota 2020), an updated lidar DEM terrain of the Ala Wai Canal was created. The project extents from this data collection effort is shown in Figure 3-3. That updated lidar data was used to update the Ala Wai Watershed terrain.

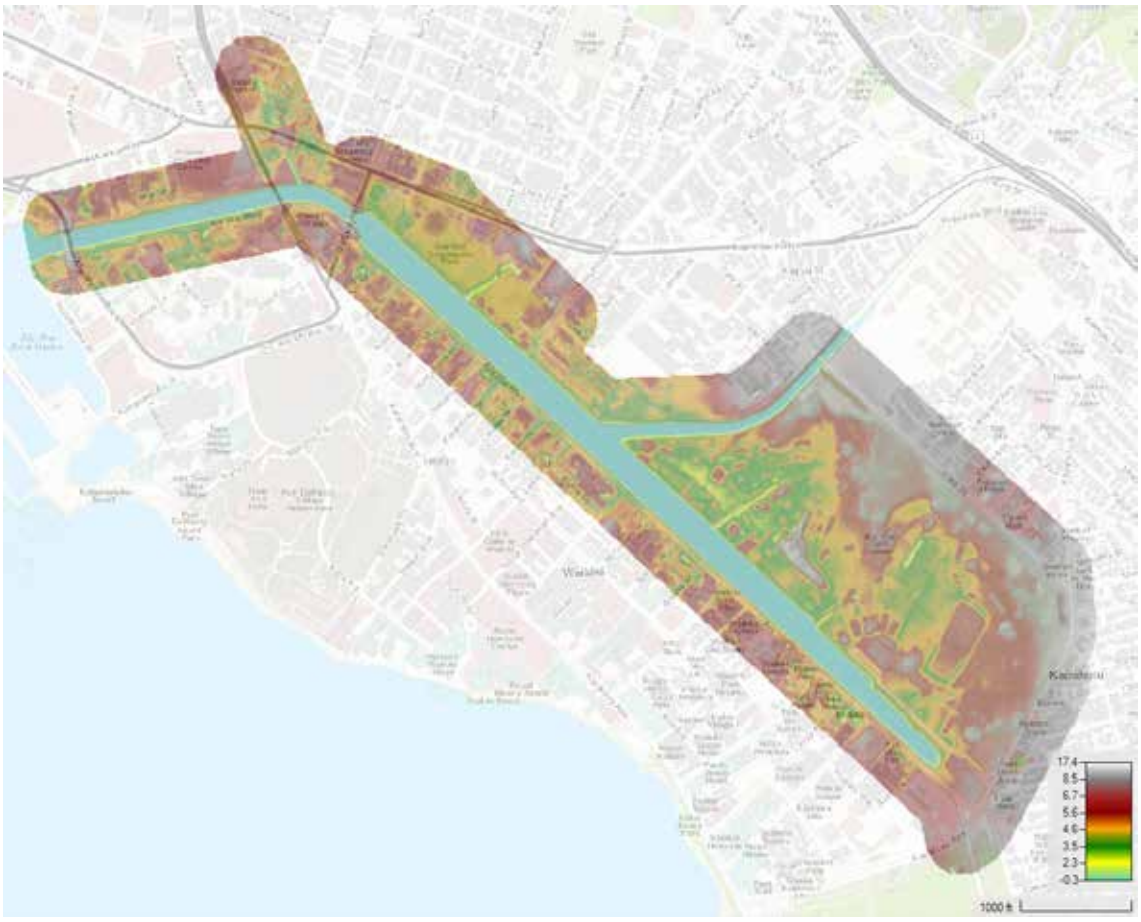

Figure 3-3: Hirota's 2020 Topographic Survey/Mapping Project Extent

The State of Hawaii Department of Land and Natural Resources dredged the Ala Wai Canal in 2021. As part of that effort, a post dredging topographic survey of the Canal was conducted (DLNR 2021). See Figure 3-4 for the extents of the bathymetric survey. That updated bathymetric data was used to update the Ala Wai Watershed terrain.

Figure 3-4: DLNR Post-Dredge Survey Extents (black area)

To incorporate these two new data sets into the HEC-RAS terrain data, the two new terrain layers, the Hirota 2020 Lidar terrain and the post dredge survey terrain, along with the existing terrain layers, the channel terrain and the base LiDAR terrain. The post dredge survey terrain was set as the top priority, followed by existing channel terrain dataset, followed by the Hirota Lidar, and then finally the base LiDAR terrain. HEC-RAS created a tiled terrain dataset using all the provided terrain datasets. You can see the MMC terrain data in Figure 3-5 and the updated terrain in Figure 3-6.

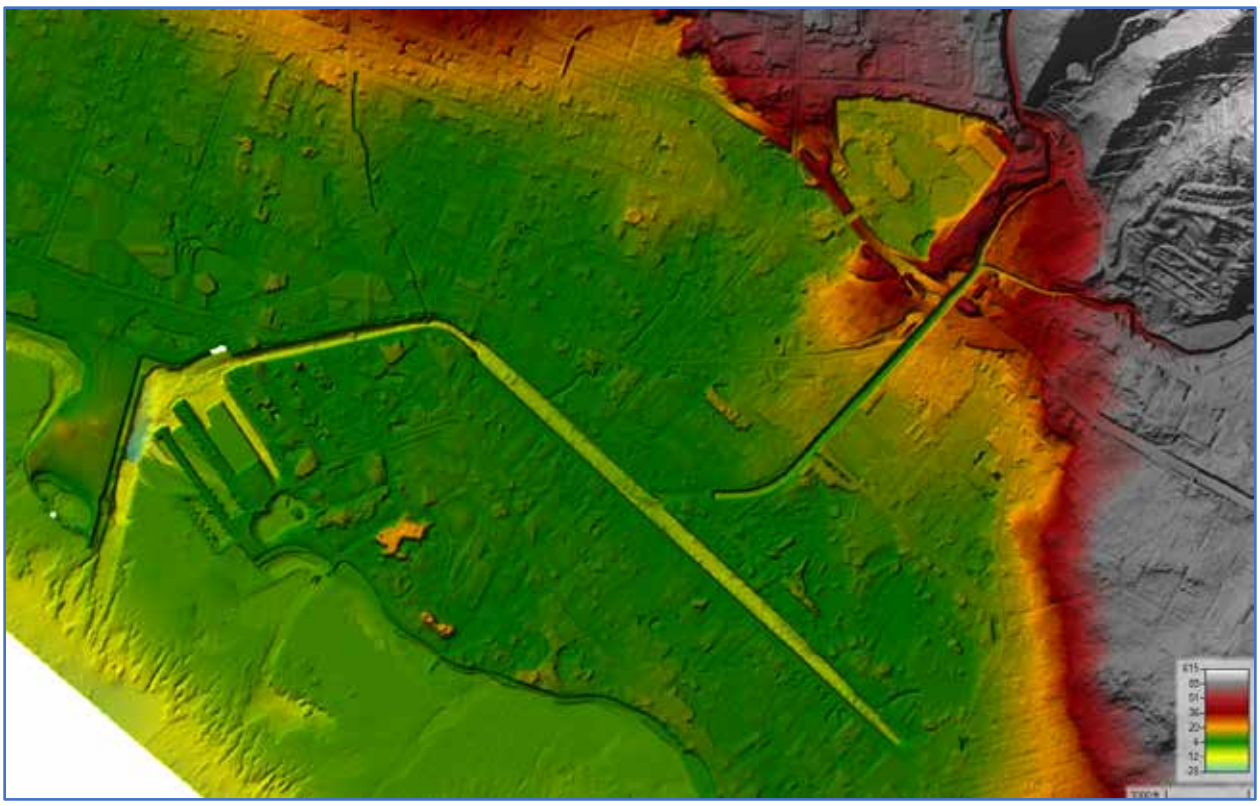

Figure 3-5: Terrain Data used in the MMC HEC-RAS Model

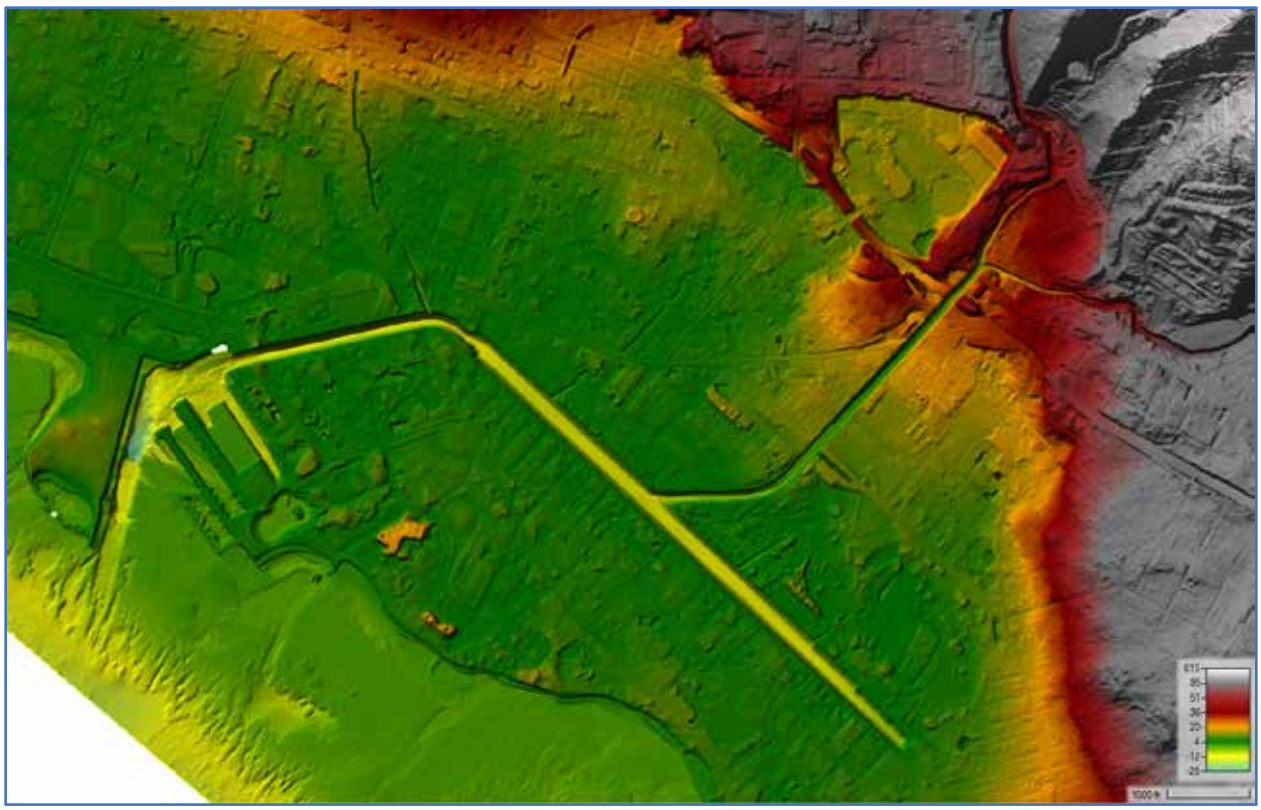

Figure 3-6: Terrain Data used in the Updated HEC-RAS Model

The only changes to the terrain data is near the Ala Wai Canal, but those changes due to the new data available after the Validation Study made some big changes in the Ala Wai cross sections and in the lower 450 feet of the Makiki Stream. An example of that change for the Ala Wai Canal in shown in Figure 3-7, and an example of the change in terrain for the lower Makiki Stream is shown in Figure 3-8.

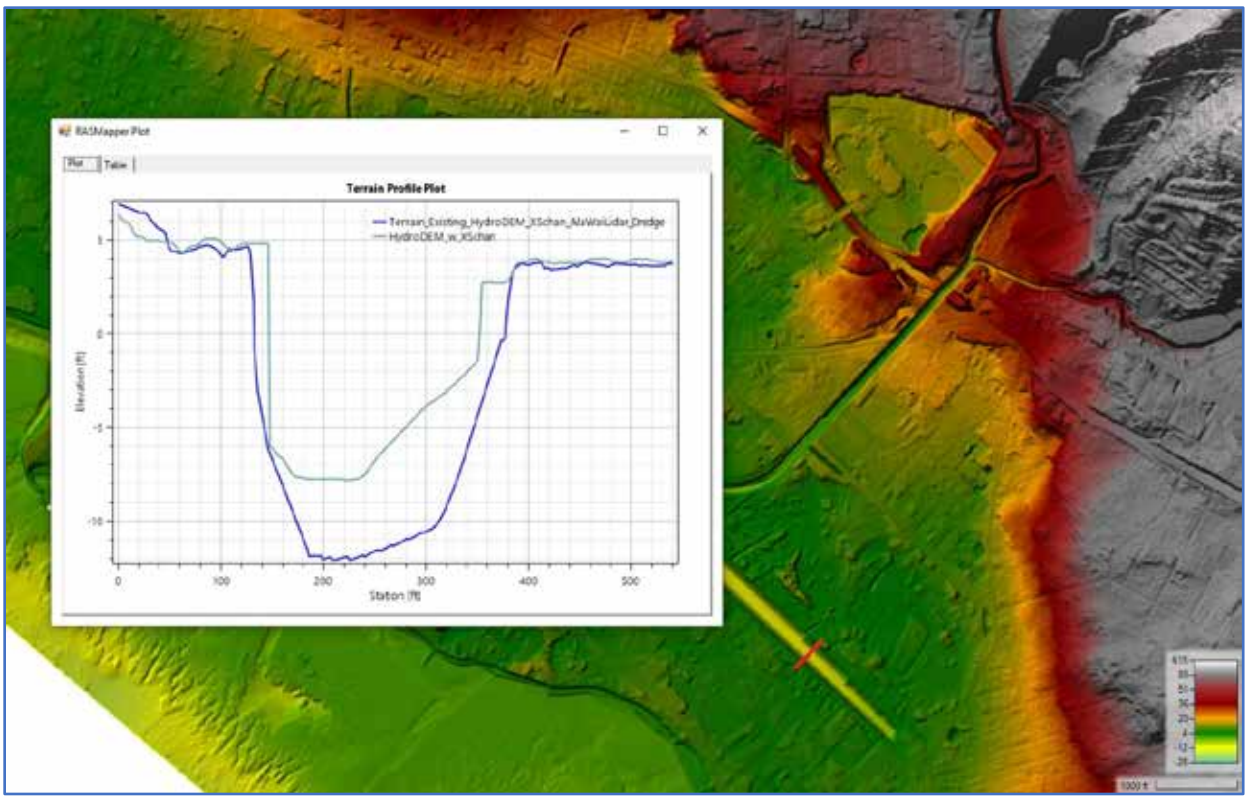

Figure 3-7: Example of Terrain Difference on the Ala Wai Canal, the cyan line is from the Validation Study terrain and the dark blue line from the modified terrain.

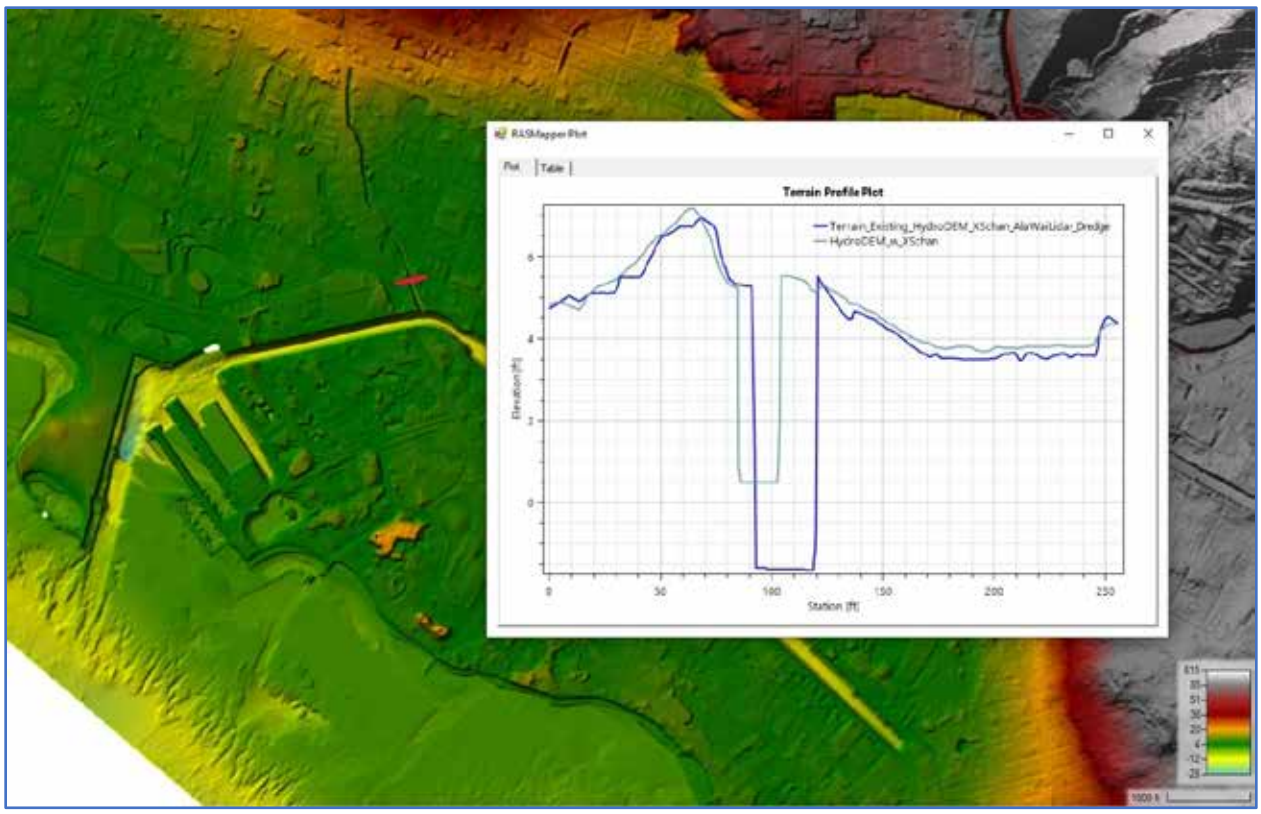

Figure 3-8: Example of Terrain Difference on the Makiki Stream near the Confluence with Ala Wai Canal, the cyan line is from the Validation Study terrain and the dark blue line from the modified terrain.

The updated Lidar data along the Ala Wai Canal and the updated post dredge survey bathymetric data was used to modify the canal, as they were the best available data provided and they collaborated the fact that the modeled canal width of the Ala Wai Canal was off by over 30 feet in the upper sections and the model was off near McCully Bridge; the decision to use the post dredge bathymetric data was coordinated with the PDT with no objections. There is some risk associated with using the surveyed post dredge bathymetric data, however. There is a gradual reduction of depth and associated conveyance area in the canal as time goes on due to sediment buildup before the next dredging occurs. A sensitivity of the post dredge survey channel vs the MMC model channel representing a large sediment buildup was conducted to see the possible range of water surface elevations that can occur during the canal sediment cycle of filling up, and then dredging again. For the modeled future without project 10% AEP flood with full sedimentation in the canal, there is up to a 0.5 foot increase to the Upper Ala Wai Canal water surface elevations, and for the modeled future without project 1% AEP flood with full sedimentation in the canal, there is up to 1.5 foot of increase due to sediment. It is assumed that the canal will continue to be dredged, as needed, for sediment maintenance. Sedimentation of the Ala Wai Canal will be a risk factor during the Risk Assessment and during PED phase.

3.2.1.1. Model Updates due to Updated Terrain/Survey

After the Ala Wai Watershed existing conditions terrain data was updated with the two new data sources, the HEC-RAS hydraulic model was updated to more accurately represent flow conveyance and overland flooding near the Ala Wai Canal. A list of the changed made are shown below:

Ala Wai Canal channel geometry updated from the 2020 Hirota Lidar and the 2021 DNLR post dredge survey. This changed the modeled channel width from 220 ft to actual 250 ft in some reaches. The following bridges were also updated:

- Modified Ala Mona Blvd Bridge based on the 2020 Hirota survey.
- Modified Kalakaua Ave Bridge based on the 2020 Hirota survey.
- Modified McCully Ave Bridge based on the 2020 Hirota survey.

Manoa Palolo Canal near the Ala Wai Canal confluence updated from the 2020 Hirota Lidar and the 2021 DNLR post dredge survey.

Makiki Canal near the Ala Wai Canal confluence updated from the 2020 Hirota Lidar. This changed the modeled channel width from 20 ft to 28-32 ft in the lower 450 feet of the reach.

Makiki Canal Ala Wai Prominade bridge added from the 2020 Hirota Lidar and survey. Bridge added as cross section with lids for model stability.

Multiple breaklines added to refine the 2D mesh.

3.2.1.2. Terrain Updates for Alternatives

The terrain for some measures were modified to include some of the proposed structures such as the Makiki District Park Detention Basin and the Manoa Detention Basin. During the screening of measures, other detention basins were also added into those terrain files. The Makiki and Manoa Detention Basins were included in the three alternatives modeled. The detention basin terrain was produced by the detention basin designers from the PDT. They provided the updated terrain from their CAD software. To incorporate this into the HECRAS terrain data, the detention basin terrain was selected as additional terrain data along with the channel terrain data, the Ala Wai post dredge channel terrain data, the Hirota 2020 Lidar data, and the base LiDAR terrain. The detention basins were set as top priority, followed by the two channel terrain datasets, the Hirota Lidar, and then finally the LiDAR terrain. HEC-RAS created a tiled terrain dataset using all the provided terrain datasets.

3.2.2. Site Visit

The technical team conducted a site visit 21–24 March 2022 for the Ala Wai Canal General Reevaluation Study. The project managers (Eric Merriam, LRP and Cindy Acpal, POH), hydraulic engineer (Shelley Tule, LRE), structural engineer (Kathy Sitko, LRC), geotechnical engineer (Samantha Schardein, LRL), and civil engineer (George Uku, LRN) visited critical areas within the Ala Wai watershed to provide the technical engineering team an opportunity to

see the study area, collect additional data required for upcoming technical analyses, and visit potential measure locations.

The team assessed the channels and bridges in the Makiki subbasin, taking numerous photos and measurements. Along the Kanaha Stream, the team specifically took measurements of the Kewalo Street bridge where the model shows a low point. The model was verified with the field measurements. Along the lower Makiki Stream, the team also noted that community members placed additional concrete blocks on the floodwall, extending its height in the area upstream of Fern Street. Several measurements were taken at the Fern Street bridge. After much discussion, it was determined that those additional concrete blocks would not be included in the model as they were not engineered, and no survey of elevations or extents were available.

The team also assessed many bridges along the Manoa-Palolo Canal. The hydraulic engineer noticed that large rocks had been deliberately piled under the Kapiolani Blvd. bridge, which could have potentially affected the hydraulic model. As the large rocks were taken from the same general cross section of the river, though, no loss of conveyance was estimated, and the model was not changed. The hydraulic engineer also noted a large bridge pier for the H-1 westbound off ramp (located upstream of the King Street bridge) that was not in the existing model. Measurements were taken in the field, and the pier was added to the hydraulic model.

3.2.3. 2D Equations: Diffusion Wave vs Full Momentum

The Validation Study used Diffusion Wave equations in the 2D areas due to the mostly steep terrain and the gravitational forces and for model stability. This General Reevaluation Study investigated the need to update the 2D area to the Full Momentum Equations, especially as the updated version of HEC-RAS now allows for not just the Full Momentum (original) equations, but the more stable Full Momentum (stricter) equations.

As it applies to this model in general, per the HEC-RAS 2D User's Manual, there are potentially a few situations where the Full Momentum equation may offer more accuracy over the Diffusion Wave equation:

1. Highly Dynamic Flood Waves – Local acceleration and convective acceleration terms lacking in the Diffusion Wave equations are important to model rapidly rising flood waves accurately. Given the terrain of the region this is exactly what we see (i.e., rapidly rising flood waves) thus the Full Momentum equation may give a better representation of overland flooding.
2. General Wave Propagation Modeling – The Full Momentum equation will provide more accuracy on wave propagation due wave run-up on floodwalls, berms, etc. within the 2D areas.
3. Detailed Velocities and Water Surface Elevations at Structures – The Full Momentum equation will provide better detail around buildings.

The other situations listed in the HEC-RAS 2D User's Manual where the Full Momentum equations are preferred do not appear to be as applicable to this model:

4. Abrupt Contractions and Expansions – As this is a combined 1D/2D model, most inline structures are modeled in 1D.
5. Flat Sloping River Systems – The terrain has a high degree of slope in the upper to middle areas and flattens as you approach the coast. However even the flatter areas of the model appear to exceed the definition of very flat (less than 1 ft/mi slope).
6. Tidally Influenced Conditions – The d/s boundary on the Ala Wai canal is held at a constant elevation for this model.
7. Super Elevation around Bends – As this is a combined 1D/2D model all the river channels are modeled in 1D.
8. Mixed Flow Regime – As this is a combined 1D/2D model all the river channels are modeled in 1D.

The Full Momentum equation can provide more accurate velocities around buildings and more accurate arrival times of flood waves, so there was a need to investigate those equations. We need confidence in is where is it flooding, and once we have confidence in that then measures can be added to the model to restrict water to the channel to lessen overland flooding. Given

this, a comparison of the area inundated, and depth of inundation should be sufficient in determining whether the Full Momentum equations offers a more accurate solution.

For comparison, a 1% AEP FWOP simulation was completed using the Diffusion Wave equation, Full Momentum Equation (original) equation, and Full Momentum (stricter) equation with everything else held constant.

Table 3-2 below provides a summary of resulting volume errors by 2D Area when run with both Diffusion Wave and both sets of Full Momentum equations with all else held constant, such as time step and 2D slicing. It should be noted that minor changes were made to the FWOP model runs since these test runs but the sensitivity analysis is still applicable.

Table 3-2: Diffusion Wave vs Full Momentum Volume Errors by 2D Area

Volume Accounting for 2D Flow Areas in Acre Feet					
	Diffusion Wave	Full Momentum (original)		Full Momentum (stricter)	
2D Area	Percent Error	Percent Error	Increase (Decrease)	Percent Error	Increase (Decrease)
Perimeter 1	0.146	0.1925	0.04650	0.1005	(0.04550)
Perimeter 2	0.2754	0.5155	0.24010	0.05244	(0.22296)
Perimeter 3	28.71	0.2123	(28.49770)	0.04279	(28.66721)
Perimeter 4	2.567	1.282	(1.28500)	1.299	(1.26800)
Perimeter 5	0.002444	0.003592	0.00115	0.002539	0.00010
Perimeter 6	18.31	5.408	(12.90200)	0.002767	(18.30723)
Perimeter 7	0.03866	0.000892	(0.03777)	0.000379	(0.03828)

The Full Momentum (stricter) equation does show a decrease in volume error (with one exception) compared to the Diffusion Wave equation.

The graphs below show the difference between the Diffusion Wave and SWE-ELM Full Momentum (original) equations and the Diffusion Wave and SWE-EM Full Momentum (stricter) equations, for maximum computed flow and WSEL along the Palolo. As can be seen, the Full Momentum simulations are generally within 1 ft of the Diffusion Wave for most of the reach. This is seen in the additional reaches as well. The exceptions (above 1 ft) are occurring primarily near junctions and inline structures. These differences could be a result of overland flow transfer back into the 1D reaches from the 2D areas, where the Full Momentum equations provide more accuracy in this transfer than the Diffusion Wave.

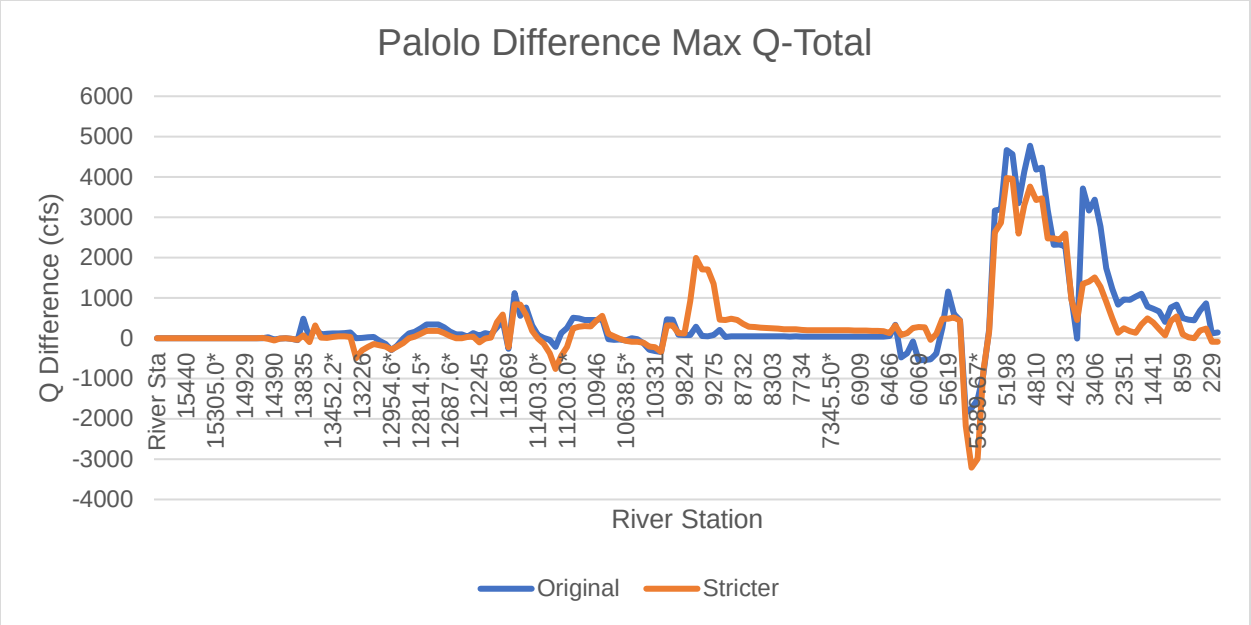

Figure 3-9: Difference of Max Discharge from Diffusion Wave vs Full Momentum SWE-EM (Stricter in orange) and SWE-ELM (Original in blue) on Palolo

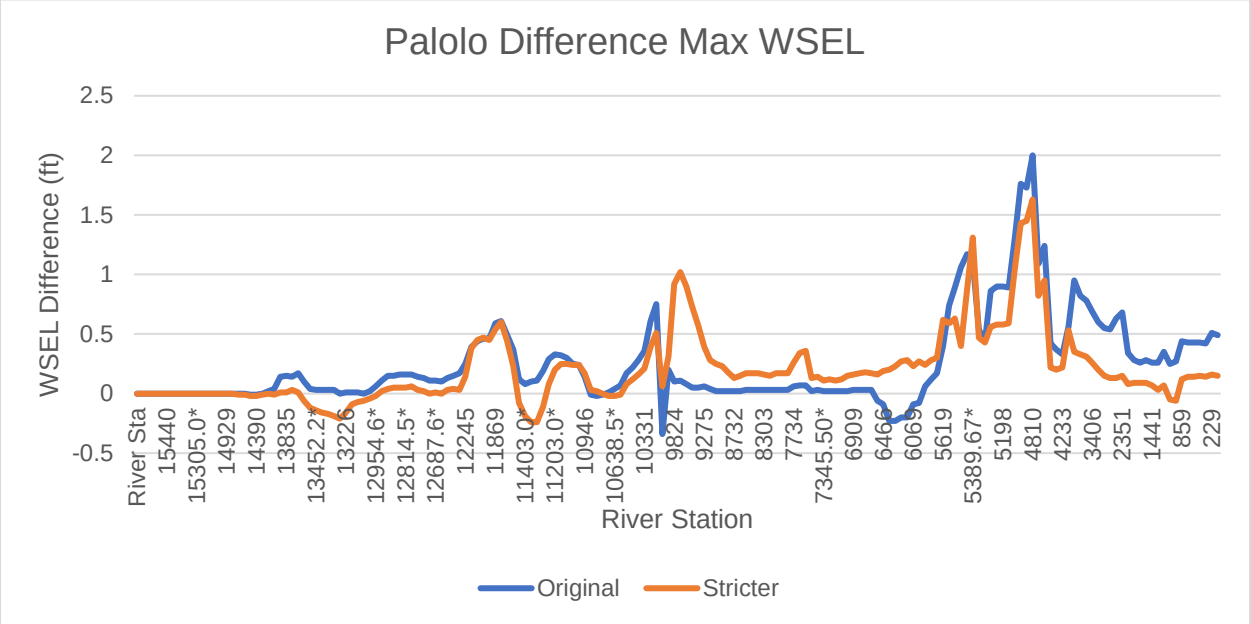

Figure 3-10: Difference of Max WSEL from Diffusion Wave vs Full Momentum SWE-EM (Stricter in orange) and SWE-ELM (Original in blue) on Palolo

Looking at inundation area of both the Diffusion Wave and SWE-ELM Full Momentum (original) equations in Figure 3-11 and the Diffusion Wave and SWE-EM Full Momentum (stricter)

equations in Figure 3-12, there are similar results, but you do see a slight increase in inundation in a few locations for both the SWE-ELM Full Momentum (original) equations (shown in pink) and the SWE-EM Full Momentum (stricter) equations (shown in green) approaches.

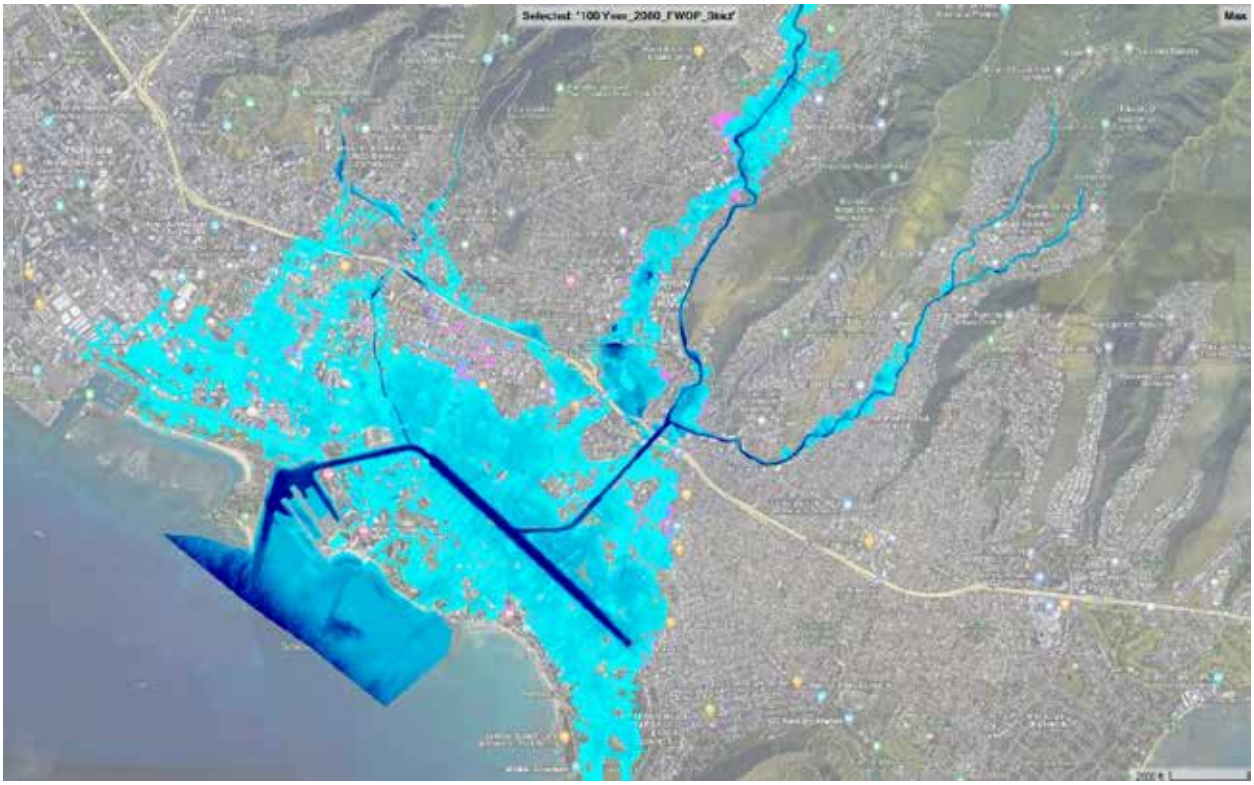

Figure 3-11: Inundation with Diffusion Wave (the blue areas) vs SWE-ELM Full Momentum (original) Equations (additional areas in pink).

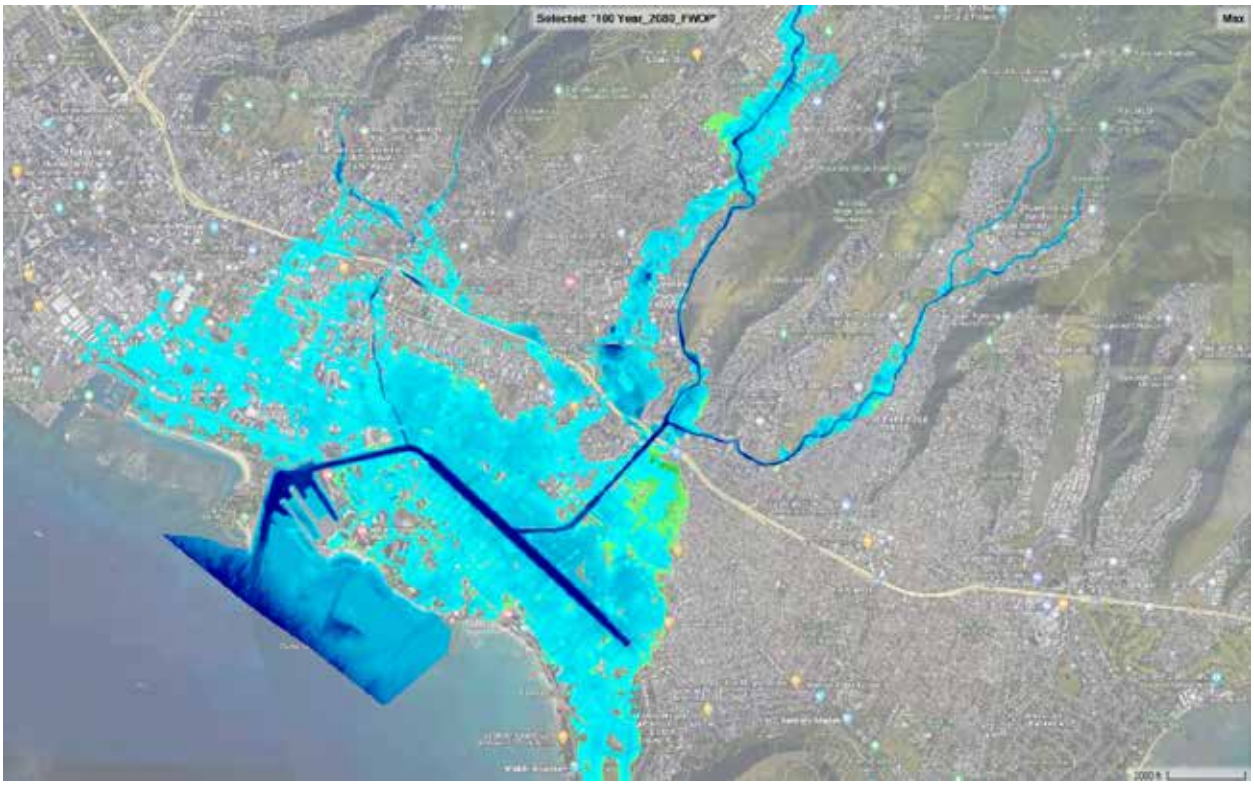

Figure 3-12: Inundation with Diffusion Wave (the blue areas) vs SWE-EM Full Momentum (stricter) Equations (additional areas in green).

Looking at inundation depth, the Full Momentum equations are generally within +/- 1 ft of the Diffusion Wave for both the SWE-ELM Full Momentum (original) equations, shown in Figure 3-13, and the SWE-EM Full Momentum (stricter) equations, shown in Figure 3-14, with orange/green areas <= 1 ft difference.

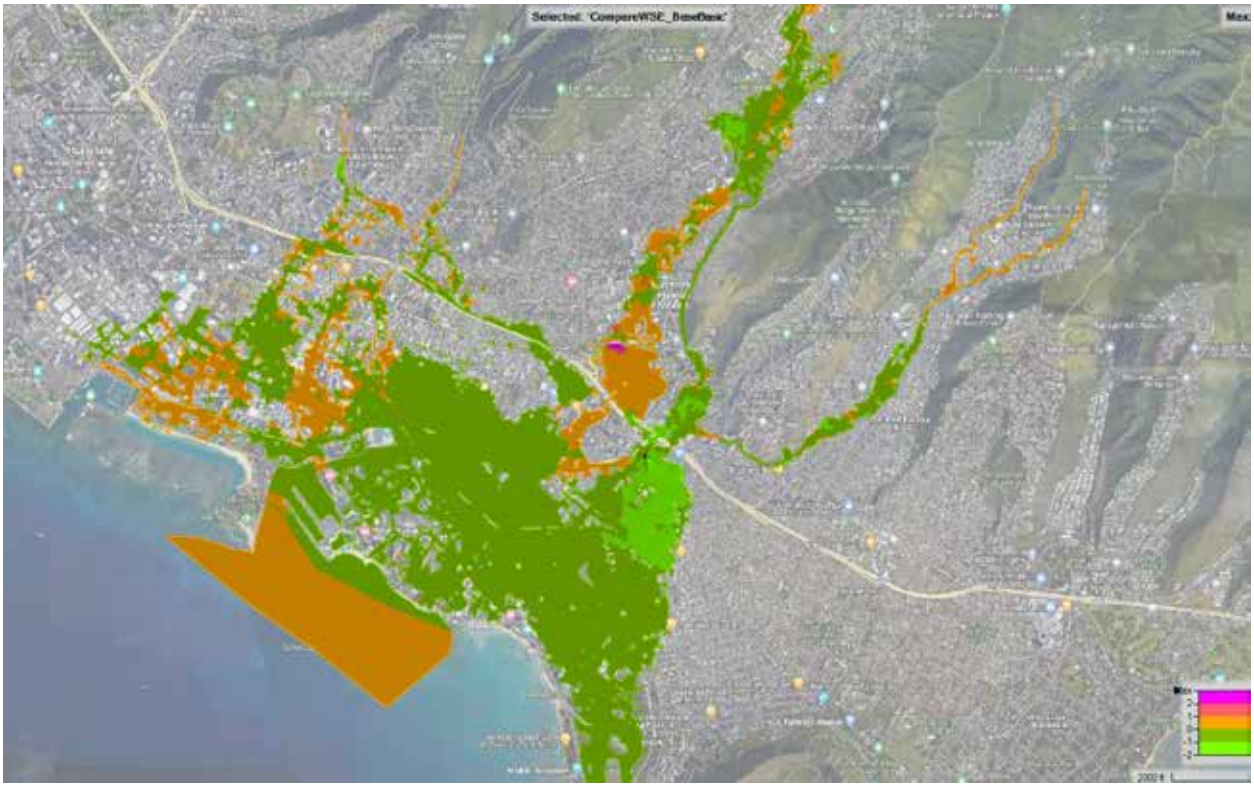

Figure 3-13: Change in inundation depths for Diffusion Wave vs SWE-ELM Full Momentum (original). The orange/green areas show <= 1 ft difference in depths.

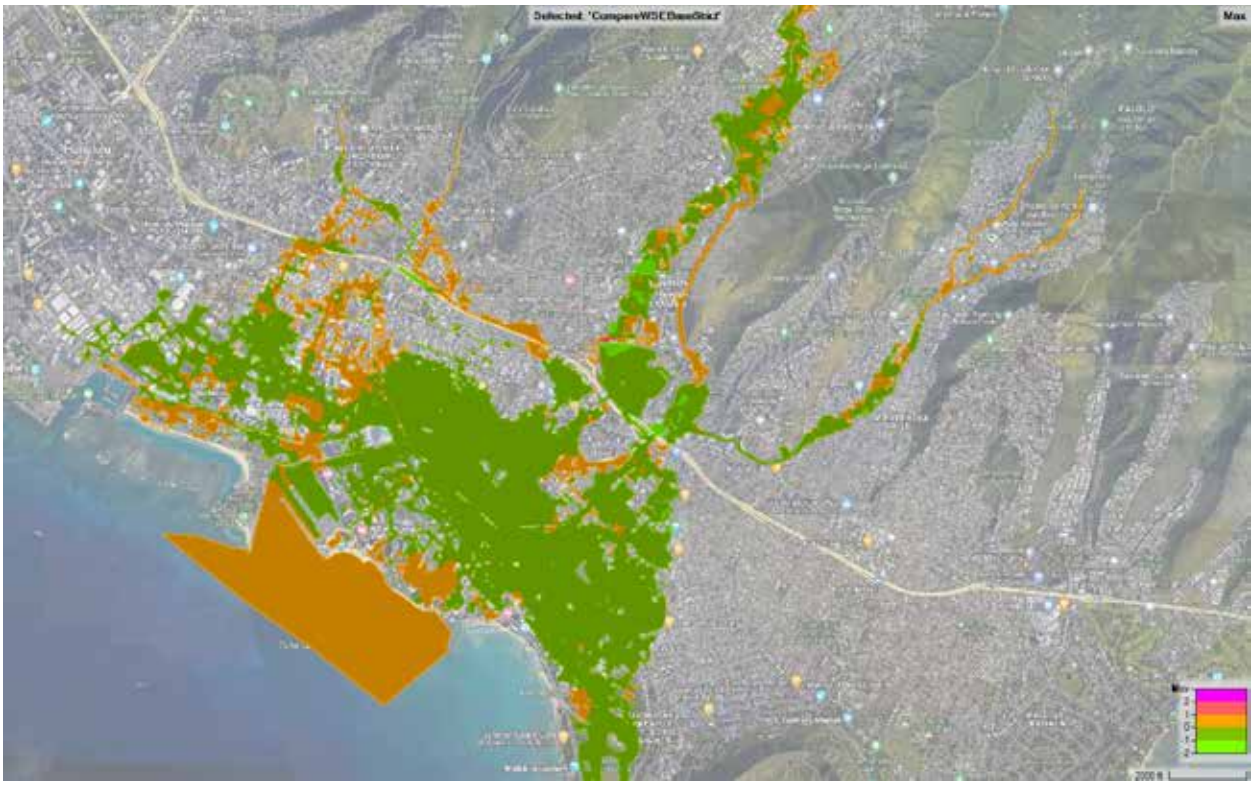

Figure 3-14: Change in inundation depths for Diffusion Wave vs SWE-EM Full Momentum (stricter). The orange/green areas show <= 1 ft difference in depths.

An area of excessively high differences was noted between the Diffusion Wave and SWE-ELM Full Momentum (original) equations in the Kaimuki High School region. This appears to be a result of some instability in the SWE-ELM Full Momentum (original) model for this 2D area. Figure 3-15 below compares the hydrograph for a cell within this region, clearly showing the instability in the SWE-ELM Full Momentum (original) equations, but stability for the SWE-EM Full Momentum (stricter) equations.

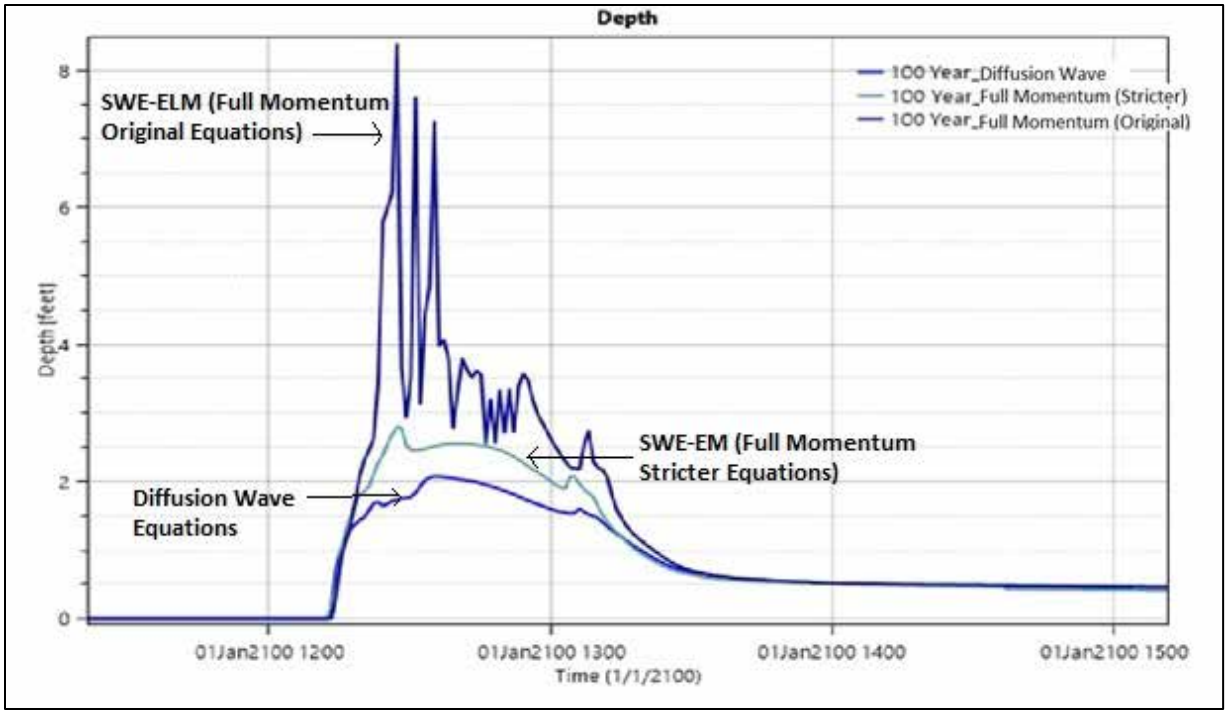

Figure 3-15: Hydrograph from a 2D cell in the Kaimuki High School Region with large WSEL Differences in the Diffusion Wave and SWE-ELM Full Momentum (original) Equations vs SWE-EM Full Momentum (stricter) Equations

The water surface elevations in the 1D channels were also quickly looked at. The SWE-ELM Full Momentum (original) equations results in much higher WSELs than the Diffusion Wave in some areas, and there were more errors in the higher flood events. The SWE-EM Full Momentum (stricter) equations produced similar WSELs as the Diffusive Wave equations. `

Based on these general observations, there was a need to use the SWE-EM Full Momentum (stricter) equations for the purpose of this study. The instability and increased volume errors shown in the 2D areas using the SWE-ELM Full Momentum (original) equation, which were the only Full Momentum equations available in the older versions of HEC-RAS, explains why the Validation Study used the Diffusion Wave Equations. The Full Momentum (stricter) equation available now appear to provide a more accurate and stable solution in the 2D areas, and while not significantly more so than the Diffusion Wave, enough that the model was converted. This, however, did increase the model run times significantly.

3.3. Model Update Comparison

The Validation Study made huge changes to the hydraulic model by converting from the Feasibility Study 1D model to a 1D/2D model, so the report documented the change in water surface elevations for the 1% AEP flood event in a few select locations. With the changes made to the hydraulic model for this GRR study, a quick comparison of the results to the Validation Study was made at the same location and using the same table as reference, but with adding the GRR model results. See Table 3-3 below.

Table 3-3: WSEL for the 1% AEP at Select Locations between the Feasibility, the Validation, and the GRR Studies

HEC-RAS Reach	Cross-Section ID	Cross-Section ID		1% AEP Event (100 year) - Without-Project				
Name	Original Modeling	New 1D/2D Model	Location Description	2017 Feasibility WSEL (ft)	2020 Validation 1D/2D Model WSEL (ft)	Difference Validation to Feasibility (ft)	2023 GRR 1D/2D Model WSEL (ft)	Difference GRR to Validation (ft)

3.4. Calibration/Validation

3.4.1. Existing MMC Calibration

There have been only 3 significant flood events in the observed record, and these events (the 1967, 2004, and 2006 storms) were used as best as possible for calibration during the Validation Study. Observed flows were not available in the detail needed to calibrate an unsteady model, so the HEC-HMS model was used to route the rainfall from those events and provide inflows into the model. It should be noted that only the Manoa-Palolo portion of the basin was available for the 2006 event. See the Validation Study Hydrologic Report for this study to find more details on the HEC-HMS calibration for these 3 events.

Previous modeling on Manoa Stream (Oceanit, 2008b) was calibrated to the 2004 flood event on Manoa Stream. Previous modeling of the Ala Wai Canal (U.S. Army Corps of Engineers, 2001 and 2005) was calibrated to the limited data of the 1967 event on Palolo Stream and Manoa-Palolo Drainage Canal. At the time of the Validation study, the Makiki and Kanaha Streams did not have any calibration or gaged data to aid in calibration or model comparison but as they are mostly concrete lined channels, the n-values were deemed stable. Calibrated n-values are assumed to also account for any sediment or debris “bulking” during those storm events.

The Ala Wai Watershed contains several active and inactive USGS Stream Gages, but the data during the historic flood events was only reported on a daily interval. Due to the relatively rapid rise and fall of the flood wave (typically the flood wave passes within a few hours) the daily stage and/or discharge data was not adequate for calibration. However, Appendix A2 of the 2017 Feasibility Report (see Addendum A) did provide some comparison data for three of the USGS stream gage stations in effect during those events. There was at least one difficulty with the data which was that the gages are operated using a gage datum that does not correspond to a known datum (e.g. mean sea level) and so for the previous study an approximation of the gage datum had to be made to compare with the HEC-RAS model datum (i.e. LMSL). As stated in the Appendix A2 of the feasibility report, the approximation was made based on information provided by the USGS at their gage locations and the elevation data of the nearest HEC-RAS model cross-section. The Appendix A2 states that it was estimated for the feasibility 1D modeling that the conversion had a 1-foot error and that an additional difference of +/- 0.7 foot would result from model error and USGS rating curve error. The discharge value comparison from Appendix A2 is based on common discharge values from the station rating curves and the HEC-RAS model results at that location. The results from the 2020 Validation Study showed that the water surface elevations compared relatively closely with those of the previous study and are within the expected error of +/- 1.7 feet. In addition to that limited data, some qualitative comparisons were made to ensure that the model was producing reasonable results, and that can also be found in the Validation Study Hydraulic Report in Addendum C.

3.4.2. Calibration

As the MMC hydraulic model from the Validation study was used as our base model, and there were almost no changes to the set n-values and channel debris that was used to calibrate the model for the Validation Study, it was assumed that the model would still calibrate to acceptable levels for this GRR update. The qualitative reviews of the 2004 storm extents from the Validation Study still hold for this model.

The updated GRR hydraulic model was verified by looking at the best data currently available: the USGS rating curves for 4 gages in the modeling extents. The USGS rating curves were entered into the 0.2% AEP flood event for the FWOP model, so that the full extent for the curves could be compared to modeled output.

Two of these gages, the Manoa Stream at Woodland USGS gage 16241600 and the Pukele Stream gage 16244000, have actual surveyed in gage datum elevations, so converting their gage stage vs discharge rating curves into an elevation vs discharge rating curve was easy and accurate. For these two locations, the current USGS rating curve was utilized as the new survey elevation was available to update those easily and accurately. According to an email from USGS Field Operations Chief in Honolulu, the provisional gage datum elevation for Manoa at Woodlawn gage is 135.44 ft msl with a shift-adjusted rating curve, point of zero flow is at 2.49 ft gage datum, so a shift-adjusted gage datum of 137.93 msl (May, 2022). The gage datum elevation for Pukele gage is 344.78 ft msl. The Pukele elevation is posted to the USGS station webpage, but the Manoa at Woodlawn elevation is considered preliminary and was received from coordination with USGS personal.

The other two gages, the Makiki Stream at King Street USGS gage 16238000 and the Manoa-Palolo Canal at Moiliili USGS gage 16247100, have estimated gage datum elevations from topo. As referenced in the above section, the Validation Study estimated what those gage datum elevations were, created elevation vs discharge rating curves for those. Those derived rating curves from the Validation Study were used for these two gages.

The Makiki Stream at King Street observed (estimated) rating curve and the modeled rating curve for that cross section, Makiki Lower RS 3062, is shown below Figure 3-16. The lower portion of the rating curves match well, especially considering the estimate of the gage datum. While the upper portion of the rating curves deviate quite a bit over an elevation of about 13.5 ft msl, investigation into the model results showed that this cross section is under backwater influence from the Philip Street bridge for the large flows.

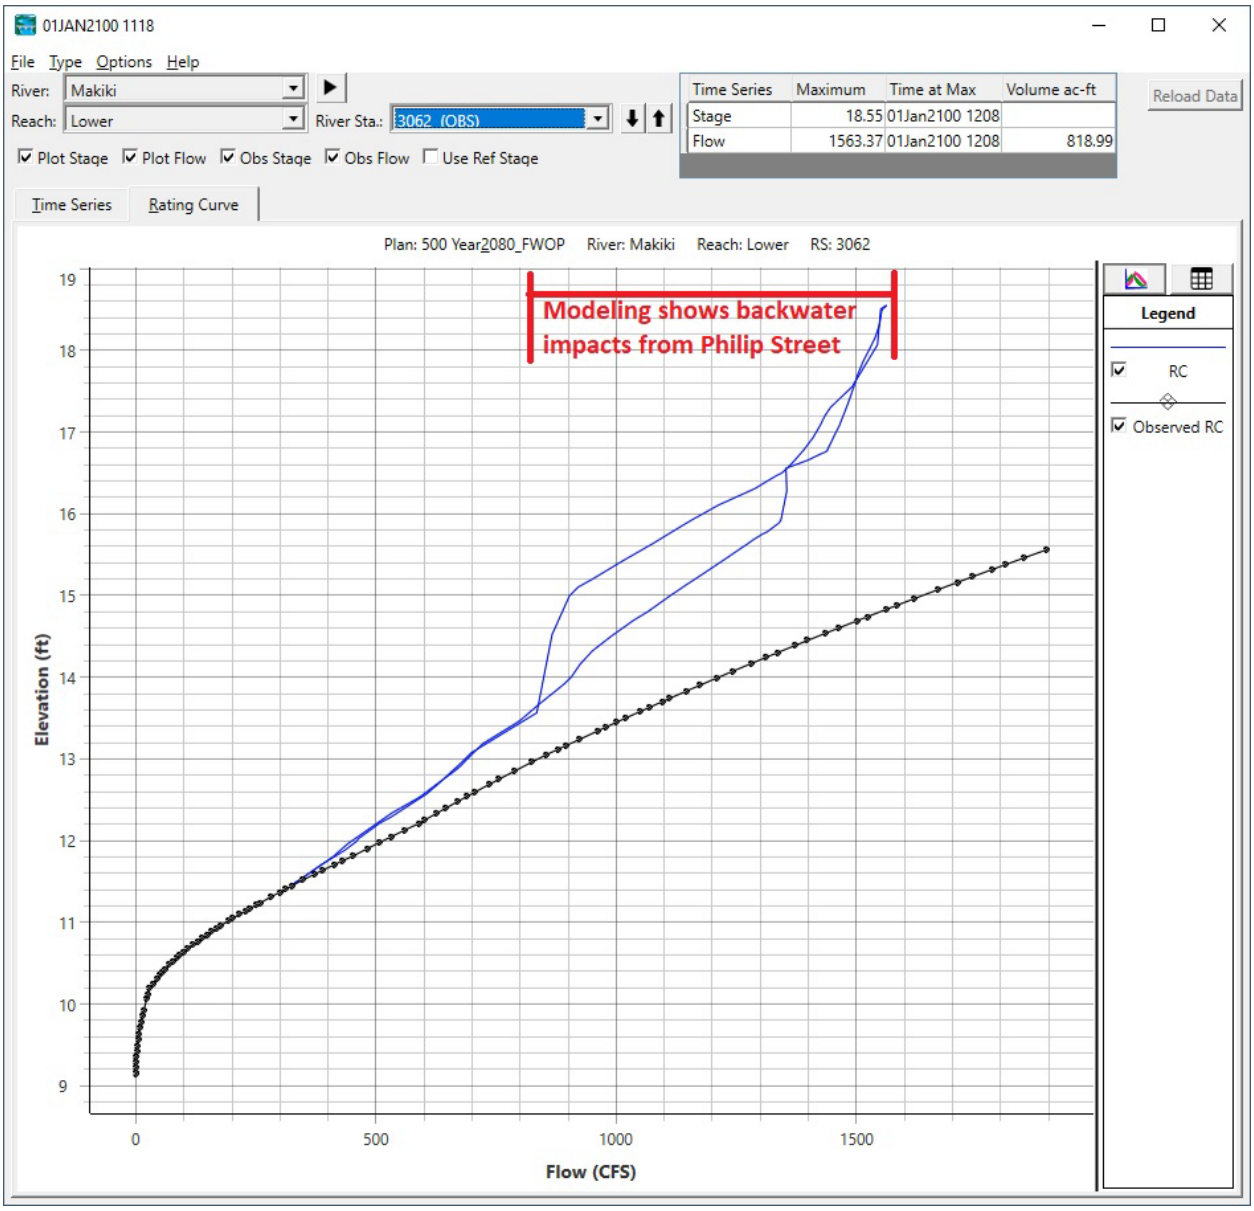

Figure 3-16: Makiki Stream at King Street Modeled vs Observed Rating Curve

The Manoa-Palolo Canal at Moiliili observed (estimated) rating curve and the modeled rating curve for that cross section, Palolo Lower RS 3201, is shown below in Figure 3-17. The rating curves match well, especially considering the estimate of the gage datum.

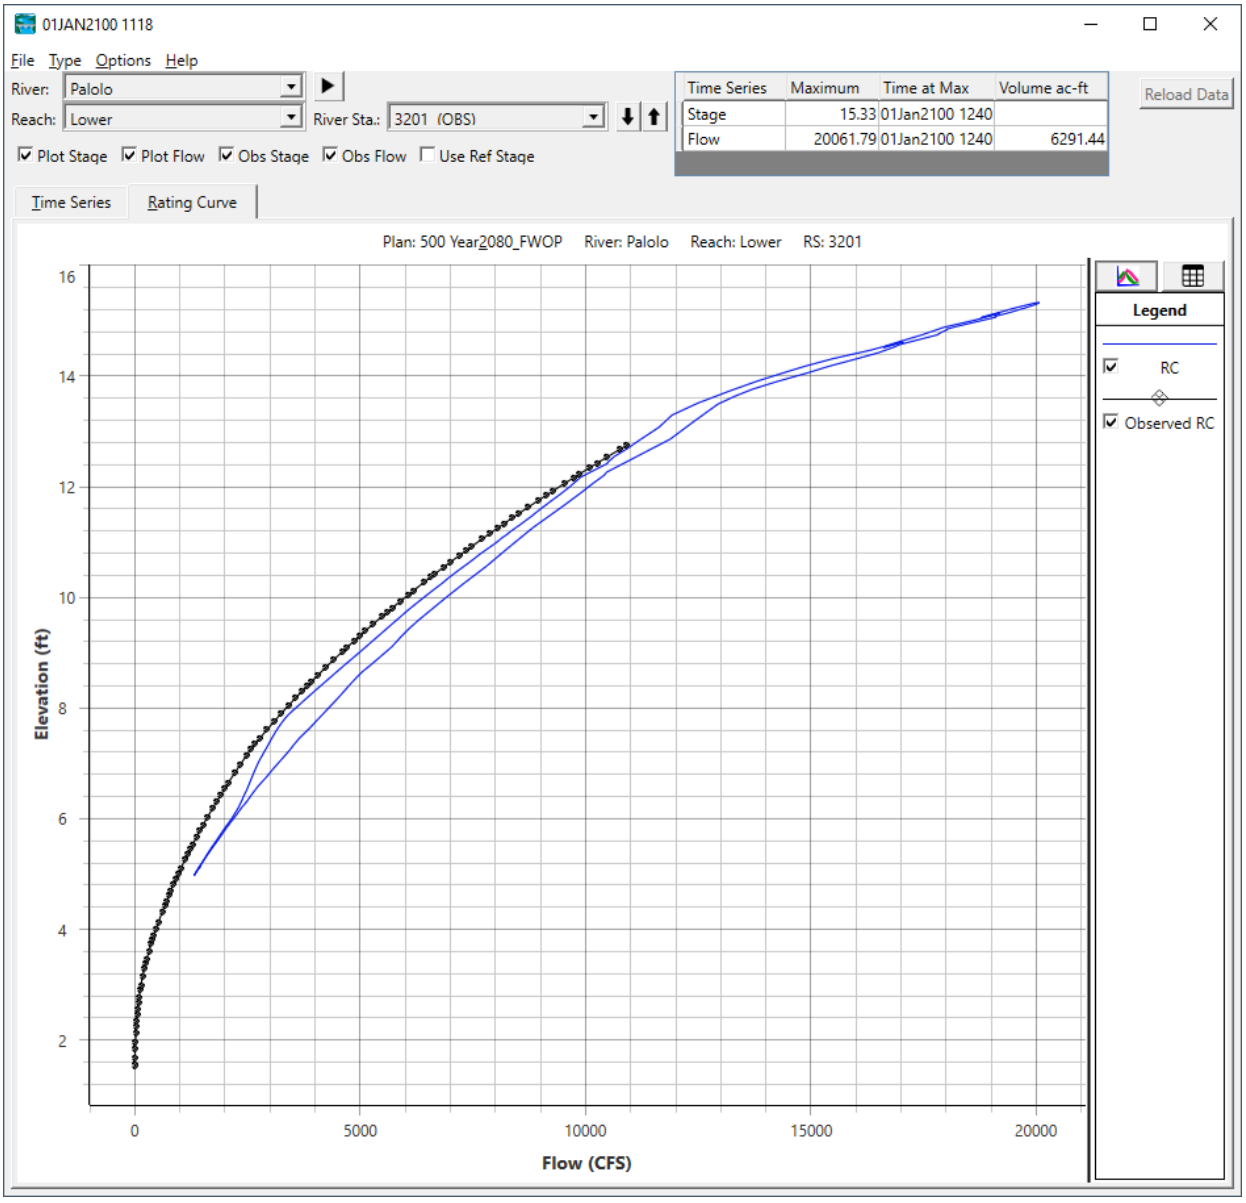

Figure 3-17: Manoa-Palolo Canal at Moiliili Modeled vs Observed Rating Curve

The Manoa Stream at Woodlawn observed (calculated) rating curve and the modeled rating curve for that cross section, Manoa Main RS 8016, is shown below in Figure 3-18. The rating curves match quite well for the entire stretch of the USGS rating curve. The updated GRR model rating curve extends beyond the USGS rating curve and shows the results of all the overland flooding that occurs at Woodlawn and flow leaving the channel.

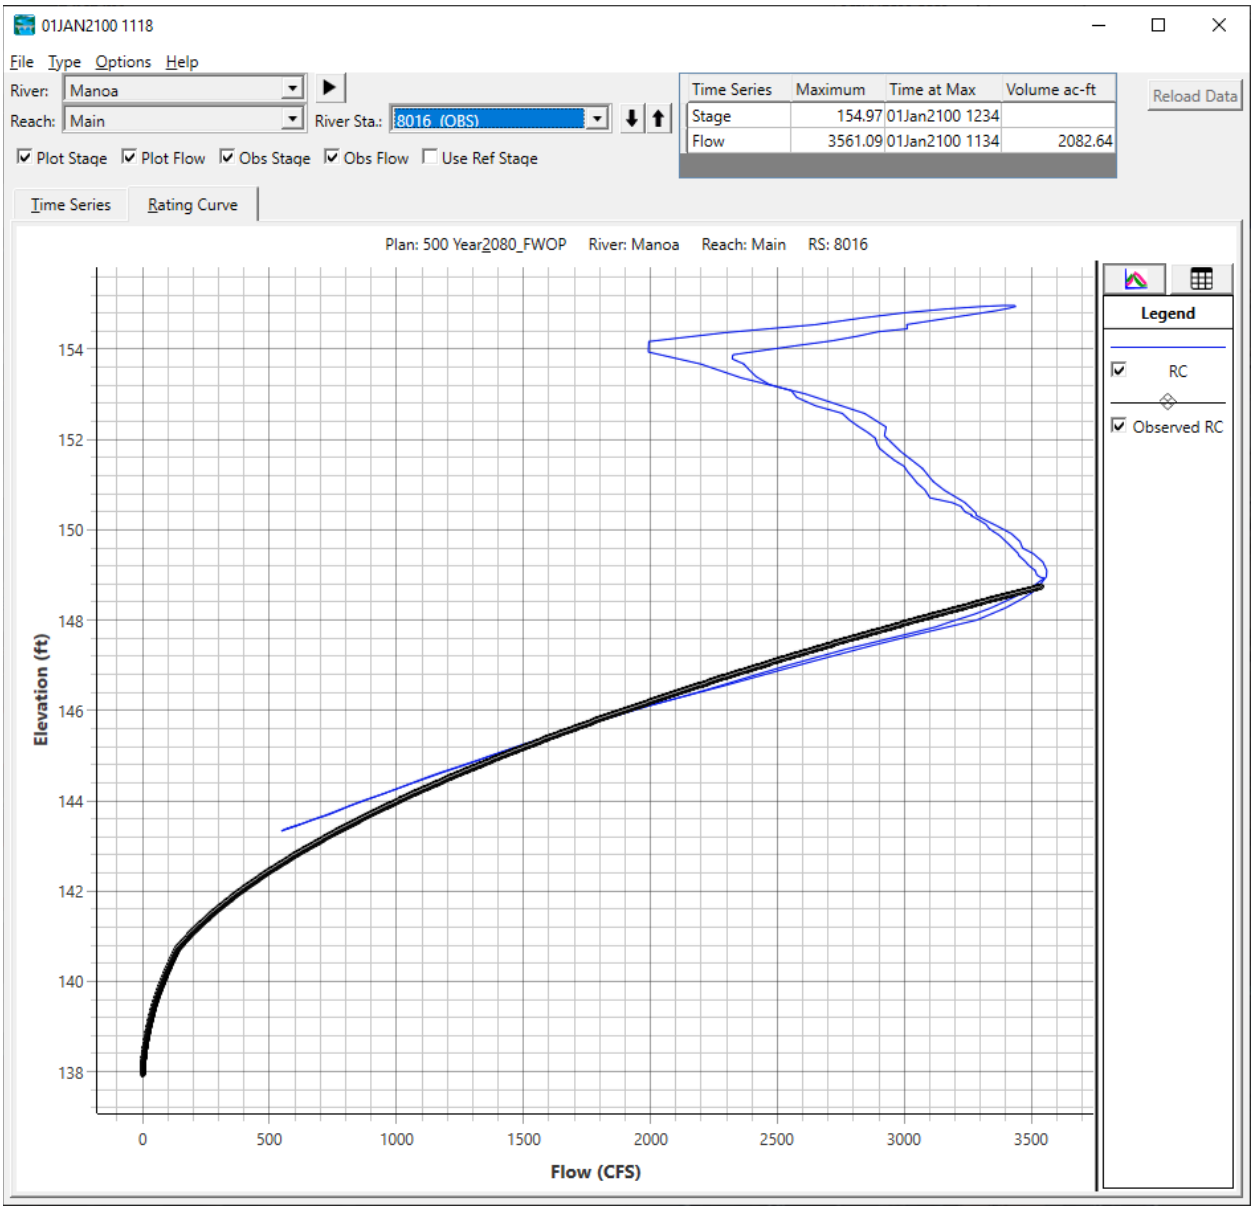

Figure 3-18: Manoa Stream at Woodlawn Modeled vs Observed Rating Curve

The Pukele Stream observed (calculated) rating curve and the modeled rating curve for that cross section, Pukele Tributary RS 3406, is shown below in Figure 3-19. The rating curves match well for the upper portion of the USGS rating curve. The updated GRR model rating curve starts a little higher due to the base flow needed to get the model to run stable in the steep slopes of the upper watershed, and the updated GRR modeled rating curve extends beyond the USGS rating curve.

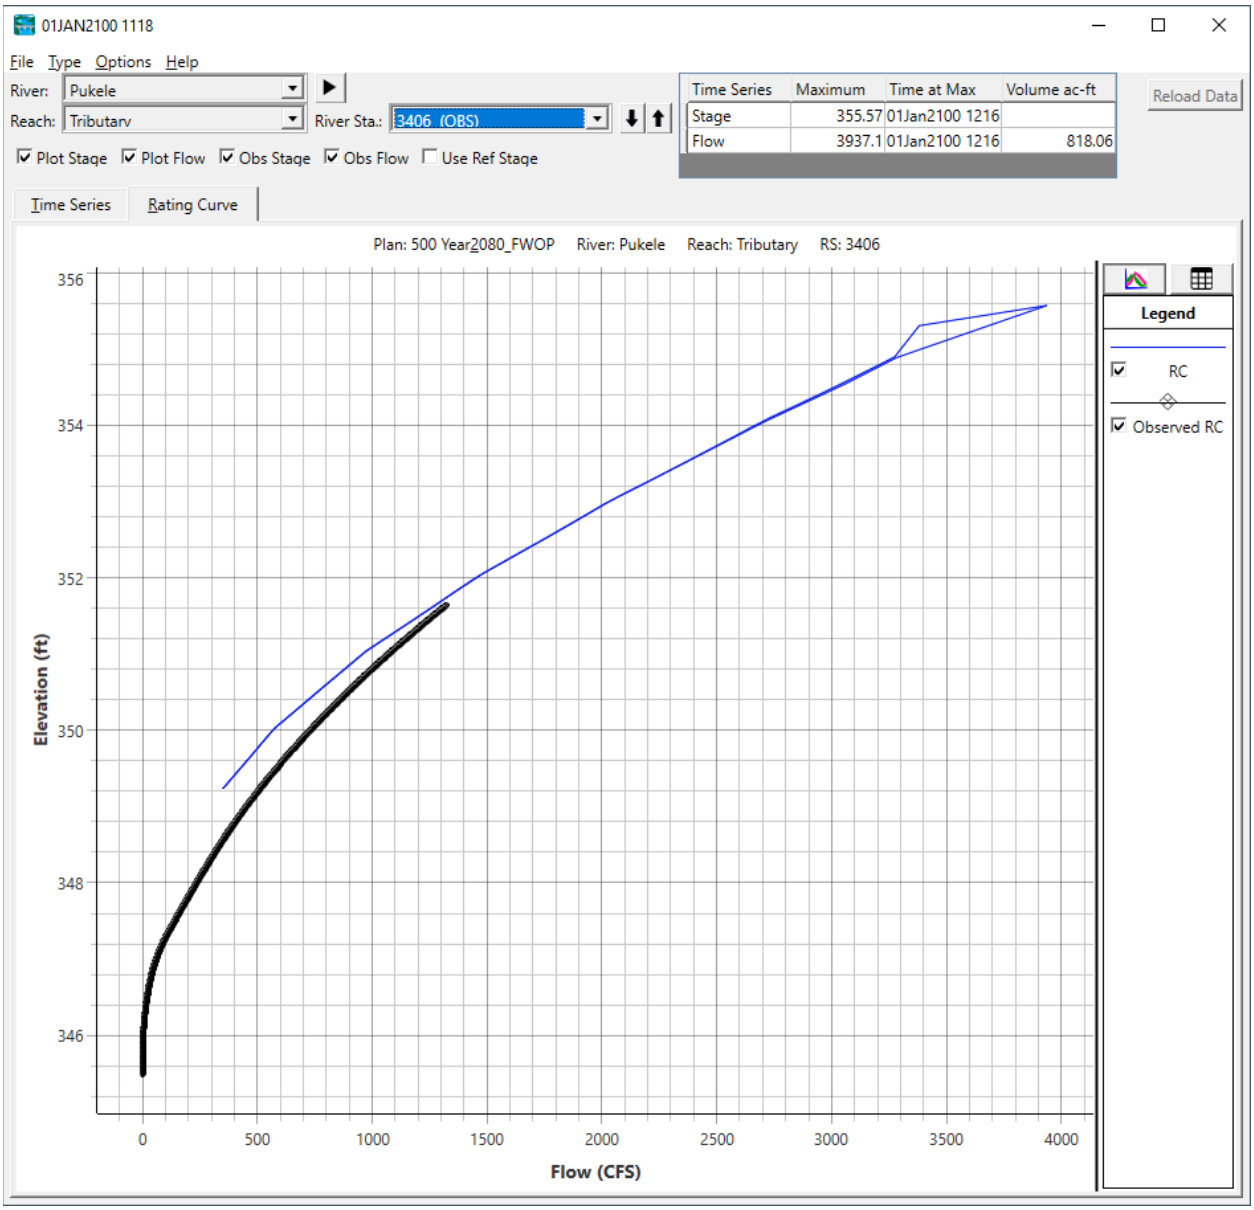

Figure 3-19: Pukele Stream Modeled vs Observed Rating Curve

From this analysis, the updated GRR hydraulic model was deemed appropriate for use in the Ala Wai Watershed Flood Study.

3.4.3. December 2021 Kona Low Validation

The model was validated with the December 2021 Kona Low storm event. The event was approximated as about a 20% AEP (5 year) flood event, which is approximately the channel

design capacity of most of the rivers in the Ala Wai basin. The discharges that were calculated from the HEC-HMS model run using the precipitation from this event, which are described in Section 2.2 above, were input and run with the current version of the Ala Wai HEC-RAS model.

The model matched the observed flood data collected, some photos and measured flood depths, throughout the model, even the lower Makiki Stream flood area. The flood elevations in the 2D area matched photos/observed flood depths in the areas where some data existed, especially near Fern Street in the McCully/Moiilili neighborhood near the Makiki Stream. The model does show slightly more overland flow going down the two-dimensional area south of Kanaha Stream than actually occurred, but that is because for the 20% AEP event, some flood waters would be captured through the storm sewers, which is not accounted for in the current HEC-RAS model version. The model is expected to be better calibrated for the 10% AEP (10 year) and larger flood events, where storm sewers would be at full capacity and not impact modeling results and where the minimum baseflows required for model stability would have much less of an impact.

3.5. Downstream Boundary Conditions

As a watershed that drains to the ocean, sea level becomes the tailwater condition that affects the capacity of fluvial channels to drain. The variation of sea level over the lifetime of the project must be understood to ensure project performance will provide the predicted benefits and minimize overall project costs. This discussion focuses on the analysis performed to select an appropriate tailwater condition that will be used in modeling of fluvial flood events and mitigation measures for such events.

Multiple alternative levels of analysis exist which may be necessary to determine the appropriate coincident probability of a fluvial storm occurring with any given sea level:

1. The Simplest: Begin with a correlation analysis of a tidal gage and an inland gage (with tidal influence). Plot the events on a flow-frequency vs tide-frequency chart to determine IF there is a correlation and, if one exists, what that correlation is. If there is no correlation, choose an appropriate tide level to use as your downstream boundary condition. Choose either the Mean Higher-High Water (MHHW) or "King Tide", whatever the correlation and tide level sensitivity indicates is appropriate.

2. The Safe: If the above correlation determines there IS a correlation of tidal events with inland storms, develop a table of runs for tidally influenced boundary conditions and fluvial/inland influenced boundary conditions, incorporating the correlation findings, e.g. a 20% AEP inland storm with a 99% AEP tide level, a 4% AEP tide level with a 50% AEP inland storm, etc. The results should be included in a mixed populations joint-probability analysis (EM1110-2-1415 Ch 10). This analysis will result in a frequency curve that includes the effects of tide levels and water surface runoff.

3. The Complex: A full coincident probability analysis is required if there is a large contribution of flooding from tidal events (i.e. a strong correlation). This is especially true for a Coastal Storm Risk Management Study. This analysis includes running every tide level

frequency event against every inland storm frequency event, and running every inland storm against every tide frequency. The results are then analyzed within HEC-SSP to create a comprehensive frequency curve that incorporates the full suite of possibilities.

The PDT began with the "simplest" analysis to examine the potential for correlation between available tidal gage data and inland gage data, with expectation of progressing to more complex analyses if a correlation was found.

3.5.1. Historical Hydrologic Data Availability

There are six active streamflow gages in the watershed. The Manoa-Palolo Drainage Canal at Moiliili gage has a continuous peak streamflow record of 53 years. It has experienced major flooding on three occasions since 1967. The Pukele Stream gage, in the headwaters of the Palolo Stream, has a peak streamflow record of 69 years, with the last local storm event in 1930. The Waihi Stream gage and Waiakeakua Stream gage, in the headwaters of the Manoa Stream, have discontinuous peak streamflow records dating back to 1915. The remaining two gages have limited streamflow data: Makiki Stream at King Street has 12 years of peak streamflow data while Manoa Stream at Woodlawn Drive has only 8 years of data. Of the six gages, four have associated flood stages with the NWS as seen in Table 3-4 and Figure 3-20.

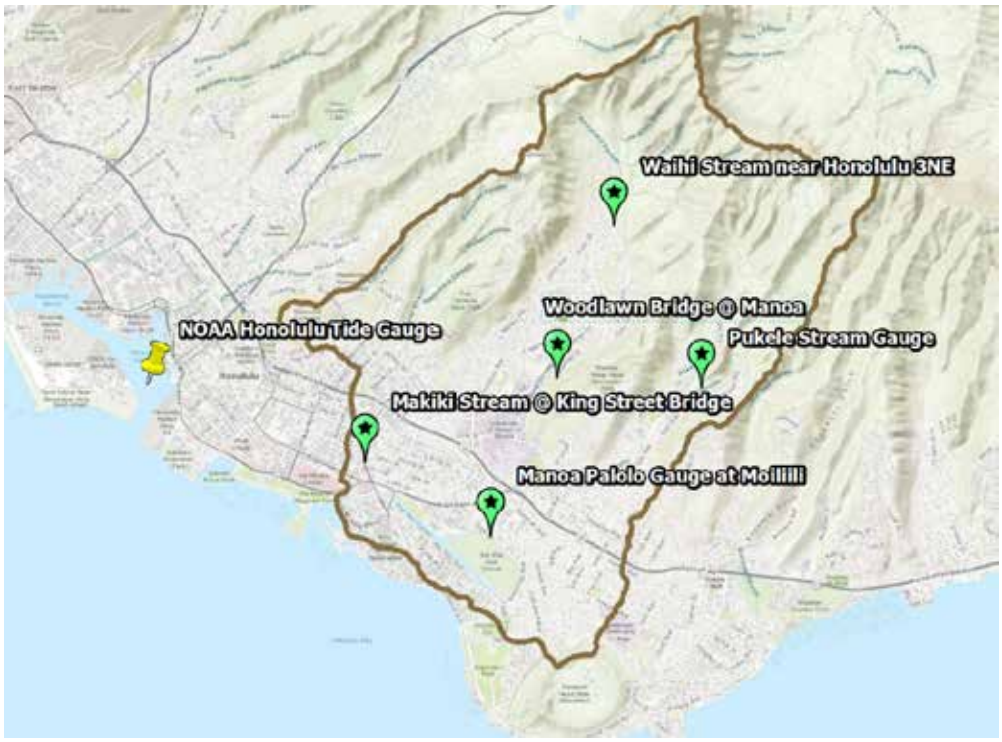

Figure 3-20: Gage locations relative to Ala Wai Watershed

Based upon available records, there is no significant trend in historic streamflow in the major tributaries to the Ala Wai canal, the Makiki Stream and Manoa-Palolo canal. See Figure 3-21 and Figure 3-22, below for annual peak discharges for the available period at these two gages respectively. With the exception of the historic events described in Section 1.3.2, peak discharges have remained generally constant.

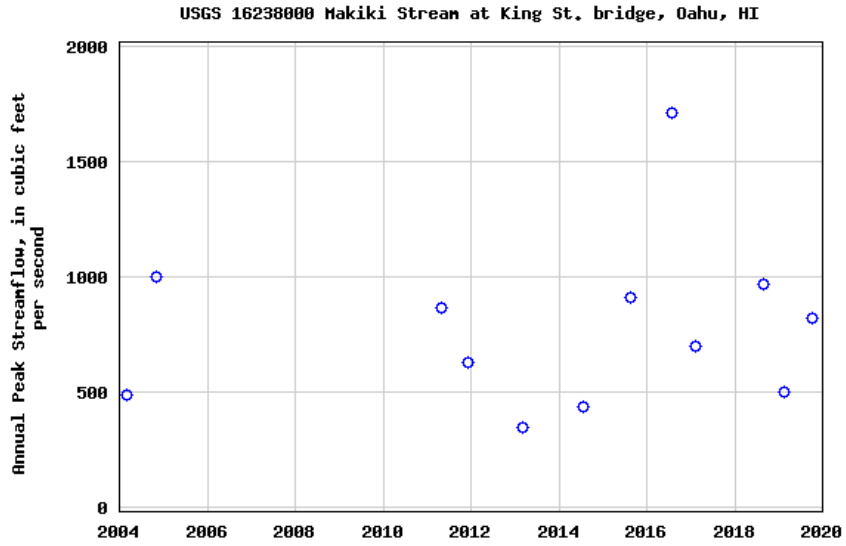

Figure 3-21: Annual Peak Discharge, Makiki Stream at King Street (USGS)

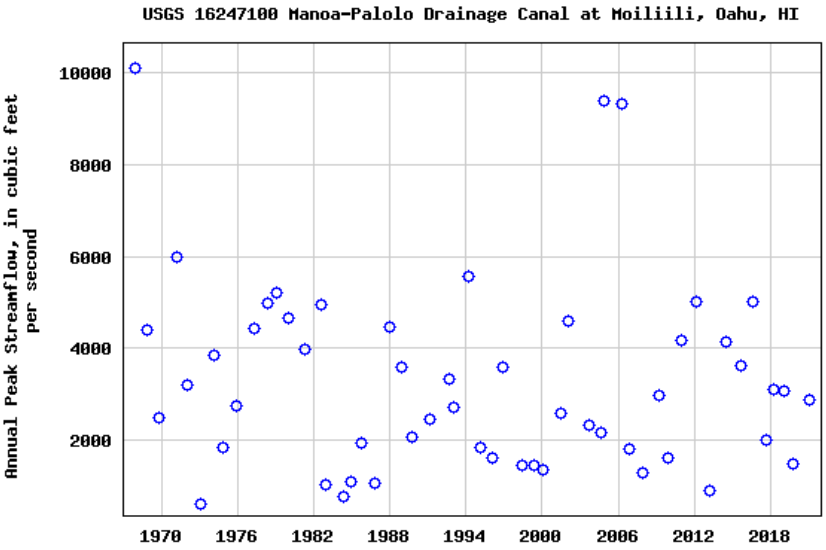

Figure 3-22 Annual Peak Discharge, Manoa-Palolo Canal (USGS)

Based upon global trends, it is anticipated that the frequency of the extreme storm events and droughts will likely increase in the future. Runoff magnitude of extreme events may also increase. Overall future Hawaiian precipitation totals will be either slightly drier or experience little change (State of Hawaii, n.d.). As the global trends of increased air and ocean temperatures promote the spread of invasive species, which generally decrease canopy and increase imperviousness, higher discharges and flashier flood events are expected to occur in future storms, contributing to greater damages and life safety risks (Giambelluca T. , 2012).

While the focus of this study is on riverine flooding, the future trends of sea level rise due to climate change should be noted, as tidally-influenced waters can impact the downstream study area. Sea levels around Hawai'i have risen 10 inches since 1950 and are rising faster at about one inch every four years (SeaLevelRise.ORG, n.d.). Based upon current models, Hawai'i will experience the highest rates of sea level rise on the planet, partially due to the gravitational effects disproportionately affecting the tropical Pacific (Tetra Tech and the State of Hawaii DLNR, 2017). An analysis of sea level change relative to assumptions necessary for this study are discussed further below.

Stationarity, or the assumption that the statistical characteristics of hydrologic time series data are constant through time, enables the use of well-accepted statistical methods in water resources planning and design in which future conditions rely primarily on the observed record. However, recent scientific evidence shows that—in some places, and for some impacts relevant to the operations of the U.S. Army Corps of Engineers—climate change and human modifications of the watersheds are undermining this fundamental assumption, resulting in non-stationarity. Using the gage at Manoa-Palolo Canal with 53 years of continuous data, the USACE Non-Stationarity Detection Tool did not find evidence of non-stationarity and did not find a monotonic trend in stationary flow records (USACE Non-stationarity Detection Tool). This finding will allow the USACE to assume stationarity in hydrologic analyses moving forward. Additional information regarding the non-stationarity analysis is included in Appendix H on Climate Change Analysis. It is noted that the small watershed size and rapid time to peak may affect the recording of true peak values used in this analysis, with unknown effects on the analysis of long-term trends.

3.5.2. Tidal-Fluvial Assessment

To run the unsteady hydraulic model of the Ala Wai Canal and its tributaries with a set of hypothetical events, boundary conditions are established for the upstream reaches and the mouth of the Ala Wai Canal. It was necessary to perform an assessment to establish the coincident still water level that might be expected to occur during an inland rainfall event.

For this assessment, the fluvial gages at Manoa-Palolo Drainage Canal at Moiliili (USGS 16247100) and Makiki Stream at King St. bridge (USGS 16238000) were used to compare historical fluvial events with the coincident still water level data from the NOAA tidal gage at Honolulu (ID: 1612340). The Manoa-Palolo and Makiki gages are the most downstream gages on these primary tributaries to the Ala Wai Canal, each being approximately 0.6 miles upstream from their respective confluence with the canal. For the Manoa-Palolo gage, annual peak data is available from 1967-2021, but detailed (15-minute) discharge records are only available from October 1, 1999, to present. For the Makiki gage, annual peak values are available for the 2004

and 2005 Water Years, and for the period of 2011-2020, with more detailed data available from February 2010 to present.

The Honolulu tidal gage was chosen as the best comparable site to the Ala Wai watershed, being the closest tidal gage to the Ala Wai canal site approximately 2 miles from the mouth, and it is located within the Honolulu Harbor, creating similar tidal conditions to the mouth of the Ala Wai canal which empties into the Kahanamoku Lagoon. The Honolulu tide gage has monthly maximum and minimum elevation records beginning in 1927 and hourly verified values since 1921. The only other gage on Oahu is on the opposite (windward) side of the island, therefore would experience different coastal flow conditions, in addition to being distant to the Ala Wai watershed. The Honolulu gage, being very close in proximity and having very similar coastal geometry is deemed the best available information and suitable as a proxy to the mouth of the Ala Wai canal that is the downstream boundary for the HEC-RAS model. It is acknowledged that minor differences may occur in the immediate vicinity of the Ala Wai Canal that are not perfectly represented by the Honolulu tide gage used to approximate the real tide elevations occurring at the downstream boundary. However, no wave models or additional data are currently available to quantify the relative differences that may occur between the proxy gage and the project site. It is expected that the differences are small and impose only a minimal risk of error in the potential determination of the downstream boundary condition. Therefore, circulation and/or wave modeling is deemed unnecessary given the suitability of the available gage data in such close proximity to the project.

NOAA has also published frequency still water level elevations for the 99%, 50%, 10% and 1% AEP events (also known as Extreme Water Levels, EWL) based upon the long historic record of the Honolulu gage from 1905-2010 as shown in Figure 3-23 (note that column labeled “2018” are “projected exceedance probability levels and tidal datums assuming continuation of the linear historic trend” and is not used here) (Zervas, 2013). Additional event AEPs are also listed as part of the USACE Sea Level Calculator output for the Honolulu gage included as both metric and English units for reference, shown in Table 3-5. Per NOAA documentation, the data set of historical values used to determine the EWL values included storm tides, equal to the “combination of the astronomical tide, the storm surge, and limited wave setup caused by breaking waves,” but excluding wave runup. The published EWL values were used to interpolate estimated AEP for still water level elevations that occurred during the approximate time of the flood events recorded by the fluvial gages.

To determine correlation between extreme water level and peak surge events, an analysis compared the non-tidal residual (NTR) from the Honolulu tide gage to the Makiki and Manoa-Palolo stream gage flows. The hourly Honolulu data gage was de-trended by: (1) subtracting the predicted tide from the observed water level ("residual"), (2) Long-term sea level rise (1.5 mm/yr for Honolulu Harbor) was removed from the residual for the time series relative to the 1992 base year, and (3) Seasonal variability as documented by the NWS for the Honolulu gage (https://tidesandcurrents.noaa.gov/sltrends/sltrends_station.shtml?id=1612340) was also subtracted to complete the NTR calculation. The 15-minute stream gage values were converted to hourly data for comparison to these NTR values. Peak over threshold values were manually selected for the stream gages; 1000 cfs and 350 cfs were set as the thresholds for peak flows for the Manoa-Palolo and Makiki stream gages respectively based upon inspection of the values and historical annual peaks. A reciprocal Peak Over Threshold analysis was also performed by inspecting the NTR values and selecting all peaks greater than 0.599 meters, equivalent to two standard deviations above the mean NTR value. Assistance was also received from the Engineering Research and Development Center (ERDC), who performed a separate comparison of threshold values utilizing a statistical package, Storm Simulation Stochastic Simulation Technique (SST), to validate the manually selected data. SST was also used to evaluate the sensitivity of certain parameters such as the coincidence time used to establish the independence of instances above the threshold value as well as the threshold value itself, and calculate statistical correlation measurement between the peak discharges and NTR.

Table 3-6 presents the results of this statistical comparison and relative sensitivity analyses performed by ERDC utilizing the statistical package. SST utilizes observations or simulations from extreme storm events in the form of a partial duration series (PDS) to simulate multiple sequences or life cycles of storm activity and their corresponding responses. The Kendall rank correlation coefficient ("Kendall's τ" or "Kendall's Tau) is a non-parametric measure of relation-ships between two sets of data, where the resulting value of the analysis varies from 0 to 1, wherein 0 means no relationship and 1 is a perfect relationship. The p-value is the measure indicating the level of significance for the hypothesis test that the Kendall's τ is an accurate representation of the correlation.

Table 3-6 Statistical results of correlation analysis

Station	Paired Values Source	Variable	Threshold Q (CFS)	Threshold NTR (m)	Lambda (events / year)	Coincidence Time (days)	Kendall's Tau τ	p-value
Makiki	Manual	Q	350		3.0	2	0.044	0.733
Makiki	SST	Q	149		4.7	1	0.037	0.657
Makiki	SST	Q	155		4.4	1	0.041	0.635
Makiki	SST	Q	149		4.7	2	0.049	0.560
Makiki	SST	Q	155		4.4	2	0.050	0.566
Makiki	Manual	NTR		0.6	13.6	2	0.023	0.645
Makiki	SST	NTR		0.616	2.2	1	0.118	0.260
Makiki	SST	NTR		0.382	8.4	1	0.015	0.824
Makiki	SST	NTR		0.616	2.2	2	0.187	0.073
Makiki	SST	NTR		0.382	8.4	2	0.013	0.846
Manoa-Palolo	Manual	Q	1000		3.2	2	0.045	0.582
Manoa-Palolo	SST	Q	1330		1.5	1	0.018	0.868
Manoa-Palolo	SST	Q	281		8.6	1	0.072	0.121
Manoa-Palolo	SST	Q	1330		1.5	2	0.061	0.564
Manoa-Palolo	SST	Q	281		8.6	2	0.089	0.056
Manoa Palolo	Manual	NTR		0.600	11.4	2	0.035	0.449
Manoa-Palolo	SST	NTR		0.616	2.2	1	0.240	0.019
Manoa-Palolo	SST	NTR		0.382	8.4	1	0.016	0.767
Manoa-Palolo	SST	NTR		0.616	2.2	2	0.250	0.015
Manoa-Palolo	SST	NTR		0.382	8.4	2	0.015	0.782

As indicated in Table 3-5, the maximum Kendall's τ value is 0.250 for one scenario relating the high NTR to Manoa-Palolo discharges, but it does not exceed the typical value of 0.3 typically preferred as in indication of correlation between parameters. However, this scenario and similar τ value of 0.240 were calculated using a high NTR threshold resulting in the average events per year being 2.2 which is likely too extreme. The more likely scenarios (having events per year of 8.4) achieved a Kendall's τ less than 0.02 and a high p-value greater than 0.75, suggesting no dependence between the peak flows and the NTR. Because the NTR and peak stream flows are considered independent, no bivariate analysis on these parameters was deemed necessary.

For the common period of record for the Honolulu and Manoa-Palolo gages since 1967, of the 51 recorded annual peak values with corresponding tidal records, 12 of those events had recorded daily maximum still water levels that exceeded a 99% AEP elevation. See Figure 3-17. Of those 12 events, the highest daily still water level value had approximately a 59% AEP, with the remaining 11 events ranging from approximately 70% AEP to 99% AEP. The remaining 39 events all had maximum daily elevations less than the 99% AEP event. Conversely, the monthly maximum Honolulu gages were compared to the available flow data for the Manoa-Palolo gage available starting in 1999. In that period, 27 still water level events exceeded the 99% AEP value, but of those events, only 7 flood events occurred that exceeded the 99% AEP discharge, with the greatest flow having an AEP of approximately 70%.

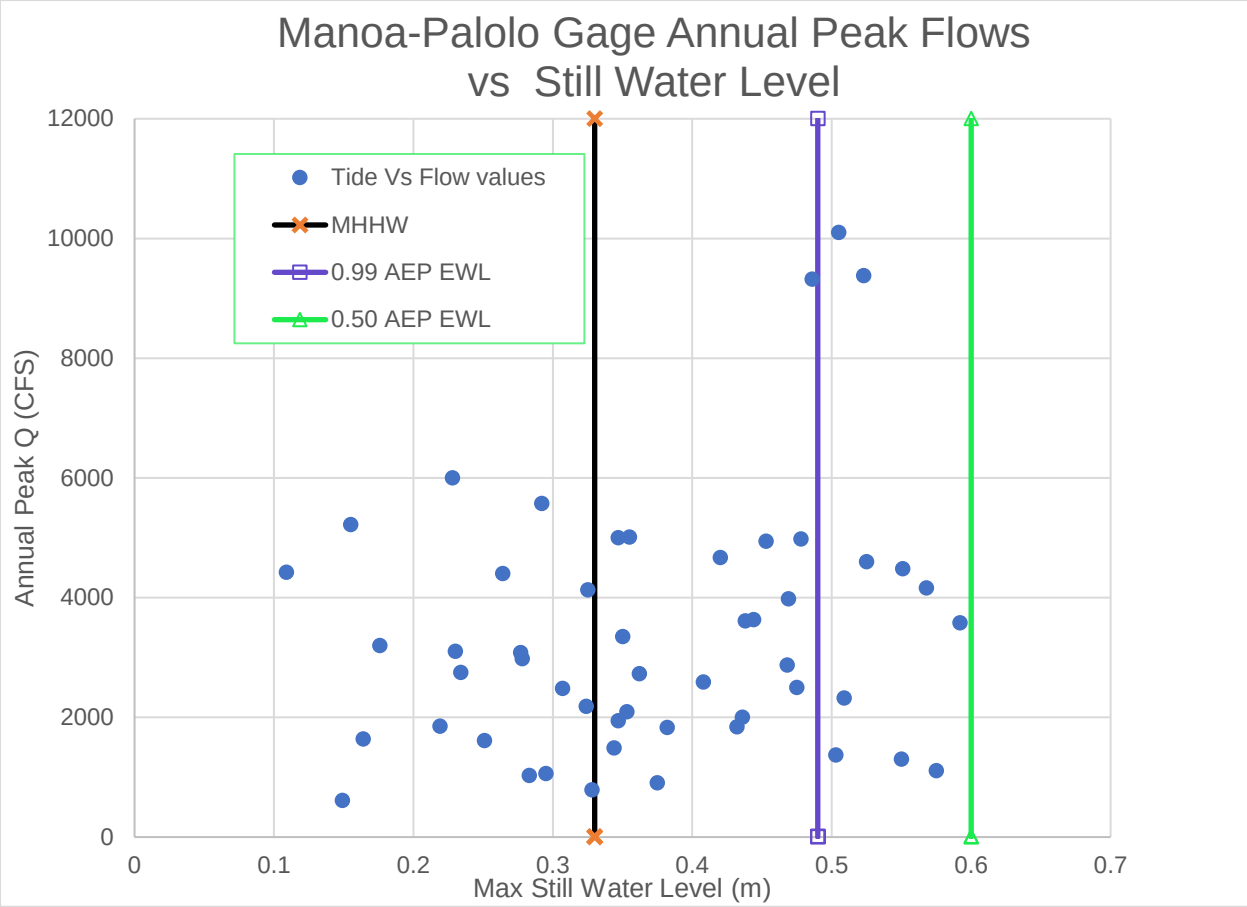

Figure 3-24: Manoa-Palolo Gage Annual Peak Flows vs Honolulu Gage Still Water Level

Performing a similar analysis of Makiki gage flow data, only 10 annual peaks were available for comparison to the Honolulu tide data. See Figure 3-21. Of those 10 events, 2 events had maximum daily still water levels that exceeded the 99% AEP, with the maximum having an AEP of approximately 69% and the other having an approximately 94% AEP. Of the 18 tidal events that exceeded the 99% AEP height that occurred within the period of record of the Makiki gage, only 2 events had discharges that exceeded the 99% AEP discharge, with the maximum having an approximately 53% AEP and the other having approximately a 66% AEP.

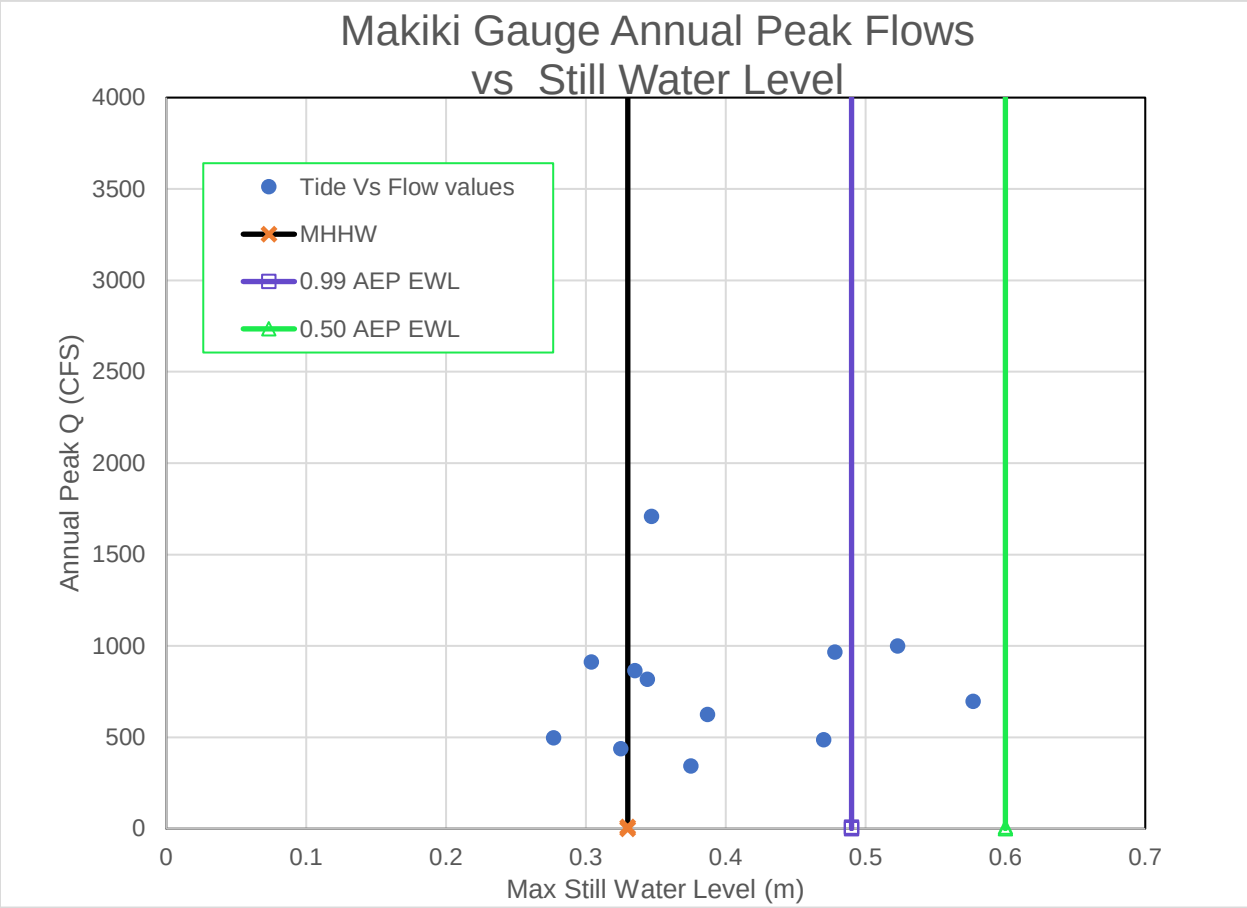

Figure 3-25: Makiki Gage Annual Peak Flows vs Still Water Level

It must be acknowledged that the above analysis omits the potential influence of waves that may occur in the immediate vicinity of the Ala Wai Canal that are not perfectly represented by the Honolulu tide gage used to approximate the real tide elevations occurring at the downstream boundary. No wave models or additional data are currently available to quantify the relative differences that may occur between the proxy gage and the project site. Due to the close proximity of the Honolulu tide gage to the project and similarity of hydrodynamic conditions (i.e., as both are in a protected harbor/lagoon), it is expected that the differences are small and impose only a minimal risk of error in the potential determination of the downstream boundary condition. Per the supporting documentation for the Honolulu tide gage and the methods for

determining the EWL, it states: "The extreme levels measured by the CO-OPS tide gages during storms are called storm tides, which are a combination of the astronomical tide, the storm surge, and limited wave setup caused by breaking waves" (NOAA, n.d.). Therefore, wave setup is at least somewhat partially considered in the statistical analysis determining the EWL value. Based upon local experience by POH personnel, waves are not observed to propagate into the Ala Wai Canal. As will be described later, the steepness of the watershed and the major tributaries limit the relative influence of the downstream boundary elevation, therefore the risk is deemed to be low that error created by omitting this wave component in the analysis will affect the outcome of screening and economic analysis of upstream mitigation measures. The risk may remain for evaluation of mitigation measures in the coastal floodplain, primarily measures at the Ala Wai canal.

The effects of tropical storms on inundation risk were not analyzed in the study based on the low occurrence rate in the historical hurricane records. A search of internet records indicates that the damages caused by Hurricane Iniki were attributed to coastal flooding caused by storm surge and wind damage and not attributable to heavy rainfall on the upland watersheds, which is generally consistent with the understanding that hurricanes that do make landfall on the Hawaiian Islands move too quickly over the relatively small watersheds to have time to drop large amounts of rainfall. It is acknowledged that Hurricane Lane did produce large amounts of rainfall as it slowly followed a track south of the islands but did not make landfall and no records of significant observed storm surge were found (Beven II & Wroe, 2019). Hydrometeorological Report (HMR) 39, a National Weather Service product examining the Probable Maximum Precipitation in the Hawaiian Islands (1963) also concluded “(1) the potential for extreme rains in hurricanes that affect the Hawaiian Islands is no greater than in some other types of cyclones, for example extreme kona storms. … (2) Storm types other than hurricanes because of their frequency are much more likely to produce the extreme rains.” Previous hurricane modeling studies considering the Honolulu – Waikiki area indicate storm surge is an isolated risk. In addition to this, as stated by Kennedy in the SWAN-ADCIRC documentation,

> *“The Waikiki (J) region of Honolulu, which has a very high concentration of tourists and large hotels, could experience flooding up to several kilometers inland for the strongest storms. This flooding would come not only from the ocean side, but through the Ala Wai Canal, which was created in 1928 to drain the low-lying areas that are now Waikiki. Wave runup computed with a bare earth assumption is predicted to penetrate significantly inland over much of this area, but would be limited by the large, strong buildings in this highly developed region. However, even in this worst case scenario, it must be noted that the flooding depths would be relatively small, and would only exceed 1 m at locations quite close to the shore. Tsunami inundation zones in this region are also large, but are less than still water surge inundation limits.”*

A study by the University of Hawaii (Li, Yamazaki, Roeber, Cheung, & Chock, 2018) also performed an analysis using a probabilistic approach to map coastal flood hazards including estimated effects of SLC and storm intensification and mapped resultant inundation maps for the 0.2%, 0.5%. and 1% events, which showed that the primary mode of flooding in Waikiki is from surge pushing up the Ala Wai canal and not from wave setup and runup. Significant coastal storm flooding does not occur until very low probability events. As such, further effort to

perform a hurricane track modeling to determine the associated wave and water levels is deemed beyond the scope of this effort since it is a fluvial flood risk study.

Based upon this examination of the relative concurrence of high runoff flows and high tide events, no relationship is apparent between these two phenomena. The majority of high runoff events occur when tidal elevations are less than the 99% AEP elevation: for the Manoa-Palolo watershed, 39 of 51 events (76%) occurred when still water levels were less than the 99% AEP EWL, and for the Makiki watershed 8 of 10 events (80%) that data was available for occurred when still water levels were less than that value. Although some events were observed greater than the 99% AEP levels, they were limited in number, and all were more frequent than a 50% AEP event, with the difference between the 50% AEP and 99% AEP EWL only being 0.11 m (0.36 ft or 4.33 inches). For the purposes of this project, the PDT has agreed that using the 99% AEP event still water level (adjusted for future sea level change) as the downstream model boundary condition would be representative, if not conservative, when evaluating the effects of various mitigation measures and scenarios.

3.5.3. Sea Level Trends

3.5.3.1. Sea Level Change

Global sea level change (SLC) is often caused by the global change in the volume of water in the world's oceans in response to three climatological processes: 1) ocean mass change associated with long-term forcing of the ice ages ultimately caused by small variations in the orbit of the earth around the sun; 2) density changes from total salinity; and most recently, 3) changes in the heat content of the world's ocean, which recent literature suggests may be accelerating due to global warming. Global SLC can also be caused by basin changes through such processes as seafloor spreading. Thus, global sea level, also sometimes referred to as global mean sea level (GMSL), is the average height of all the world's oceans.

Relative (local) SLC (RSLC) is the local change in sea level relative to the elevation of the land at a specific point on the coast. RSLC is a combination of both global and local SLC caused by changes in estuarine and shelf hydrodynamics, regional oceanographic circulation patterns (often caused by changes in regional atmospheric patterns), hydrologic cycles (river flow), and local and/or regional vertical land motion (subsidence or uplift).

Figure 3-19 shows historical relative sea level change (RSLC) at Honolulu for 1911-2022 as presented by the USACE Sea Level Tracker. Several metrics for sea level are presented: the monthly mean sea level (light blue), 5-year moving average (orange), and 19-year moving average (dark blue). It is apparent that over long time scales (19 years) mean sea level is steadily increasing. However, over shorter time scales mean sea level may increase or decrease (USACE ER 1100-2-8162, EP 1100-2-1). The monthly mean sea level (light blue) appears to go up and down every year capturing the seasonal cycle in mean sea level. The 5-year moving average (orange) captures the interannual variation (2 or more years) of sea level.

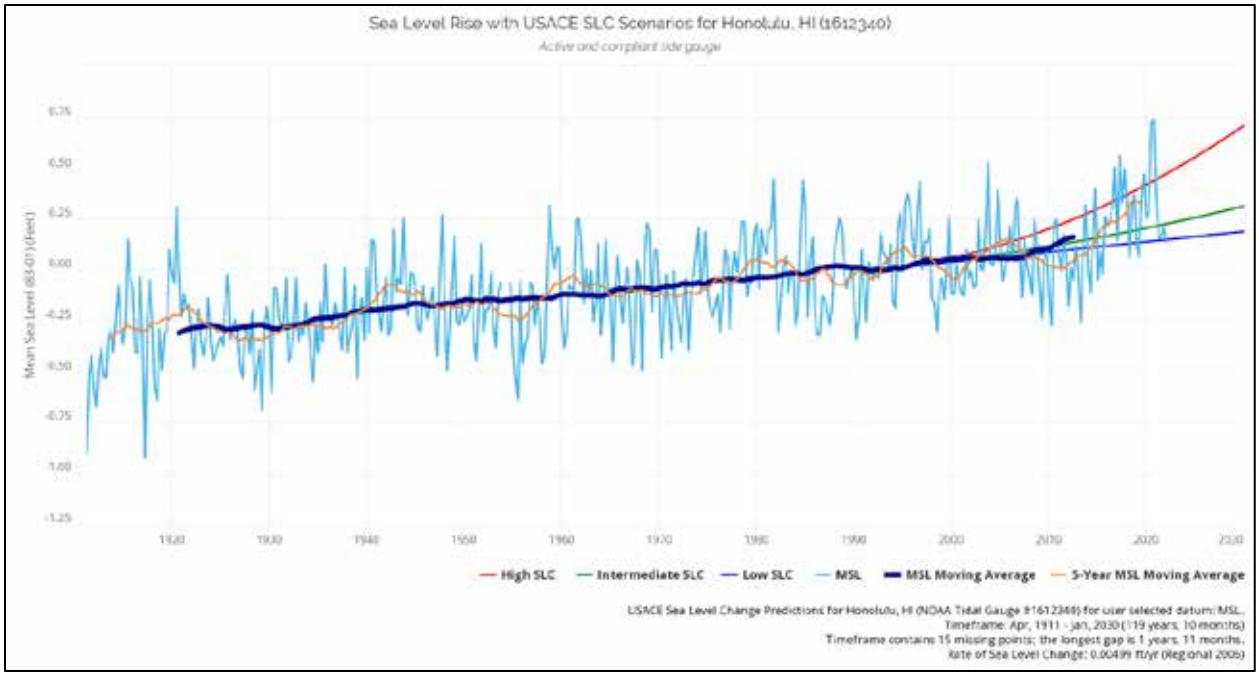

Figure 3-26: Historic Relative Sea Level Change 1911-2022 (US Army Corps of Engineers, n.d.)

To incorporate the direct and indirect physical effects of projected future sea level change on design, construction, operation, and maintenance of coastal projects, USACE has provided guidance in the form of Engineering Regulation, ER 1110-2-8162 (USACE, 2019). ER 1110-2-8162 provides both a methodology and a procedure for determining a range of sea level change estimates based on global sea level change rates, the local historic sea level change rate, the construction (base) year of the project, and the design life of the project. The analysis must include a baseline or "low" rate that is based on an extrapolation of the historical tide gage rate, equivalent to the RSLC, and intermediate and high rates that include future acceleration of GMSL. Historic RSLC for this study of 1.55 mm/yr (0.00492 ft/yr) is based on NOAA tidal records at the nearby Honolulu, HI gage. The "intermediate" and "high" scenarios are based on historic global sea level change and estimates developed by the National Research Council (NRC) for an Intermediate estimate (NRC Curve I), and a High estimate (NRC Curve III) representing the maximum expected sea level change.

All three scenarios are projected from the base year starting in 1992 (the midpoint of the current National Tidal Datum Epoch of 1983-2001). The Intermediate and High SLC projections use the following eustatic sea level rise (sea level change due to glacial melting and thermal expansion of sea water) equation:

$$E(t) = 0.0017t + bt^2$$

where E(t) is the eustatic sea level rise (in meters); t represents years from 1992; and b is a constant equal to 2.71E-5 (NRC Curve I), and 1.13E-4 (NRC Curve III) for the "intermediate" and "high" scenarios respectively. This equation assumes a global mean sea level change rate of +1.7mm/year.

For the purposes of this analysis, the construction base year of this flood risk management project is estimated to be the year 2030 and will have a 100-year design life and 50-year economic life. provides the estimated SLC values for these three scenarios.

Like Figure 3-22, Figure 3-23 represents the same trends but is focused on the period since 1980. Based upon examination of the historical trends for the Honolulu gage, it is apparent that the 19-year average and 5-year averages indicate a distinct trend of higher MSL than the historic rate. The 5-year MSL moving average trend shows greater amplitude than the 19-year MSL moving average, but it is also apparent that 5-year average oscillates about the computed Intermediate SLC curve and at times the 5-year moving average is near the High SLC curve. Although the 19-year average appears to trend higher in recent years, it too shows some oscillation about the Intermediate SLC curve. For the purposes of defining the future boundary conditions for modeling, it is anticipated that the Intermediate SLC curve will be the most appropriate.

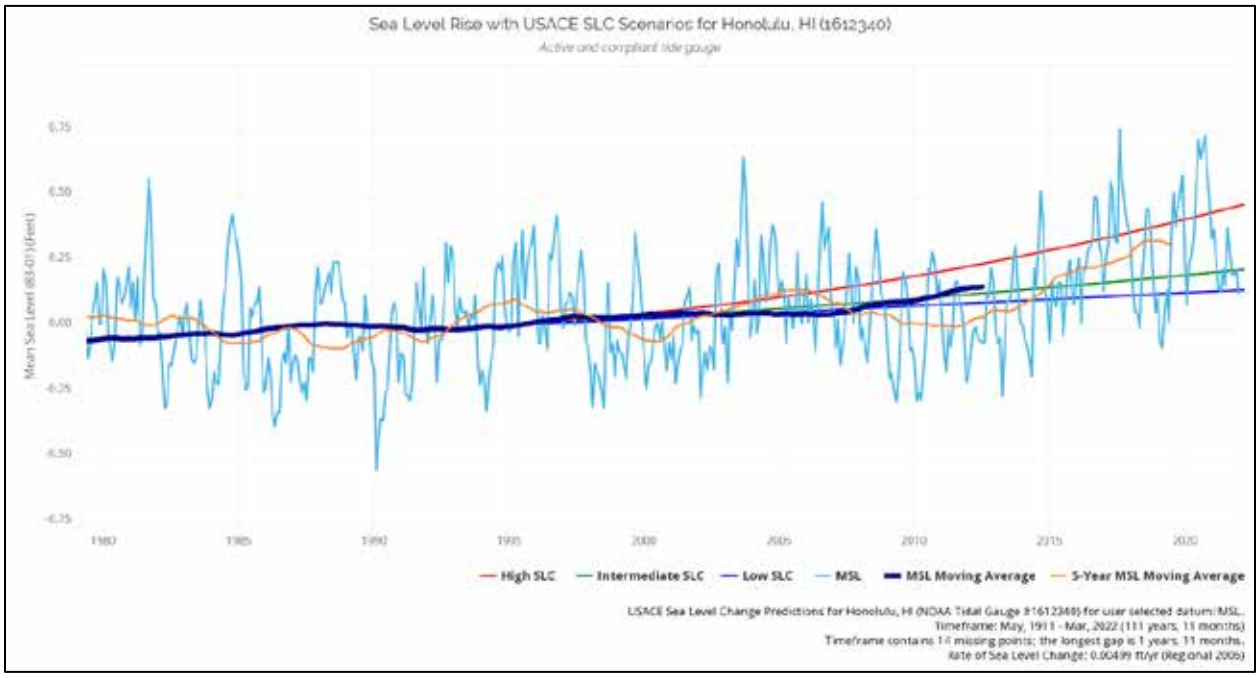

Figure 3-27: Historic Relative Sea Level Change 1980-2022 (US Army Corps of Engineers, n.d.)

3.5.3.2. Interannual Variability (IAV)

In addition to the SLC trends, the interannual variation of water surface elevations (WSEL) is "caused by irregular fluctuations in coastal ocean temperatures, salinities, winds, atmospheric pressures, and ocean currents. The interannual variation for many Pacific stations is closely related to the El Niño Southern Oscillation (ENSO)," (NOAA, 2022) the climate phenomenon in the Pacific Ocean evidenced by alternating periods of ocean warming and high air pressure in the western Pacific (El Niño) and cooler sea temperatures accompanied by lower air pressure in the western Pacific (La Niña) (L'Heureux, 2014). For the Honolulu gage, the IAV has been determined to be as much as 0.15 meters (0.49 feet). See Figure 3-24. The drivers for

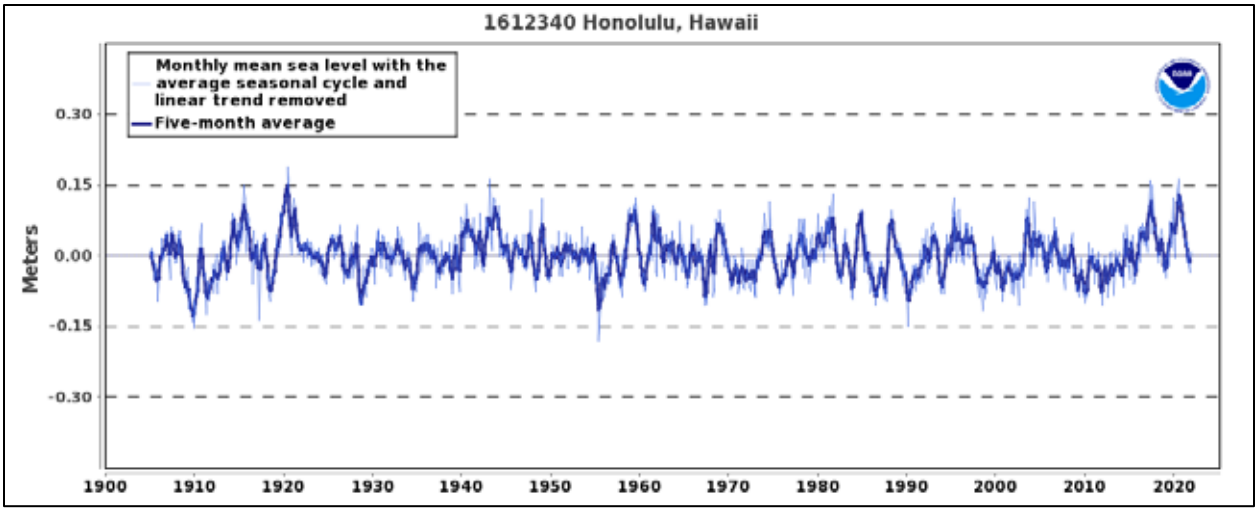

Figure 3-28: Interannual Variation of Monthly Mean Sea Level and the 5-Month Running Average at the Honolulu Gage (NOAA, 2022)

interannual variation are independent from the other factors that contribute to still water level trends (gravitational oscillation, storm surge, etc.), indicating that the average season cycle and linear sea level trends are not included. Therefore, IAV must be added to the overall estimation of future SLC and will be reflected within the downstream boundary conditions assumptions.

3.5.3.3. Selected Future Sea Level

Based upon the discussion above, it is concluded that definition of the future sea levels for the purposes of modeling the fluvial runoff boundary conditions will be best defined by the 99% AEP extreme water level that has been adjusted to include the anticipated SLC according to the Intermediate SLC curve and include the potential impacts of IAV. A summary of the computed values for the project economic life (2080) and 100-year adaptation horizon (2130) is shown in Table 3-6 and shown in Figure 3-25. For comparison purposes only, the 99% AEP EWL was added to the High Curve and included in this table.

It is noted that the linear combination of the various water level components introduces some uncertainty as the complex interaction of these components is unknown and could potentially be non-linear. Further research is warranted to better define the interactions and influences of each individual component in SLC.

Table 3-7: Computed SLC estimates (feet, LMSL 1992)

Year	USACE Low	USACE Intermediate	USACE High	USACE Int + EWL (99% AEP)	USACE High + EWL (99% AEP)	USACE Int + EWL (99% AEP) + IAV

3.5.4. Sensitivity Analysis of Tidal Influence

A sensitivity analysis of the downstream boundary conditions demonstrates the tidal influence was run on the calibrated HEC-RAS hydraulic model of the Ala Wai Watershed to determine the present and future “without project” WSEL for multiple scenarios, in compliance with USACE policy.

The following sensitivity analysis was completed using the NOAA gage at Honolulu Harbor. Three still water level elevations were used for the sensitivity analysis: the Mean Higher-High Water (MHHW), the 99% AEP EWL (1-year), and the 50% AEP (2-year) EWL, with a focus on the 99% and 50% AEP extreme water levels because of the results of the tidal-fluvial analysis discussed in Section 3.5.2. From the sea level trends assessment in Section 3.5.3, the intermediate sea level rise (SLR) curve was the focus for the sensitivity analysis of the extreme water levels, but the low and high sea level rise curves were also compared for the 2080 FWOP 99% AEP EWL. A full table of the model runs completed for the sensitivity analysis is shown in Table 3-7.

Table 3-8: Sensitivity Analysis Model Runs

	Still Water Level Scenario	Downstream Boundary Stage (ft LMSL 1992)	Runoff AEP
2030 (Intermediate Curve)	MHHW + IAV + SLR	1.90	50%
	MHHW + IAV + SLR	1.90	10%
	99% AEP EWL + IAV + SLR	2.43	50%
	99% AEP EWL + IAV + SLR	2.43	10%
	99% AEP EWL + IAV + SLR	2.43	5%
	50% AEP EWL + IAV + SLR	2.79	50%
	50% AEP EWL + IAV + SLR	2.79	10%
2080 (Intermediate Curve)	MHHW + IAV + SLR	2.69	50%
	MHHW + IAV + SLR	2.69	10%
	99% AEP EWL + IAV + SLR	3.22	50%
	99% AEP EWL + IAV + SLR	3.22	10%
	99% AEP EWL + IAV + SLR	3.22	5%
	50% AEP EWL + IAV + SLR	3.58	50%
	50% AEP EWL + IAV + SLR	3.58	10%
2080 (High & Low Curves)	99% AEP EWL + IAV + Low SLR	2.53	10%
	99% AEP EWL + IAV + High SLR	5.41	10%
2130 (Intermediate Curve)	99% AEP EWL + IAV + SLR	4.46	50%
	99% AEP EWL + IAV + SLR	4.46	10%
	99% AEP EWL + IAV + SLR	4.46	5%

The MHHW, the 99% AEP (1-year), and the 50% AEP (2-year) EWL elevations, including interannual variability and the 2080 FWOP intermediate sea level, were modeled for the 50% AEP (2 year) and 10% AEP (10 year) fluvial flood events. See Figure 3-23 for the scenarios on the Ala Wai Canal lower reach and the Makiki Stream for the 50% AEP (2 year) fluvial flood and Figure 3-24 for the scenarios on the Makiki Stream for the 10% (10 year) fluvial flood. See

Figure 3-25 for the scenarios on the Ala Wai Canal lower and middle reaches and the Manoa-Palolo Canal for the 50% AEP (2 year) fluvial flood, and see Figure 3-26 for the scenarios on the Manoa-Palolo Canal for the 10% AEP (10 year) fluvial flood.

Based on the model results in Figure 3-23-Figure 3-26, the tidal influence does not go upstream of the Phillip Street Bridge on the Makiki Stream or the Date Street Bridge on the Manoa-Palolo Canal. Figure 3-27 shows the inundation mapping for the 10% AEP (10 year) fluvial flood with the MHHW, 99% AEP, and 50% AEP EWLs, including IAV and the intermediate sea level rise curve. These inundation boundaries for the 10% AEP fluvial flood and downstream boundaries correspond to the same profiles shown in Figure 3-24 and Figure 3-26. Figure 3-28 is a close-up of Figure 3-27 showing just the area of tidal influence.

Increases in WSEs are expected due to the sea level rise in the tidal area of study at the downstream boundary condition. The increase in still water level elevations causes an increase in flooding for future without project conditions (FWOP) in the tidal area. The intermediate sea level rise curves show an increase of 0.79 feet over the 50-year project life (2030 to 2080), which would impact the Ala Wai Canal area of the project. While the sea level trend analysis showed that the intermediate curve would be appropriate for the future without project run scenarios, a sensitivity analysis was performed to compare all three SLR curves in the study area. The 99% AEP EWL with interannual variability was analyzed with varying sea level rise curves (low, intermediate, and high) for the 10% AEP fluvial flood event for the FWOP 2080 scenarios. See Figure 3-29 for the Ala Wai Canal lower reach and the Makiki Stream and Figure 3-30 for the Ala Wai Canal lower and middle reach and the Manoa-Palolo Canal. Based on the model results in Figure 3-29 and Figure 3-30, the sensitivity between sea level rise curves is negligible as far down as Fern Street on the Makiki Stream and does not go upstream of the Date Street Bridge on the Manoa-Palolo Canal.

The 99% AEP (1 year) EWL, compounded with interannual variability and the intermediate sea level rise curves, for the existing without project 2030, FWOP 2080, and FWOP 2130 conditions were analyzed with 50% AEP (2 year), 10% AEP (10 year), and 5% (20 year) fluvial storm event. See Figure 3-31 for the Ala Wai Canal lower reach and the Makiki Stream and Figure 3-32 for the Ala Wai Canal lower and middle reach and the Manoa-Palolo Canal. These model runs show that the impact of sea level rise using the intermediate SLR curve for the without-project conditions from the base year of 2030 to the FWOP 2080 and FWOP 2130 lifespan all have about the same tidal zone of influence for the 50% AEP (2 year), 10% AEP (10 year), and 5% AEP (20 year) fluvial floods. These results are largely in part due to the Phillip Street and Date Street bridge constrictions as well as the steep channel slope on the mauka side (mountain side) of the canal. Tidal flooding within the downstream study area becomes less influential as the inland storm events increase in magnitude. Since the tidal impact does not propagate upstream of Phillip Street on the Makiki Stream or Date Street on the Manoa-Palolo Canal, it was determined that sensitivity runs on larger fluvial flood events was not required.

From the sensitivity analysis, it has been determined that the tidally influenced flooding does not go beyond the Phillip Street Bridge on the Makiki Stream and the Date Street on the Manoa-Palolo Canal for future unimproved conditions due to the steep bed slopes and topographic characteristics of the overbanks.

In support of Climate Preparedness and Resilience analyses (see Also Appendix H), to fully understand extreme possible scenarios and considering the Future With Project Conditions, a comparison was made including for downstream boundary elevations of 99% AEP EWL and 1% EWL equal to 5.41 feet and 6.3 feet respectively (including interannual variability and referencing the High Sea Level Rise Curve). Elevations were compared near the downstream end of the canal upstream of the Makiki Canal mouth, as shown in Figure 3-40 and further defined in Table 3-9. A comparison of the inundation extents for the 99% EWL and 1% EWL events described above combined with the 5% fluvial storm event is shown in Figure 3-41 and Figure 3-42.

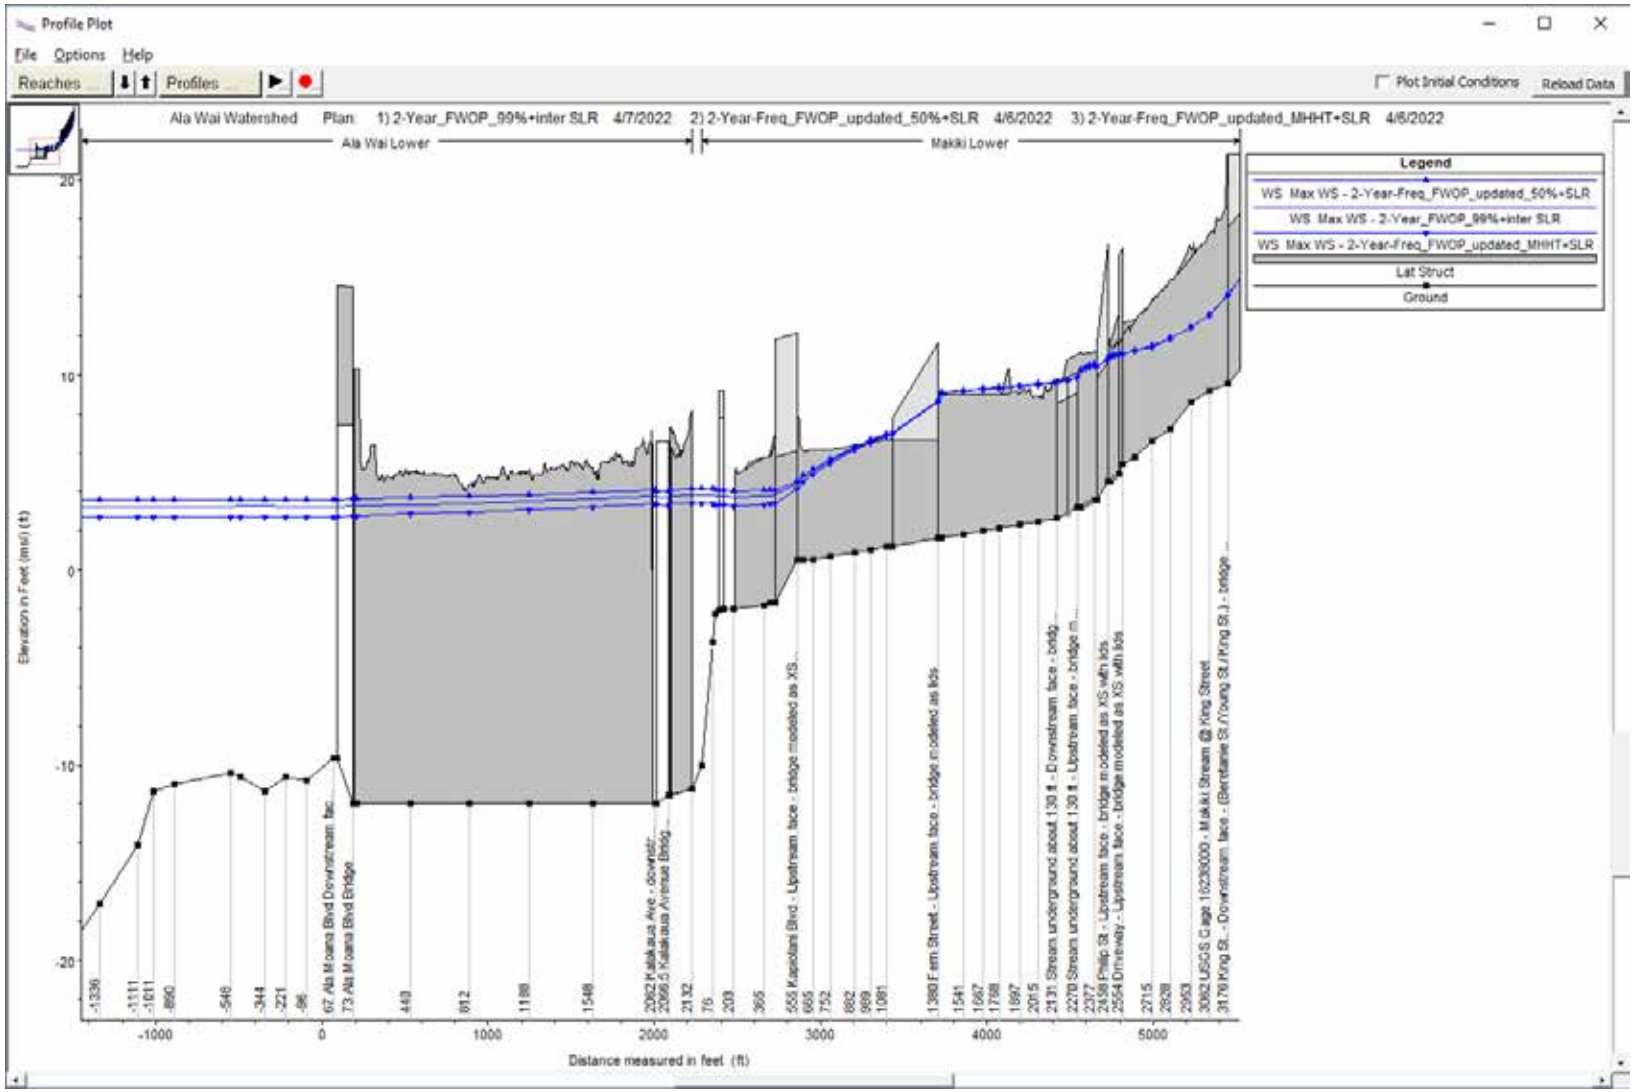

Figure 3-30: FWOP 2080 condition with 50% AEP (2 year) fluvial flooding with the MHHW, 99% AEP (1 year) and 50% AEP (2 year) EWL with IAV and the Intermediate Sea Level Rise Curves on the Ala Wai Canal Lower Reach and the Makiki Stream.

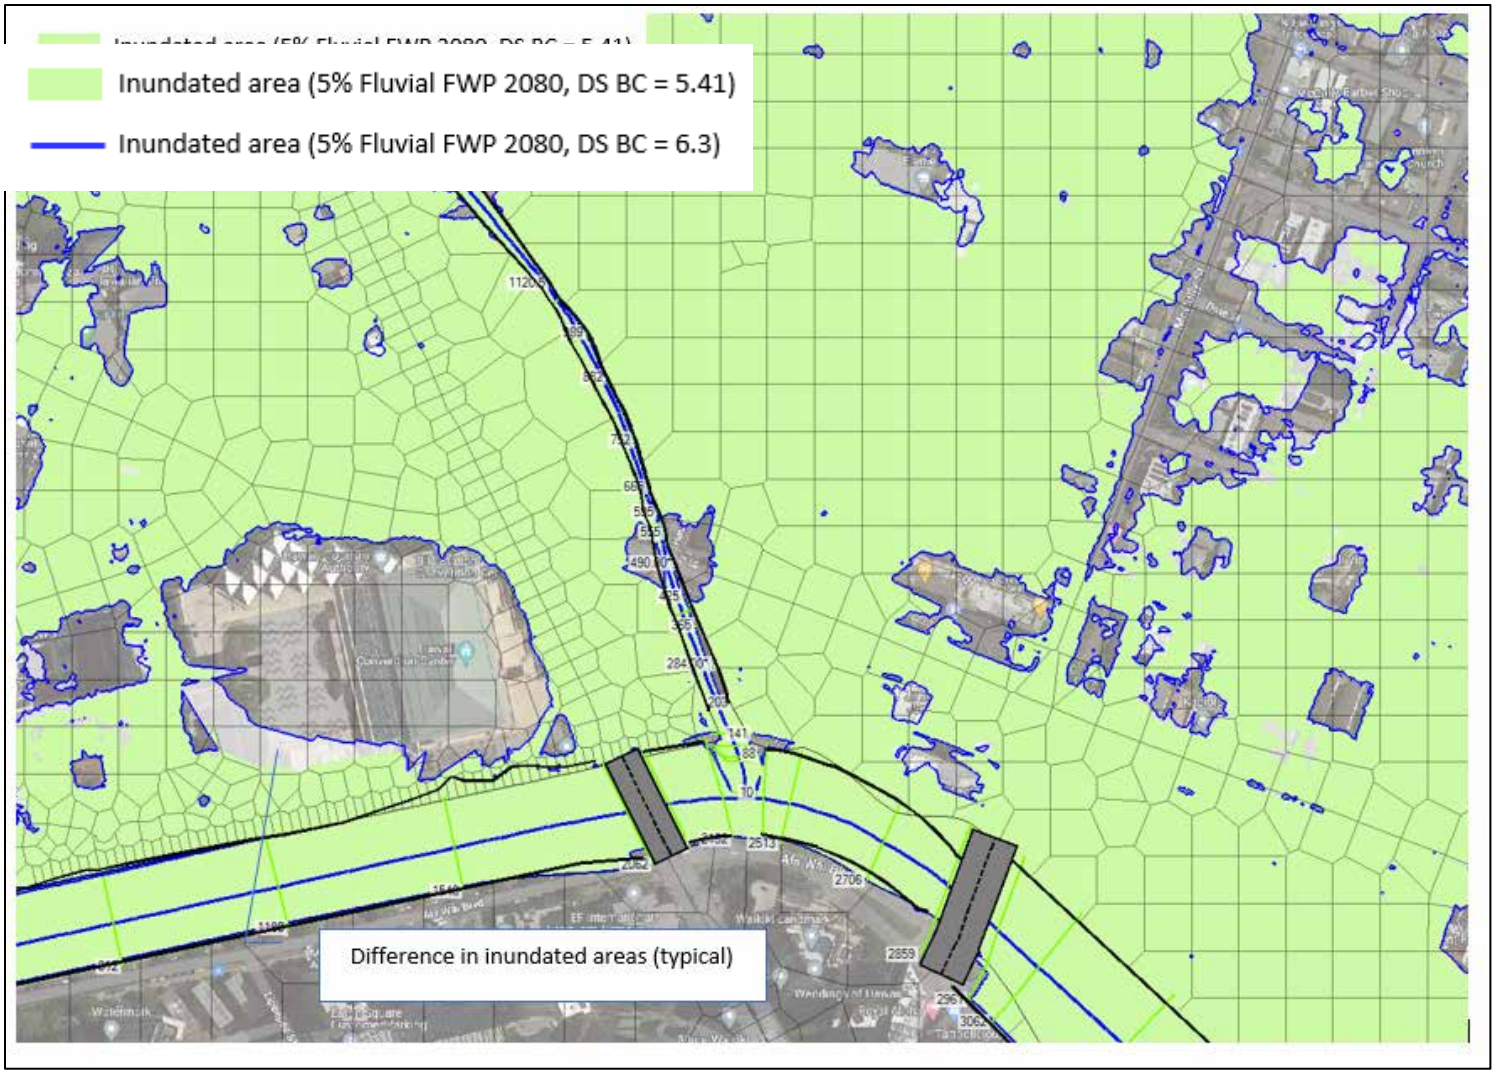

Figure 3-42 Inset view from Figure 3-41showing typical differences in inundation extents for 5% AEP fluvial storm event for FWP Conditions with of 99% AEP EWL and 1% EWL (including interannual variability and referencing the High Sea Level Rise Curve).

3.5.5. Coincident Peak Sensitivity of the Coastal Flood Elevations

A sensitivity analysis of the water surface profile for the 10% AEP riverine flood was conducted for a range of downstream coastal extreme water level elevations from the NOAA extreme elevations for the 99% AEP to the 10% AEP to follow the simplified method described in Figure 11-1 of EM 1110-2-1415 (See Figure 3-43). As the true riverine profiles lie within the range highlighted in yellow in Figure 3-40 below, which is that figure from the EM, this is a critical analysis (Blodgett, 2023).

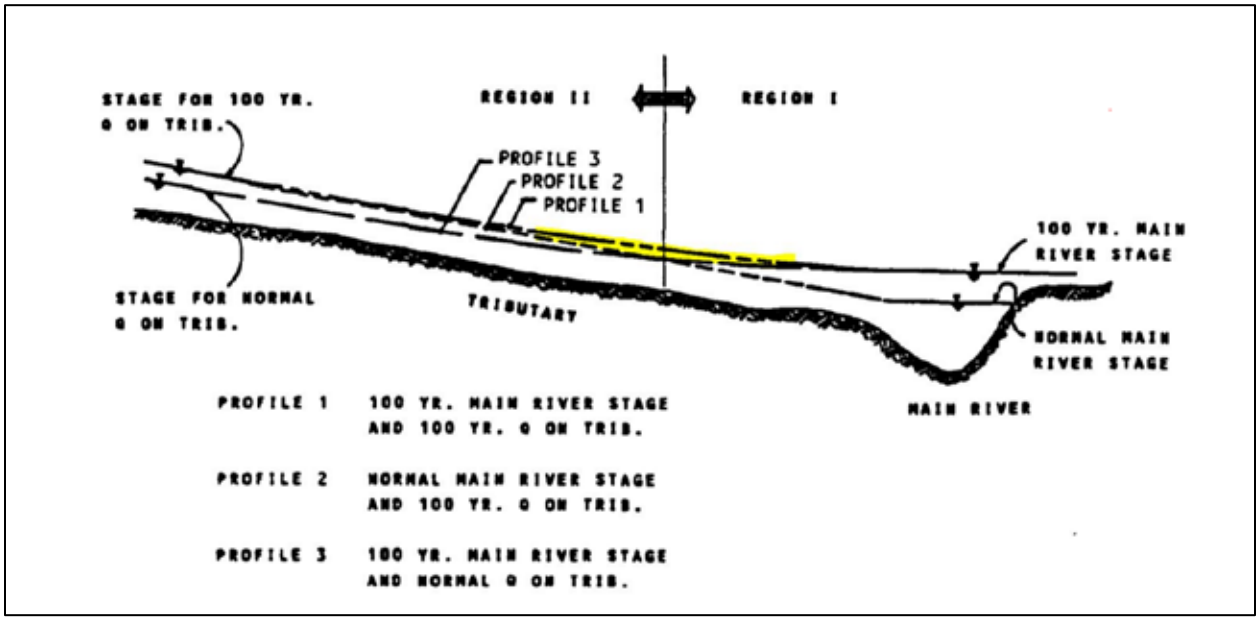

Figure 3-43: Coincident Peak Figure from EM 1110-2-1415

The sensitivity analysis was accomplished by extracting the downstream reach from the HEC-RAS 2D hydraulic model. To evaluate the 10% AEP profile, the model was executed using steady state assumptions for the range of water surface profile scenarios described in Figure Figure 3-44. The true annual exceedance probability profile lies within the range highlighted in yellow (Blodgett, 2023).

For the purposes of this analysis, the peak 10% flow was a rough estimate obtained from the Validation Study RAS 2D model. To test how a profile might be impacted under a higher floodwall condition in the Ala Wai Canal reach, the 10% AEP flow was extracted from a cross section in an upstream reach of the PED hydraulic model that was not significantly impacted by upstream channel overtopping. The results of the analysis are presented in the graphic below. The results indicate that a higher 10% AEP ocean stage was only about 1 foot higher than the 99% AEP ocean stage and did not extend very far upstream due to the steep hydraulic grade line of the riverine profile (Blodgett, 2023).

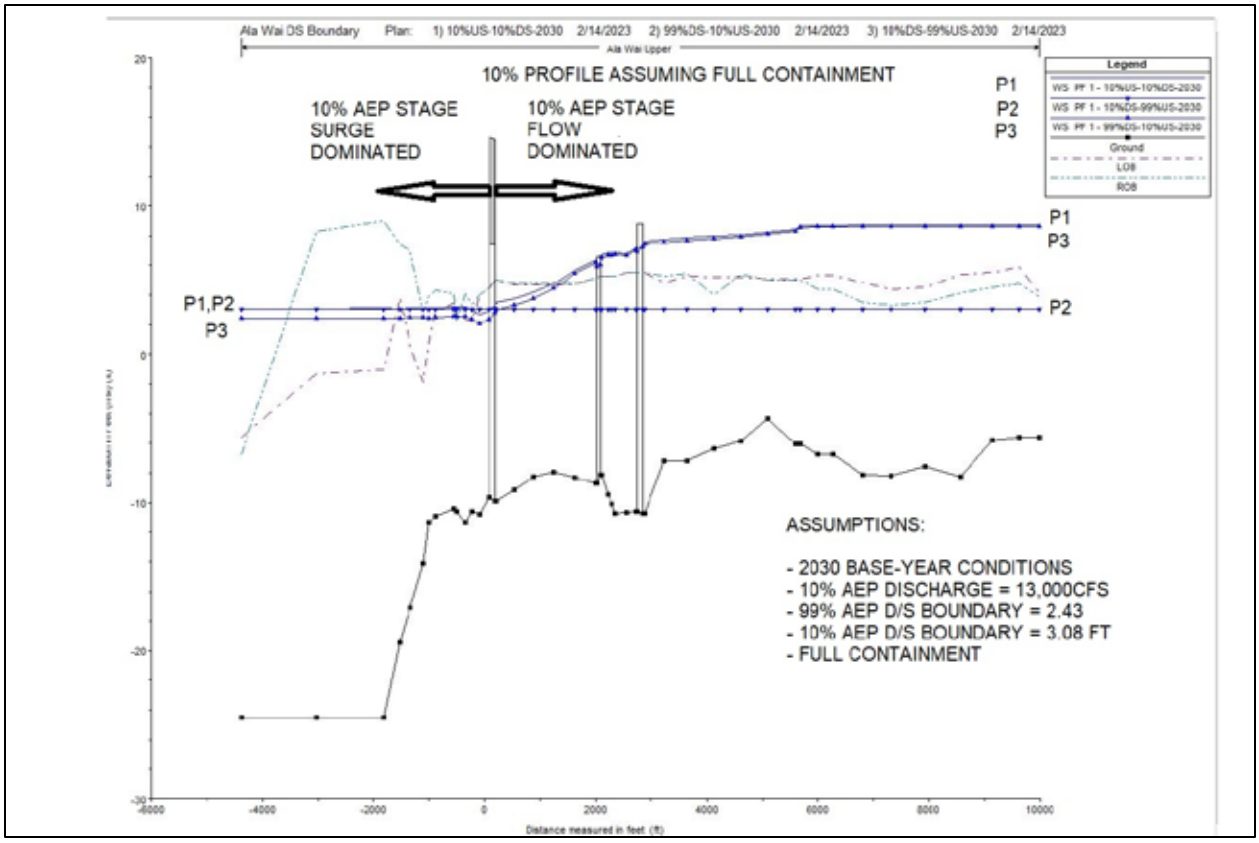

Figure 3-44: Coincident Peak on Ala Wai Canal

It was concluded that the current assumption of using the 99% AEP profile would not significantly impact the assessment of costs or benefits of the plans and was highly unlikely to impact plan selection. It was recommended that the higher downstream ocean profiles be considered during more detailed design and analysis after the TSP. it was also noted that the possibility of high velocities and potential scour in this reach could exist based on the steep riverine profiles observed in the analysis. Velocities would be even higher under a low tide condition at the downstream boundary condition (Blodgett, 2023).

3.5.6. Conclusion

The appropriate downstream boundary condition for this project was determined by assessing the tidal-fluvial relationship, historic sea level trends, tidal phenomena, and the sensitivity of the study area to varying tidal conditions. It was determined that there was not a strong relationship between fluvial events and concurrent tidal events. Therefore, joint-probability and coincident frequency analyses were not necessary, and a simplified approach to defining the base tidal elevation was adopted. As such, the majority of high runoff fluvial events occur when tidal elevations are less than the 99% AEP EWL; therefore, the 99% AEP EWL was determined as an appropriately conservative base tidal elevation to use as the downstream model boundary condition. The future sea level rate of rise was determined by analyzing historic tide levels and historic trends. As such, the Intermediate SLC curve was chosen as the most representative

rate of rise for the study area. Additionally, the future sea level includes interannual variability, since extreme water levels and seasonal tidal variation are independent of IAV. The final downstream boundary condition was determined to be the 99% AEP EWL, including the intermediate SLR and IAV, for a project economic life (2080) still water level elevation of 3.22 ft-LMSL (1983-2001 tidal epoch) and a 100-year adaptation horizon (2130) still water level elevation of 4.46 ft-LMSL (1983-2001 tidal epoch).

Per USACE policy and guidance, a sensitivity analysis was completed to validate the above assumptions. Modeling of multiple combinations of downstream boundary conditions shows that upstream water surface elevations are not sensitive to the downstream boundary condition. The tidal influence does not encroach more than 0.5 miles from the canal upstream of the Makiki and Manoa-Palolo tributaries where the streams are constricted by bridges and begin to steepen on the mauka side of the canal. It was also determined that the still water level elevation is not influential for streamflow greater than the 5% AEP event.

The downstream boundary condition of the 99% AEP EWL, including the intermediate SLR and IAV, is the most appropriate assumption when evaluating the effects of various mitigation measures and scenarios for this project.

3.6. Existing Conditions and Future Without Project Conditions Modeling Errors

Volume errors and maximum water surface elevations were evaluated, and multiple iterations of every flood profile was run with various time steps, 2D time slices, and number of allowed iterations between 1D and 2D were run to minimize the errors. All of the volume errors were less than 3% with the SWE-EM full momentum stricter equations for 2D flow. The vast majority of the volume errors were due to less flow out of the 2D perimeters than flow in. This could be due to the total simulation time run and some flow not fully leaving the 2D areas before the end of the simulations. The models were run for the full length of the input hydrographs, so if the models need to run for a longer time period, then the input hydrographs would need to be extended. This was not done due to the already very long model run times. The peak flood flows fully moved through the system, even if all water did not dissipate yet. See Table 3-10 below for the volume errors and max water surface elevation errors.

Table 3-10: Existing and Future Without Project Modeling Volume Errors and Maximum Water Surface Elevation Errors

	Existing Conditions (Base Year 2030)			Future Without Project Conditions (Year 2080)		
AEP	Overall volume accounting error (in Acre Feet)	Overall volume accounting error (as percentage)	max xsec wsel error (in feet)	Overall volume accounting error (in Acre Feet)	Overall volume accounting error (as percentage)	max xsec wsel error (in feet)

4. Project Measures

4.1. Overview

The objective of the Ala Wai Canal Flood Risk Management (FRM) Project is to reduce riverine flood risks in the Ala Wai Watershed. Flooding was analyzed for 8 frequency events: the 50%, 20%, 10%, 5%, 2%, 1%, 0.5%, and 0.2% annual exceedance probability (AEP) flood events. This corresponds to the 2-year, 5-year, 10-year, 20-year, 50-year, 100-year, 200-year, and 500-year return intervals. A 24-hour rainfall event was assumed for each frequency scenario. These storm events were initially used to analyze flooding associated with existing conditions and later used to assess potential flood reduction measures. Specifically for the 1% AEP storm event, a previous study estimated that approximately 1,358 acres within the Ala Wai Watershed was affected, including over 3,200 properties at an estimated $720 million in structural damages for 2021 price levels.

The 2017 FEIS recommended an interconnected system of debris and detention structures and a flood barrier system intended to slow down floodwater as it flows towards the ocean and enhance the capacity of the Ala Wai Canal and Ala Wai Golf Course to retain peak volume of flash floods through a combination of berms, levees, and walls. Within the system, upper watershed debris and detention basins were designed to detain short duration, high intensity rainfalls in the upper watersheds at the source and to reduce and offset peak discharges to more manageable flows into the Ala Wai Canal at the base of the watershed. The lower watershed multi-purpose detention basins, floodwalls, and associated pump stations were designed to increase overall storage capacity at and around the Ala Wai Canal.

The Validation Study updated the hydrologic and hydraulic modeling, and evaluated many of the 2017 FEIS measures, along with some new and revised measures that utilized the same general flood risk reduction concepts.

Many of the concepts from the 2017 FEIS and the 2021 Validation Study were formulated into a robust list of initial flood reduction measures spread widely throughout the basin. In total, 224 measures were identified across the basin. These measures were then analyzed and screened down to a final list to be further evaluated for later use in the final alternatives. This screening effort consisted of applying engineering judgement to the effectiveness and viability of the initial measures and allowed for a final list of measures to be selected for further evaluation. The final measures are shown in Table 4-6.

4.2. Screening of Hydrologic Measures

The purpose of this investigation is to conceptually consider other proposed measures to reduce runoff from the watershed in order to mitigate increased flooding downstream. Three primary concerns were identified as contributors to increased runoff:

1. compaction of soils and destruction of vegetation by wild ungulates (hooved mammals);
2. changes to runoff and erosion characteristics by invasive plant species; and
3. increases to impervious surface area due to human development.

This discussion summarizes the conceptual, screening level evaluation of suggested measures to mitigate these concerns, with the targeted result of increasing the capacity of the soil and vegetation to absorb rainfall and decrease runoff. For the purposes of expediency as well as discussion, extreme values may be assumed based upon engineering judgement to determine whether the measure could potentially provide benefit and merit further study. Figure 4-1 shows the Ala Wai watershed, sub-basins for the hydrologic model HEC-HMS, and aerial photography. The aerial image clearly indicates the developed areas in contrast to the wooded vegetated areas.

4.2.1. Restoration of Upper Watershed Vegetation (Ungulate Control)

Populations of feral animals, particularly hooved mammals, can have significant impacts on vegetated areas. Much of the vegetated areas of Hawaii evolved without these animals prior to them being introduced by settlers (Hawai'i Conservation Alliance, 2001) "…[H]oofed animals like feral goats and pigs … compact soils, reducing their ability to absorb water. … Studies have shown approximately 20-70% of the ground in a Hawaiian rainforest converted to bare soil due to pig digging. Other grazers, such as feral cattle, deer, and goats, can completely denude a forest." (Yuen, 2021) Loss of vegetative cover reduces interception of rainfall and therefore increases runoff from storm events.

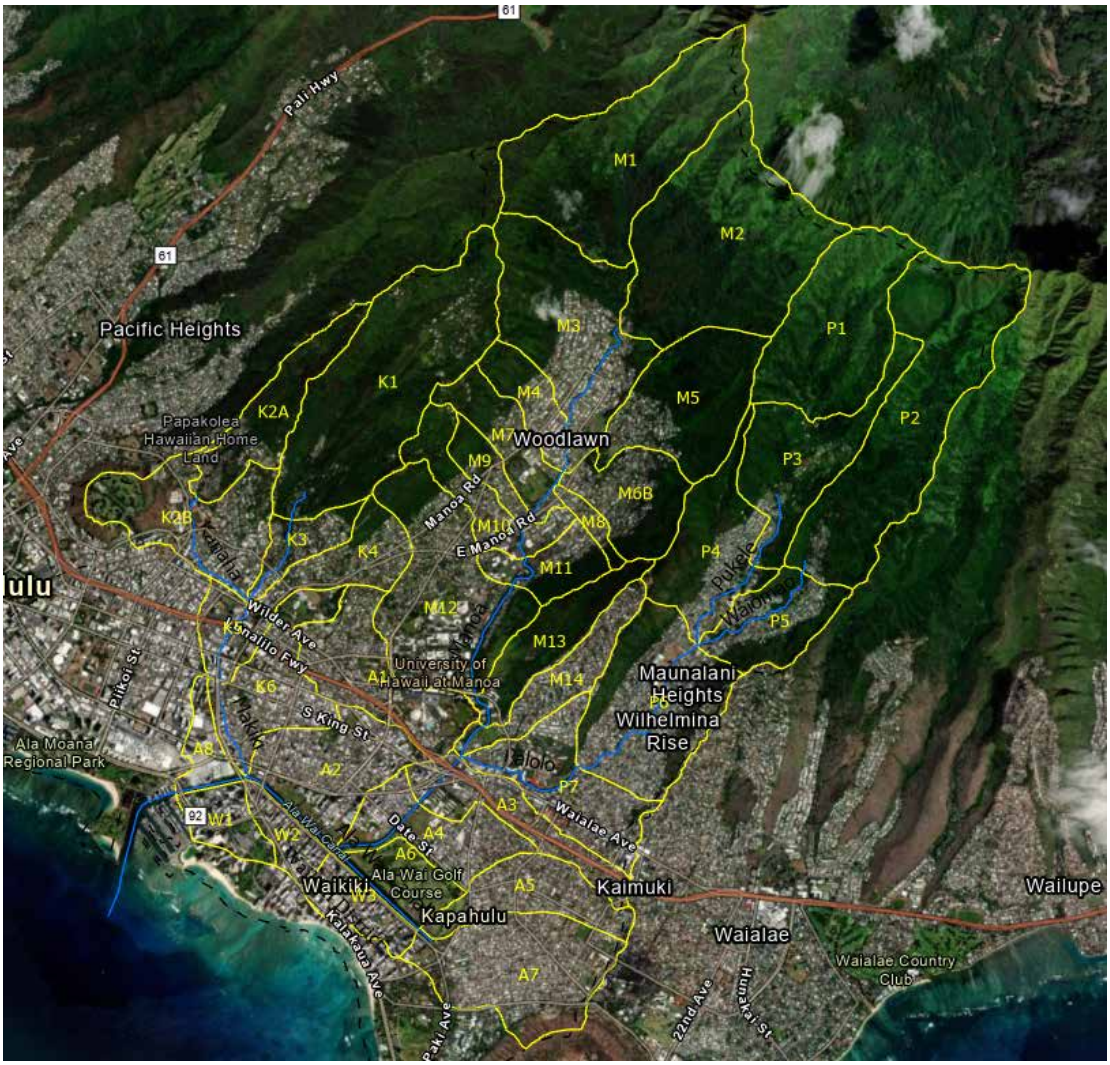

Figure 4-1 Ala Wai Watershed

The proposed mitigation in the upper watershed is to confine ungulate movements to certain areas with the installation of fences. While ungulate control efforts are planned in the upper most reaches of the watershed (indicated as gray lines in Figure 4-2 below) where the highest amounts of precipitation fall on steepest slopes, and therefore most prone to flooding (Roth, 2022), it is understood from the above reference that the problem is pervasive throughout the forested areas of the watershed. For the purposes of this examination, it is assumed that implementation of control efforts of this or similar fashion could eliminate the substantial damage caused by animals throughout the basin. The primary means of representing a change in the vegetation and compaction of soils caused is through the relative change in the Curve Number (CN), a variable utilized in the loss model created by used U.S. Department of Agriculture (USDA) Natural Resource Conservation Service (NRCS, formerly the Soil Conservation Service or SCS), and used in the HEC-HMS model of the watershed. The

assumptions of CN changes are applied to all sub-watersheds that are wooded as a conservative estimate.

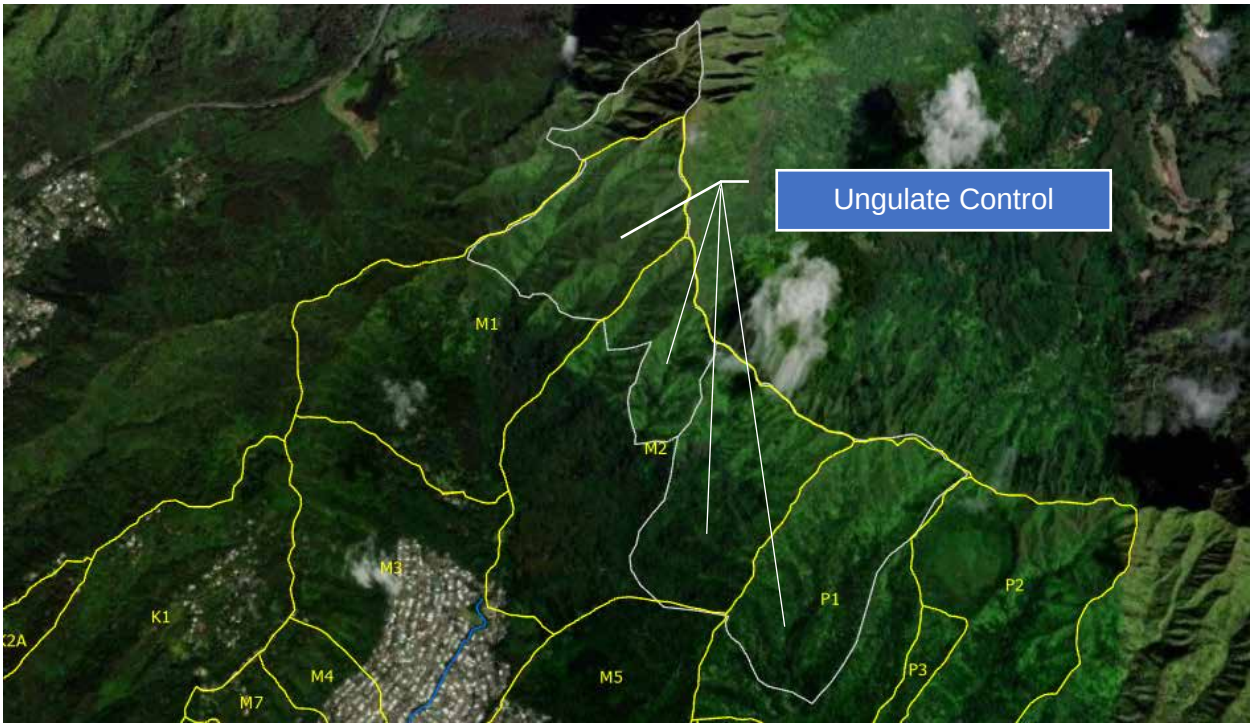

Figure 4-2 Locally planned areas for ungulate controls

The relevant parameter within the HEC-HMS model for analyzing impact of reducing watershed damage by hooved animals is the curve number (CN), which is an index of the ground surface's effectiveness at intercepting rainfall. The CN value for a sub-basin considers the average type of land use (e.g., impervious area, pasture, wooded areas, etc.,) and the relative ability of the soil types in the sub-basin to allow infiltration, as indicated by the soil type's Hydrologic Soil Group classification. The original analysis that developed the original flood hydrographs in HEC-WAT assumed CN values per NRCS TR-55 guidance for wooded areas, particularly Land uses of "Evergreen Forest" and "Scrub/Shrub" ranging from "Good" to "Fair" condition and weighted based upon the Hydrologic Soil Group classification of soils within each sub-watershed (see Figure 4-3).

Table 2-2c Runoff curve numbers for other agricultural lands 1/

Cover description		Curve numbers for hydrologic soil group			
Cover type	Hydrologic condition	A	B	C	D
…					
Woods. 6/	Poor	45	66	77	83
	Fair	36	60	73	79
	Good	30 4/	55	70	77

Figure 4-3 Excerpt from NRCS TR-55 CN Tables

Per the NRCS WebSoilSurvey online tools, soils in the undeveloped regions of the watershed are largely soil types A, B and C (Figure 4-4). For the purposes of this conceptual analysis, the relative impact of eliminating the damage by ungulates and recovery of vegetation was approximated by decreasing the CN values for all soil types for Evergreen Forest and Scrub/Shrub by a value of 10, selected as an approximate average of the difference in CN values for "Poor" to "Good" condition of the wooded areas in the watershed. When combined with the other land uses in each subbasin, weighted by the area of each land use type, this lowered the composite CN values for the sub-areas in Table 4-1 by a range of 11-15.

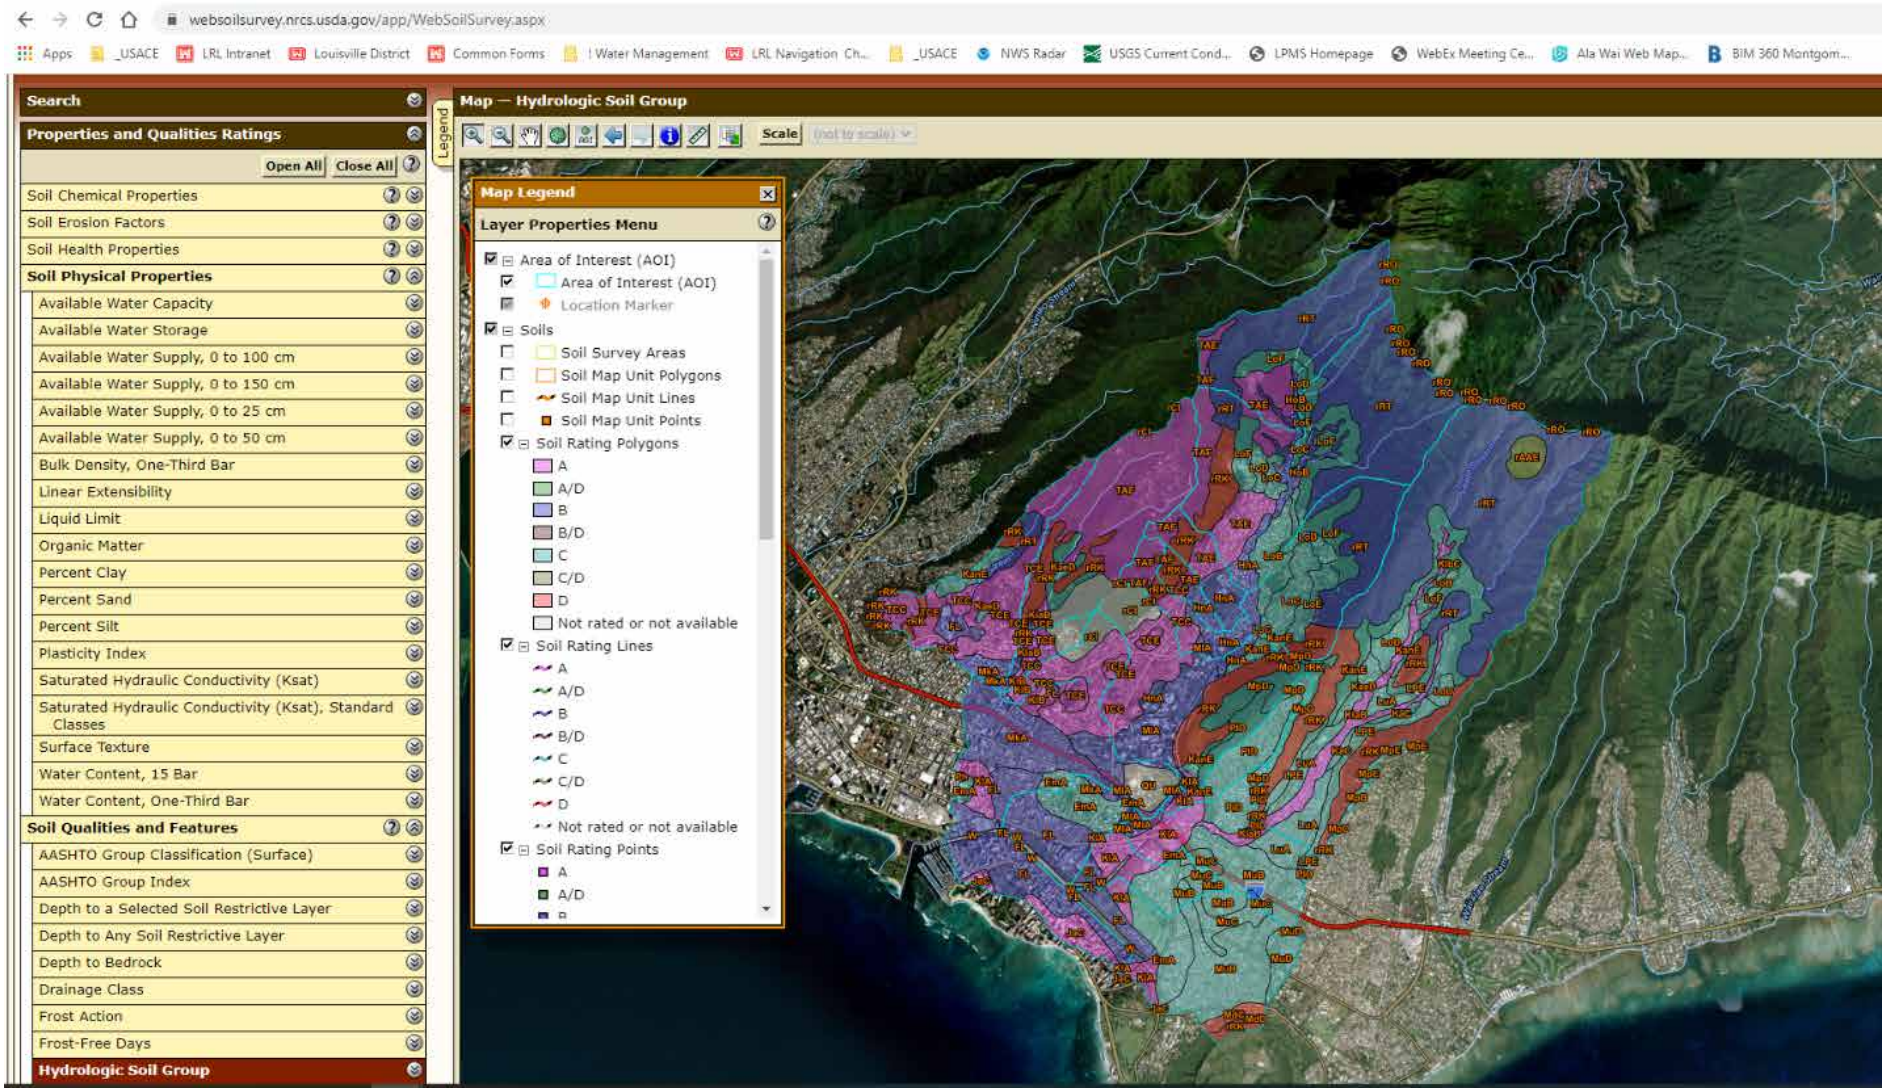

Figure 4-4 Hydrologic Soil Groups

Table 4-1 Original vs. Adjusted Curve Numbers due to Ungulate Control

Subbasin	Lower SCS Loss Coefficient (CN)	Upper SCS Loss Coefficient (CN)	Original SCS Loss Coefficient (CN)	Initial Abstraction (in.)	New CN

4.2.2. Restoration of Watershed through Invasive Vegetation Control

4.2.2.1. Impacts

Per information shared by the Hawaii Department of Fish and Wildlife (DOFAW) (Roth, 2022), new research is showing that when forests are protected from invasive vegetation and ungulates, they are 25% faster at infiltration (Roth, 2022). “Native forests are naturally very effective at capturing and absorbing rainwater, which reduces sedimentation and outflow” (Roth, 2022). In the damaged barren areas that are the result of the invasive vegetation or ungulate traffic, infiltration is observed to be 15 times slower, which can magnify the runoff from storm events. Additionally, the natural vegetative debris from a forest of native plants are substantially less than that of an albizia forest. When species like miconia, albizia, and angiopteris evecta (“mule’s foot fern”) dominate the canopy, the forest's understory is reduced to bare earth. Removal of invasive vegetation allows for potential recovery for all levels from groundcover to canopy (Roth, 2022).

“Miconia is a species known to promote erosion and higher rates of runoff due to its shallow roots and large leaves “ (Roth, 2022). Reduced light infiltration inhibits the growth of understory vegetation, ultimately reducing the floor to bare earth (see Figure 4-5). This increases erosion and runoff especially during intense rain events. This is compounded by Miconia’s large leaves as the raindrops are consolidating into much larger drops than the direct rainfall, accelerating erosion on the already bare ground (Roth, 2022).

Figure 4-5 Denuded forest floor below miconia (Nelson, 2020)

Mule's foot fern is a large ground-rooting ornamental fern that forms dense monotypic stands that completely displace understory species, also turning the forest floor to bare earth. Mule's foot fern readily infiltrated stream banks, contributing to increased runoff and erosion, causing increased sediment buildup in channels (Roth, 2022).

4.2.2.2. Extents

The lower reaches of Manoa and Palolo watersheds and nearly all of the Makiki watershed are dominated by non-native and invasive plants, with minimal remaining native cover. "The lower reaches of the back and Western sides of Manoa valley have the heaviest infestation of albizia and other invasive species" such as mule's foot fern and miconia (Roth, 2022). For miconia, the heaviest infestations are in the lower elevation forest (below 1,000 feet in elevation) mostly along streams from Nuuanu to the eastern side of Manoa Valley. Some of the heaviest infestations for miconia have been found in the Nuuanu/Makiki areas that contain the Makiki Trail System over to the Aihualama and Manoa Falls area, as well as in the Puu Pia area and behind Lyon Arboretum (Roth, 2022). Figure 6 and Figure 39 represent partial extents of miconia and albizia as developed from GIS data provided by University of Hawaii personnel; it is noted by the source particularly that the albizia extents are not comprehensive of the entire watershed, but rather focused on areas of ongoing removal projects.

Figure 4-6 Miconia Extent (2020) (Dube, 2021)

Figure 4-7 Albizia Extents (Davis, 2021)

4.2.2.3. Evaluation

Based upon available data above including Figure 6 and Figure 39 and potential for proliferation, the extent of invasive vegetation as a percentage of vegetative land cover is conservatively estimated as shown in Table 4-2.

Table 4-2 Undeveloped Land Cover

Sub-Basin	Percent of Undeveloped Vegetative land cover		
	as Miconia	as Albizia and Mules Foot Fern	Total for Potential Improvement
M1	33%	20%*	53%
M2	25%	50%	75%
M3	50%	20%*	70%
M4		20%*	20%
M5	10%	20%	30%
M7		40%*	40%
M9		40%*	40%
M10		40%*	40%
M12		40%*	40%
K1	10%		10%

Per Figure 4-7, the extent of Albizia in the upper Palolo sub-basin is limited, so that it is assumed that even if fully mitigated, the effect on the overall runoff characteristics of the sub-basins would be very small. As it is very high in the Palolo watershed, the impact of full mitigation to flows downstream should also be negligible. As stated in the literature, the impact of these invasive plants reduces or eliminates the undergrowth vegetation which significantly decreases the interception of precipitation and decreases the infiltration. The relevant hydrologic model parameters that represent these physical processes in the existing HEC-HMS model is the CN and the Initial Abstraction (Ia). The Initial Abstraction is defined as the initial fraction of the storm depth, after which surface excess becomes runoff, combining a number of variables related to interception, rainfall intensity, and physical absorption capabilities of the soil (Natural Resources Conservation Service). Guidance or research could not be located to quantify the effects of decreased infiltration in terms of Initial Abstraction or CN, therefore for the purposes of this preliminary investigation, judgment was used to estimate that Ia would increase by 1 inch of precipitation and CN would decrease by a value of 5. The change in CN was approximated to represent a single level change in Hydrologic Condition, (e.g., “Poor” to “Fair”, or “Fair” to “Good”) as indicated above in Figure 3. The increase in Ia of 1 inch was selected as a liberal improvement in the ability of the affected area to intercept and infiltrate before runoff would occur due to the reestablishment of understory vegetation, the roots of which tend to increase the soil porosity. The changes in the input values are summarized in Table 4-3.

Table 4-3 Model CN and Ia

Subbasin	Original SCS Loss Coefficient (CN)	Initial Abstraction (in.)	New CN	New Initial Abstraction (in.)
M1	67	0.52	62	1.5
M2	65	0.44	60	1.45
M3	72	0.52	67	1.5
M4	77	0.52	72	1.5
M5	65.2	0.52	60	1.5
M7	73	0.52	68	1.5
M10	79	0.52	74	1.5
M12	77	0.40	72	1.4
K1	43.7	1.0	38	2.0

4.2.3. Reduction in Impervious Surfaces

As discussed by the previous scenarios, the ability of the watershed soils to absorb initial rainfall directly relates to the amount of runoff from a watershed in channels and thus the potential for flooding for a particular storm. Urban development creates hard, impervious surfaces (e.g., compacted soils, paved roads and sidewalks, roofs) preventing rainfall infiltration into the soil surface, but also displaces the vegetation that normally intercepts rainfall; the vegetation has a much greater relative surface areas to intercept the rain. Over time, the resulting urban flooding that occurs due to the increased runoff has necessitated that metropolitan areas implement development restrictions limiting the amount of runoff from new construction through detention, but these designs are largely aimed at reducing the runoff from more frequent flood events. More recent programs look to increase the interception of rainfall, slow down how quickly the runoff gets to channels, and increase the amount of infiltration into the soil surface. This can occur through technologies and practices like use of vegetated “green” roofs, rain barrels or storage tanks, gravel or pervious pavements, rain gardens, removal of drainpipe connections to sewers and streams, or simply replacing hard surfaces like pavements with vegetated areas.

A high-level analysis was performed to quantify whether a large-scale program to reduce impervious area and/or improve infiltration rates would potentially change discharges.

In the more urbanized sub-basins in the watershed as represented in HEC-HMS, the Kinematic Wave model is used. The Kinematic Wave runoff model conceptually represents the sub-basin as two overland flow surfaces or “planes”, one plane representing areas that are essentially impervious with short lengths of flow, and a second plane representing pervious areas and having values representing higher infiltration capacity and resistance to flow (MacArthur & DeVries, 1993).

This method was applied to the sub-basins listed in Table 4-4, which are the most highly developed areas of the watershed. Table 4-4 shows the base model CN parameters and the expected range of CN defined in previous studies and used in HEC-WAT to develop the final frequency hydrographs representing existing conditions.

For the purposes of this analysis, an initial trial (Trial "RedImp") estimated that restoration measures would conservatively reduce the Plane 2 CN from the fully impervious assumption (CN = 98) and increase the Ia from 0.1 inch to be equivalent to the Plane 1 Lower CN and Ia previously assumed for the purposes of concept examination. The Plane 1 Lower CN is assumed to include some impervious surfaces that are not feasible to fully eliminate/mitigate or is the best CN that could be expected to be achieved based upon soil types in the sub-watershed. This analysis does not attempt to recalculate composite CN estimates for individual watersheds, assuming that the original hydrologic modeling reflected the respective mix of soils and land use to establish those values.

A second trial (Trial "RedImp2") emulated a change of 25% of the High Intensity Developed areas to Grassland by adjusting the CN computations for these same sub-basins. Looking at the relative results for the 1% event (Table 4-5), the reduction in peak discharge was observed to be minimal so this scenario was not evaluated further.

Table 4-4: Flow Plane SCS Loss Value Uncertainty Range

Subbasin	Plane 2 Base Curve Number	Plane 1 Base Curve Number	Plane 1 Base Initial Abstraction (IN)	Plane 1 Lower Curve Number	Plane 1 Upper Curve Number

Makiki at mouth	5,930	5,834
OUTLET	34,759	34,582

4.2.4. Interpretation / Application of Results to Study

The peak discharges as a result of the changes to the HEC-HMS model are tabulated in Addendum E for nine (9) frequency flood events. This table compares the model peak flows for existing conditions ("Ex Cond"), ungulate control ("Ungulate"), invasive vegetation mitigation ("InvVegMit"), and reduction of Impervious areas ("RedImp") scenarios based upon the model changes described above. As modeled, the plans to mitigate for invasive species of vegetation in the watershed show the greatest reduction potential in peak discharges of the three proposed measures. Given the steepness of the watershed and tendency for flood events to be flashy in nature, rising and falling over a very short period, the relatively small decreases in peak flows that are presented are an indication that the reductions in inundated areas will also be small. As indicated in Appendix A, the relative magnitude of the reductions in peak flows decrease with increasing magnitude (decreasing annual exceedance probability) of the storm events. A test was performed to validate the interpretation that the reduction in inundated areas would be small by comparing the 10% AEP storm inundation boundary for the future without-project (FWOP) conditions versus the inundation boundary resulting from the reduced flow for the Invasive Vegetation Mitigation plan in HEC-RAS. In Figure 4-8, the yellow areas were no longer inundated using the reduced flows for the Invasive Vegetation Mitigation during the 10% AEP

event. The largest concentrated area of improvement can be seen east of the Makiki stream at the H1/Lunalilo Freeway and the lower end of the Manoa University campus. In general, the changes in depths were small on the order of 0.5 foot, with the greatest changes in inundated area apparent where water surfaces didn't exceed the threshold for a pathway connecting to the isolated area.

It is noted that the three measures discussed above cannot be implemented in a short time; rather, to achieve reductions to the order of magnitude indicated here will require a sustained implementation program of these measures over the course of many years or even decades. For the initiatives to restore control the invasive vegetation and ungulates, it will take years for native vegetation and undergrowth to reestablish and restore the root systems to improve the soil infiltration capacity. It should also be noted that removal of invasive vegetation and its interception capability (although potentially small) may increase runoff in the short term until native vegetation is re-established. Changes to impervious areas will require a sustained funding stream dedicated to retrofitting public infrastructure to reduce their runoff, and other public initiatives would have to be explored to incentivize improvements on private / commercial property to make changes affordable, desirable, and/or implementable on a large scale across the developed portions of the watershed. That is not to say that such watershed management efforts should not be explored or implemented, but rather that they should be implemented outside of this federal project to amplify the benefits achieved from a federally supported plan and the reductions in flow may be compounded if more than one initiative can be implemented.

Figure 4-8 Inundated areas for 10% AEP FWOP (yellow) compared to Invasive Vegetation Mitigation reduced flows (blue)

It is acknowledged that this analysis was performed at a simplified screening level for the purposes of this project, comparing the standalone HEC-HMS FWOP model and the model reflecting watershed improvement measures. For a more correct comparison of the proposed watershed improvement measures to FWOP Conditions, a similar HEC-WAT analysis would need to be performed with the changes described above to the HEC-HMS model, with a range of changes to the curve number explored. The relative changes in peak discharge and volume would then be applied to the frequency FWOP hydrographs in HEC-RAS to determine true reductions in water surface elevations.

4.3. Screening of Hydraulic Measures

Engineering judgement, along with PDT discussion and collaboration, was used to identify which of the 200+ measures demonstrated promising results that were appropriate to pursue further, and which measures did not prove useful. The PDT focused on about 40 measures to analyze for further screening. Additional information regarding the screened measures can be found in the project's measure tracker spreadsheet.

Further explanation is provided in this section for the screening out of some of the measures that were determined of significant interest, specifically, the SWIFT tunnels, Ala Wai Canal microtunnels, Woodlawn bypass, Woodlawn channel widening, Palolo Valley District Park detention basin, and the Ala Wai Canal second outlet.

4.3.1. SWIFT tunnels:

The "Ala Wai Canal Flood Risk Management Project Report of the Permitted Interaction Group" completed by Oceanit in August 2020 investigated the use of Subsurface Watershed Inundation Flow Technology (SWIFT) tunnels. These tunnels were to reduce the amount of flood flow from the upper watersheds to the lower watershed to remove enough water from the 2% to 1% AEP flood to match that of the 5% to 4% AEP flood event, which is the original design capacity of the Ala Wai Canal.

These large SWIFT tunnels were investigated for the GRR Study, and multiple possible layouts were investigated, as shown in blue in Figure 4-9. The tunnels did not reduce the discharges and water surface elevations enough to make a significant difference to the water surface elevations and existing measures. The estimated costs of the tunnels were updated, and the very high costs screened these tunnels out.

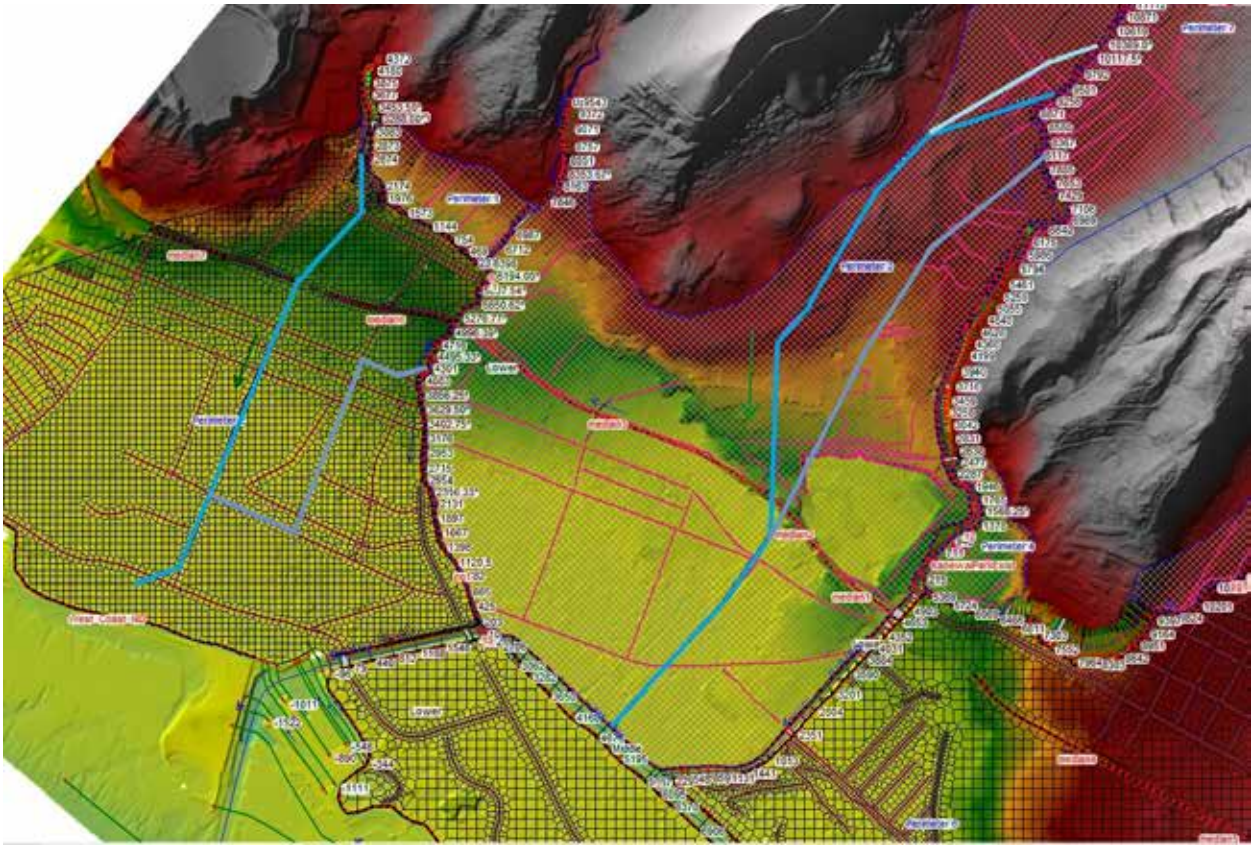

Figure 4-9: Example SWIFT Tunnel Alignments Investigated

4.3.2. Ala Wai Canal Microtunnels:

Analyzed as mechanism of passing flow from Ala Wai Canal to ocean through means of subsurface tunnels through the Wakiki area. Tunnels consisted of various sizes and configurations, and also were analyzed in multiple locations such as Kapahulu Avenue, Fort Derussy Park, and Saratoga Road. It was found that these subsurface tunnels provided little benefit in flood reduction of the Ala Wai Canal and its surrounding overbank areas. This was largely in part due to the limited slope available in the area. Much of the canal and overbank areas are not significantly higher in elevation that the ocean outlets at which the tunnels would tie into. Thus, the lack of significant slope prevents flood waters from conveying through the tunnels at an adequate flow rate to noticeable reduce flooding. There were also ecological concerns about the freshwater, possibly contaminated from the canal, flowing into the ocean near the coral reefs. The canal microtunnels are shown below in Figure 4-10 with the tunnel footprints highlighted in red.

Figure 4-10 Ala Wai Canal Microtunnels

4.3.3. Woodlawn Drive Bypass:

For the Validation Study, the analysis of this option assumed that all flow that was leaving the right bank at Woodlawn Drive Bridge near Manoa Marketplace would be captured through an inlet on Woodlawn Drive and redirected through a culvert that would run underground and along the driveway for the University's greenhouses and back into Manoa Stream. The Validation Study modeling removed the flow from the system upstream of the Woodlawn Bridge, then added the flow back in downstream. A culvert was then sized based on that flow. For this GRR Study, a culvert equal to the Validated study culvert was modeled, and the modeling showed much less impact to the water surface elevation and overland flood flows were still occurring. This was most likely due to energy losses being accounted for and the actual slope and size of the pipe being taken into consideration of the max conveyance through the bypass. The Woodland Bypass was modeled along with the Woodlawn Drive Floodwall, but the bypass did not significantly reduce the WSELs near the structures.

This measure was screened from evaluation as it did not significantly reduce water surface elevations and has a relatively high construction cost associated with it. The bypass did not negatively interact with other measures, however, and could be incorporated into the design if it is desirable to reduce WSEL on the Woodlawn Drive Floodwall. The bypass is shown in Figure 4-7.

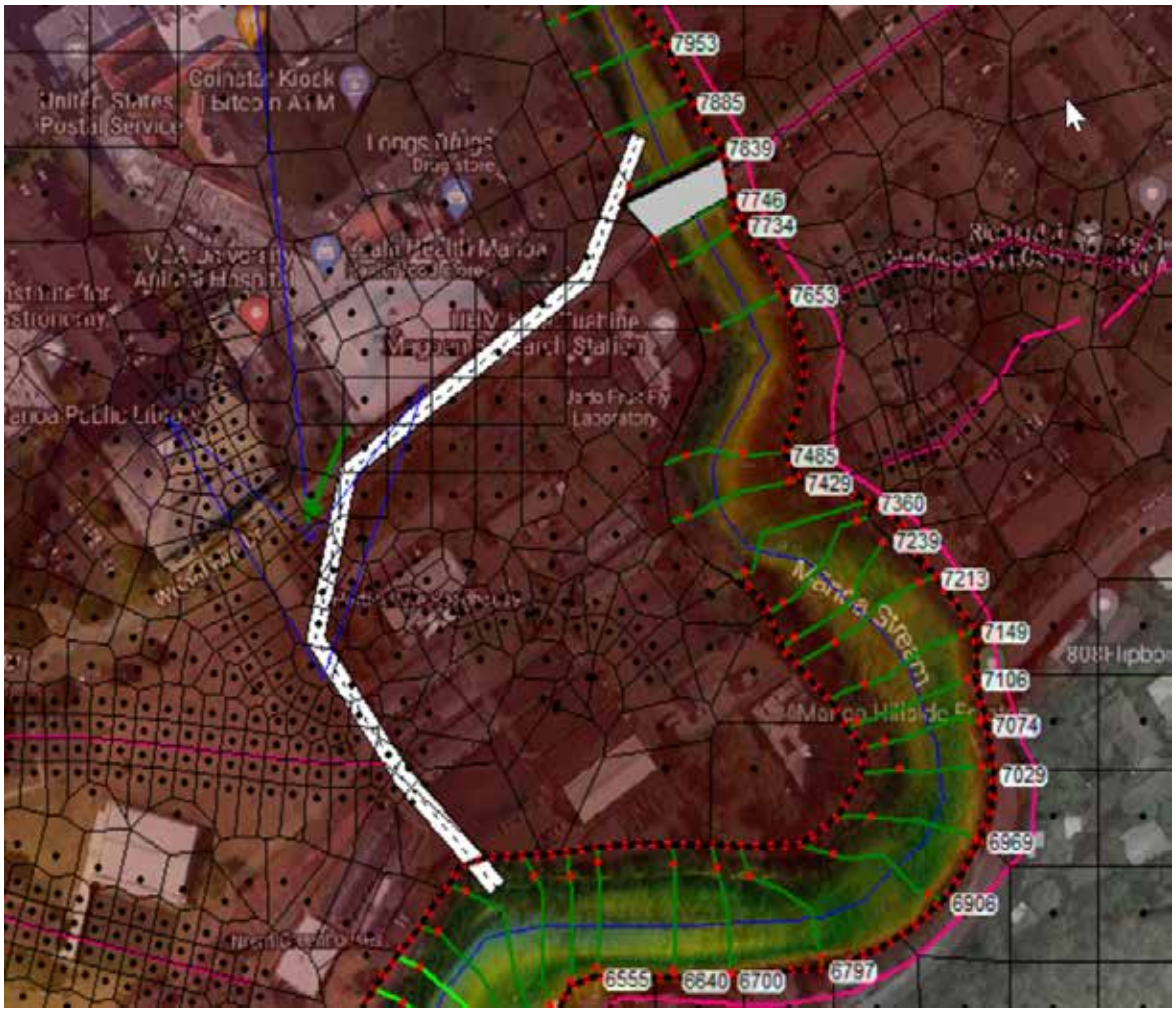

Figure 4-11 Woodlawn Drive Bypass

4.3.4. Woodlawn Channel Widening

The Woodlawn Channel Widening investigated widening the Manoa Stream channel downstream of Woodlawn Bridge where the channel naturally constricts. This measure cut into the left bank of the Manoa Stream to increase the flow conveyance in order to lower the water surface elevations through the Woodlawn bridge and reduce the overland flood flows. The location and a typical cross section in the measure area is shown in Figure 4-12. The measure was screened due to limited reduction in water surface elevation, the cost, and the fact that it did not eliminate the need for the proposed Woodlawn Drive Floodwall.

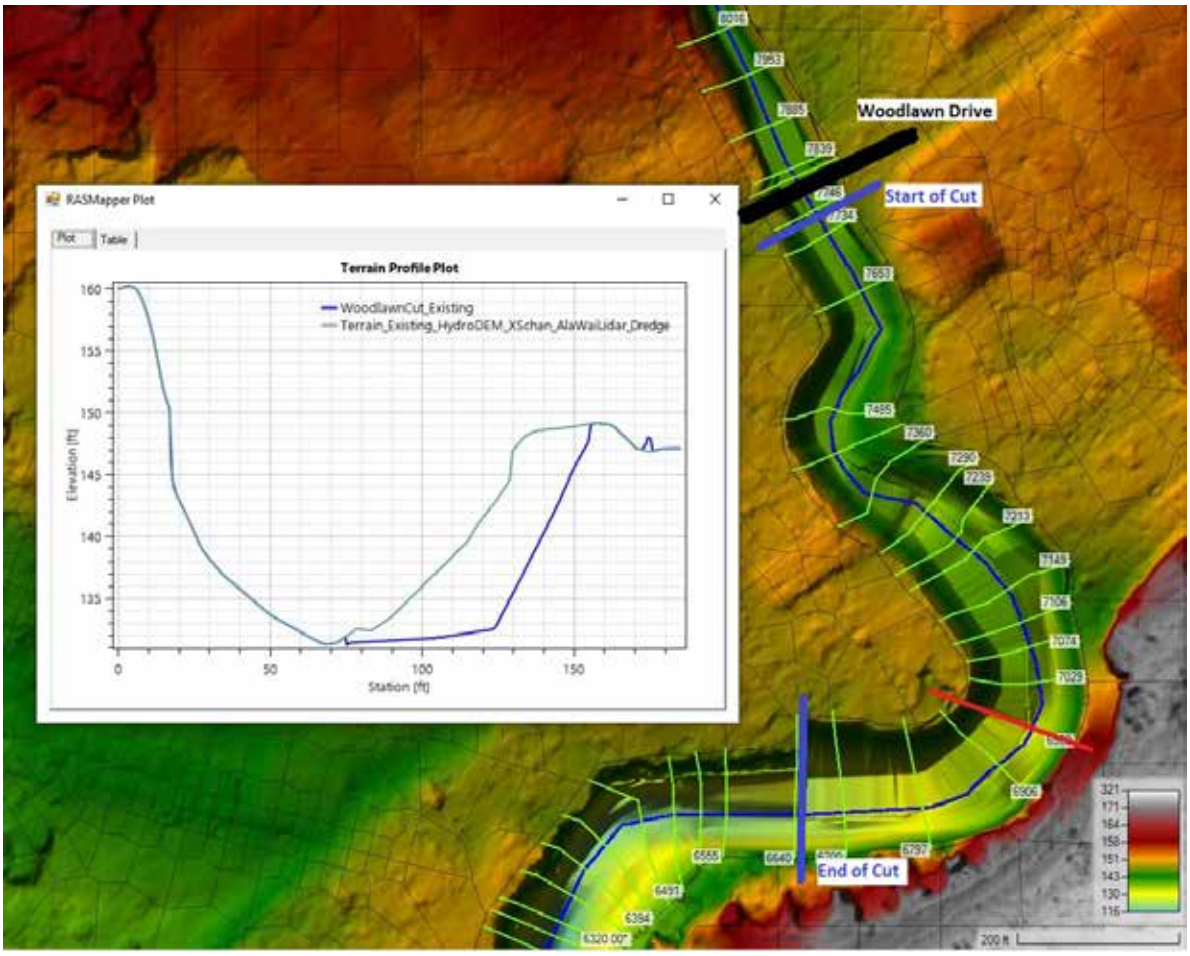

Figure 4-12: Woodlawn Channel Widening

4.3.5. Palolo District Park Detention Area

A detention area was placed around Palolo Valley District Park with a culvert diverting flow from Pukele, into the detention basin, and then into mainstem Palolo. The approximate volume of the detention basin was approximately 10 acre-ft. It was found that while the detention area captures and stores flood waters, it only shaved off a small portion of the peak flow and had limited impacts to the flooding with a large cost, therefore this measure was screened. The detention area is shown in Figure 4-13.

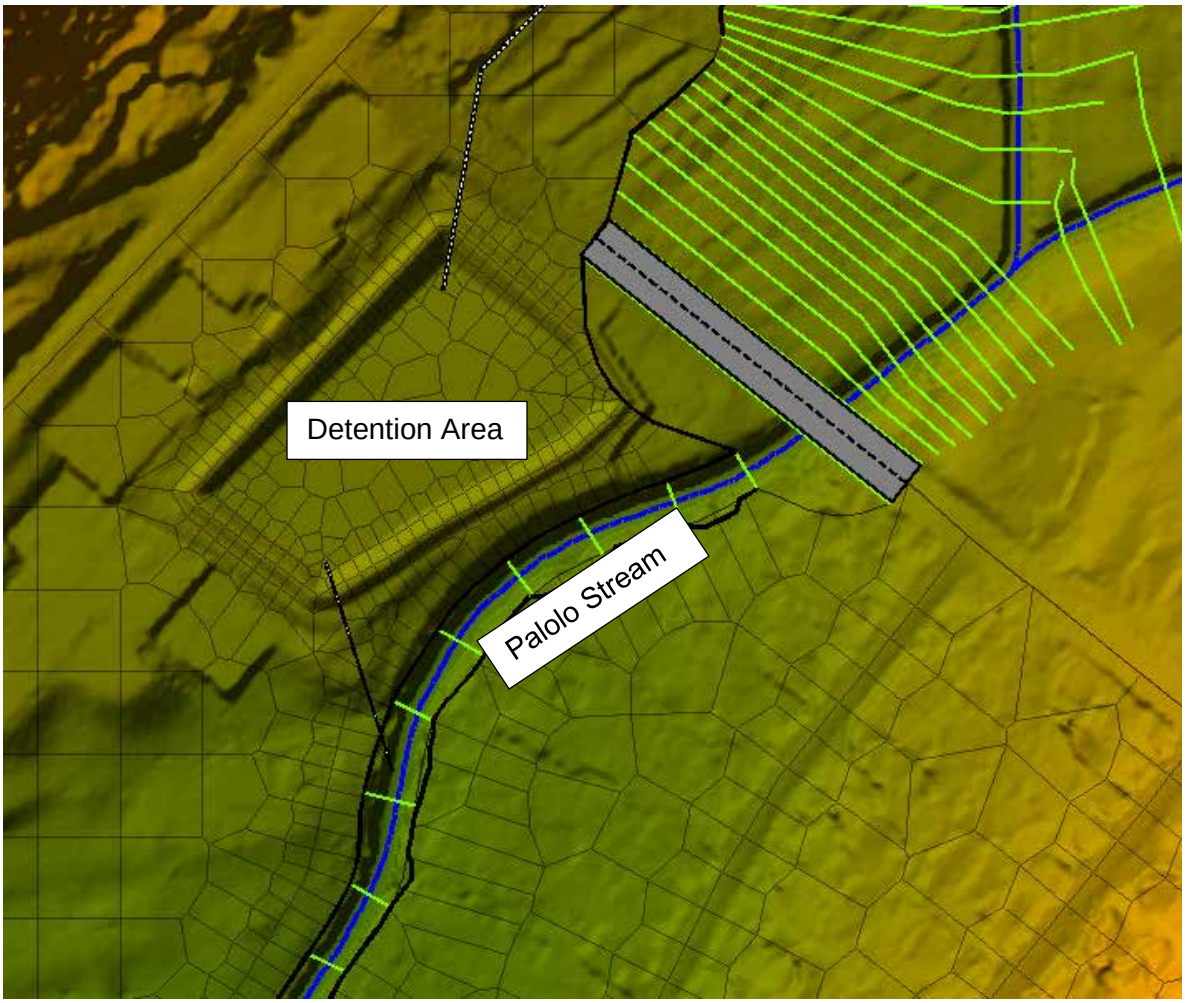

Figure 4-13 Palolo Valley District Park Detention Area

4.3.6. Ala Wai Canal Second Outlet

A second outlet of the existing Ala Wai Canal was analyzed by modeling the existing southern end of the canal back-channel to extend southward along Paki Avenue, then diverting west through Kapi'olani Park to the ocean. The width of the outlet was approximately 200ft and the depth was approximately elevations -5 to -6 feet in elevation along the daylighted portion. The intent of this measure was to enable additional flood conveyance capacity of the canal, rather than the existing condition where flood waters back up into the canal back-channel.

While hydraulic benefits were achieved, this measure was screened due to impractical costs and real estate considerations necessary to construct the outlet. There are also several environment concerns associated with this measure. Figure 4-14 shows the model schematic of the additional canal outlet.

Figure 4-14 Ala Wai Canal Second Outlet

4.4. Pumps and Floodgate Measures

The City and County of Honolulu (CCH) requested that the US Army Corps of Engineers (USACE) Ala Wai Canal Flood Risk Management General Reevaluation project delivery team (team) consider a pump station and lock system (i.e., floodgate) at the McCully Street bridge. A technical memorandum was written describing the justification for screening the pump station and floodgate at the mouth of the Ala Wai Canal as a flood risk management measure for the 1% event, then a follow up memorandum for a more frequent flood event (Philbin, 2023).

The pumps were considered at length, but screened during the development of the final array due to the following reasons:

a. Pumping of the canal ahead of a storm is not feasible given the sheer volume of water to excess and the rate of ramp-up time needed for pumps to safely excess water given the flashy nature of storms.

b. Pumping of the canal ahead of a storm would impact the structural stability of the existing canal walls, as the hydrostatic pressure of the water in the canal provides stability for the

existing condition of the walls. As the Ala Wai Canal is a historic property, there are many constraints, and ensuring structural stability is required.

c. Pumps were sized (in volume of water) at the Ala Moana Harbor for various storm events. A cost estimate was developed for a 20,000 cubic feet per second (approximately 9 million gallons per minute) pump, slightly larger in size than what is anticipated to be needed for this study. The estimate indicates the pump station would cost roughly $1.4-$1.8 billion.

d. Pumps at the canal would not reduce the need for other measures within the watershed. At the cost aforementioned, the study would not be able to proceed with any additional measures.

e. In 2020, a Value Engineering (VE) exercise was performed on a pump station at the mouth of the canal. The exercise was performed by the USACE New Orleans District, with review from private sector Architectural/Engineering firms.

The assumptions were as follows:

i. Performance was evaluated for the 1% Annual Exceedance Probability (AEP) (i.e. 100-year) event for a 24-hour storm.

ii. Two 65 ft by 15 ft miter gates were used in the simulation. Gates were open up to 7 ft if the head difference between the ocean and the canal was favorable.

iii. Ten 96- inch axial flow 800 horsepower pumps were used in the simulation. The pumps would drain the canal to elevation -5 ft LMSL in anticipation of the event.

iv. The structure was placed upstream of the Ala Moana Boulevard bridge.

Results are as follows:

i. The canal continues to fill despite outflow through the pumps and gates. The local runoff and riverine flow contribute greater water than what can be pumped through the structure.

ii. The pump and gate system has localized effects during the leading and lagging legs of the storm (beginning and end) but fails to provide benefits across the length of the canal due to its mild slope.

iii. In the VE simulation, the pump station is continuously working to expel water. Pumps typically need to cycle on and off to function properly and maintain efficiency throughout its life cycle.

iv. Pumping results in a drop in water surface elevation for the 1% annual exceedance probability event of 0.1 feet in the vicinity of the Ala Wai Community Park.

v. Pumping has a negligible impact to water surface elevation in the vicinity of the Manoa-Palolo Canal.

The PDT was asked to further evaluate the lock and pump system at a more frequent event

(i.e., the 5% AEP, or 20-year event). A multidisciplinary team of engineers, scientists, and economists reanalyzed the lock and pump system under a more frequent storm event. The results of that analysis are listed below.

a. Flow estimates at the site of the proposed lock and pump system were compared for the 1% (approximately 15,000 cfs), 2% (14,200 cfs), and 5% (12,750 cfs) AEP events. The difference in flow between the 1% event and the 5% event is less than 3,000 cubic feet per second, or 550 gallons per minute.

b. The previous cost evaluation for a lock and pump system for a 20,000 cfs pump, slightly larger than the 1% AEP event, was approximately $1.4 billion. The cost estimate for a lock and pump system for the 5% AEP event is approximately $1.1 billion. Thus, the difference in cost for the lock and pump system between these events is less than $258 million. Cost estimates developed for this measure include the pumps, pump house, lock/floodgates, and parapets. Costs are inclusive of design, construction, and administrative costs. The cost estimates do not include costs associated with the construction of new canal walls, which would be required to ensure structural stability during periods when pumping of the canal would result in the loss of hydrostatic pressure that provides stability for the existing walls. The cost estimate provided does not include annual O&M expenses.

c. The lock and pump system will not reduce the need for floodwalls entirely, as demonstrated by the Value Engineering exercise performed in 2020. The lock and pump system would reduce the required height of the floodwalls around the canal. However, preliminary results indicate the reduction in floodwall height would only be a few inches—a change that would have minimal impact on overall cost of the floodwalls. The typical floodwall cross section along the canal comprises of an above-ground structure and a below ground sub-structure. Due to the subsurface conditions, the floodwall substructure consists of macropiles that would be driven 40 feet into the ground. A reduction in height of the floodwall (from a few inches to a few feet) does not correlate to a reduction in depth or material of the floodwall substructure. Therefore, the costs of the floodwall are comparable with or without the pump station in place.

d. Environmental impacts associated with the lock and pump system would be substantial due to the expected changes in the volume of water within the canal and discharge of water to the nearshore coastal habitats. Further discussion of the environmental impacts is not provided within this memorandum.

The analyses discussed within this memorandum indicate that a lock and pump system would not be effective or efficient at reducing flood risk during the range of events that drive risk within the Ala Wai watershed (i.e., 1%, 2%, and 5%). As a result, the team recommended screening this measure from further consideration.

4.5. Summary of Screening Outcomes for determining the Array of Alternatives

Table 4-6 shows some of the measures that were modeled to analyze the impacts to water surface elevations and if they should be further retained or screened. The official measure tracking spreadsheet lists the reasons why the measures were retained or screened. The retained measures are further described under the Final Array of Alternatives in Section 5.

Table 4-6: Screening of Measures for Final Array of Alternatives

Measure	Description	Outcome
Kapahulu Bypass	Subsurface culvert connecting the upstream end of the Ala Wai Canal back channel to the ocean along Kapahulu Avenue.	Screened
Ala Wai Golf Course Detention Area	Berm along Ala Wai Golf Course with inline structure on Palolo to create flood storage on golf course.	Retained
Ala Wai Canal 2nd Outlet	2nd outlet of Ala Wai canal represented by a daylighted stream connecting the current upstream end of the Ala Wai Canal back channel to the ocean by following approximate path of Paki Avenue, then bending west through Kapiolani Park.	Screened
Ala Wai Canal Floodwall	Floodwalls ranging from 3-5 feet in height, offset from existing canal walls.	Retained
Kaimuki Levee	Levee structure around Kaimuki High School recreational fields preventing inundation in residential areas east of Kaimuki High School	Retained
Ala Wai Canal Microtunnels	Subsurface culverts connecting the Ala Wai Canal to the ocean along Kapahulu	Screened

Measure	Description	Outcome
	Avenue, Fort Derussy Park, and Saratoga Road.	
Paki Avenue Bypass	Subsurface culvert connecting the upstream end of the Ala Wai Canal back channel to the ocean along Paki Avenue.	Screened
Ala Wai Canal Dredging	Dredging of the Ala Wai Canal from the most upstream end of the canal back channel to the Ala Moana Bridge.	Screened
Kapiolani Park Detention Area	Detention area placed within Kapiolani Park, with entire area of park used.	Screened
Ala Wai Canal Pump Station	Pump station along Ala Wai Canal used to assist in draining of Ala Wai Golf Course.	Screened
Koali Road Floodwall	Floodwalls on Manoa Stream along Koali Road.	Retained
Makiki Detention Area	Detention structure at Makiki District Park.	Retained
Kanaha Floodwall	Floodwall placed along Kanaha Ditch.	Retained
Woodlawn Bypass	A bypass culvert was placed at an upstream location on the Manoa Stream upstream and re-entering further downstream.	Screened
Woodlawn Detention Area	Detention structure at Woodlawn.	Retained
Woodlawn Drive Floodwall	Floodwall placed along Manoa Stream across Woodlawn Drive	Retained
Manoa Detention Area	Detention structure at Manoa Valley District Park.	Retained

5. Final Array of Alternatives

Throughout the screening process several measures were retained based on hydraulic performance, potential benefits, and practicality of each measure. These measures were then combined into sets of alternatives to be further evaluated. Upon further screening of measures, an initial array of alternatives was identified from the retained measures. This initial array consisted of combining measures to form cornerstones centered around specific flood reduction concepts. The initial array of alternatives determined by the PDT was identified as follows:

Alternative 1: Storage Cornerstone
Alternative 2A: Conveyance Cornerstone (Existing Infrastructure/Bypasses)
Alternative 2B: Conveyance Cornerstone (Floodwall)
Alternative 2C: Conveyance Cornerstone (2nd Outlet/Daylight)
Alternative 3: Tunnel Cornerstone
Alternative 4A/B: Natural and Nature-Based Cornerstone
Alternative 5: Combined Plan
Alternative 6: Non-Structural

These initial alternatives were the further evaluated by the PDT using the plan formulation process. This further analysis resulted in refining the alternatives into a final array of alternatives. These alternatives, along with the measures used in each alternative, are shown in Table 5-1.

Table 5-1 Final Array of Alternatives

Alternative 1		Alternative 2B		Alternative 5
Kanaha Floodwall		Kanaha Floodwall		Kanaha Floodwall

Kaimuki High School Floodwall		Ala Wai Canal Floodwall		Ala Wai Canal Floodwall (with Kaimuki Extension)
Ala Wai Golf Course Detention Basin				Ala Wai Golf Course Detention Basin

5.1. Alternative 1

Alternative 1 was formulated to maximize flood storage throughout the basin by utilizing multiple detention basins. Additional measures were also supplemented to provide added benefits through means of floodwalls and berms. This alternative included the Kanaha Floodwall and Maikiki Park Detention Basin, the Manoa Park Detention Basin, the Woodlawn Drive Floodwall,

the Koaki Road Floodwall, the Kaimuki High School floodwall, and the Ala Wai Golf Course Detention Basin.

5.1.1. Kanaha Floodwall and Makiki Detention Park

A floodwall placed along Kanaha Ditch will be approximately 6ft in height along the right bank. A detention basin will be built at the Makiki District Park. This measure is in all three of the final alternatives modeled. Figure 5-1 shows the general location of the Kanaha Floodwall and Makiki District Park Detention. Figure 5-2 shows the profile plot of the Kanaha Floodwall. Figure 5-3 shows the general profile plot of the Makiki District Park Detention Area. Figure 5-4 shows the elevation-storage plot of the Makiki Park detention area.

The approximate dimensions of the detention basin are 450 feet long by 250 feet wide with a top elevation of 62 ft MSL and an average excavation depth of 6-10 feet. This produces approximately 21.6 ac-ft of storage to provide required detention volume.

The inlet culvert was modeled as a 20 ft by 4 ft concrete box culvert with connection from the Kanaha Stream to the storage area. The outlet culvert is a 5 ft diameter culvert that drains into the Makiki Stream after the stream daylights downstream of the H1 Freeway.

It is estimated that the emptying time will be about 1-2 days, depending on the final culvert sizing after optimization and design.

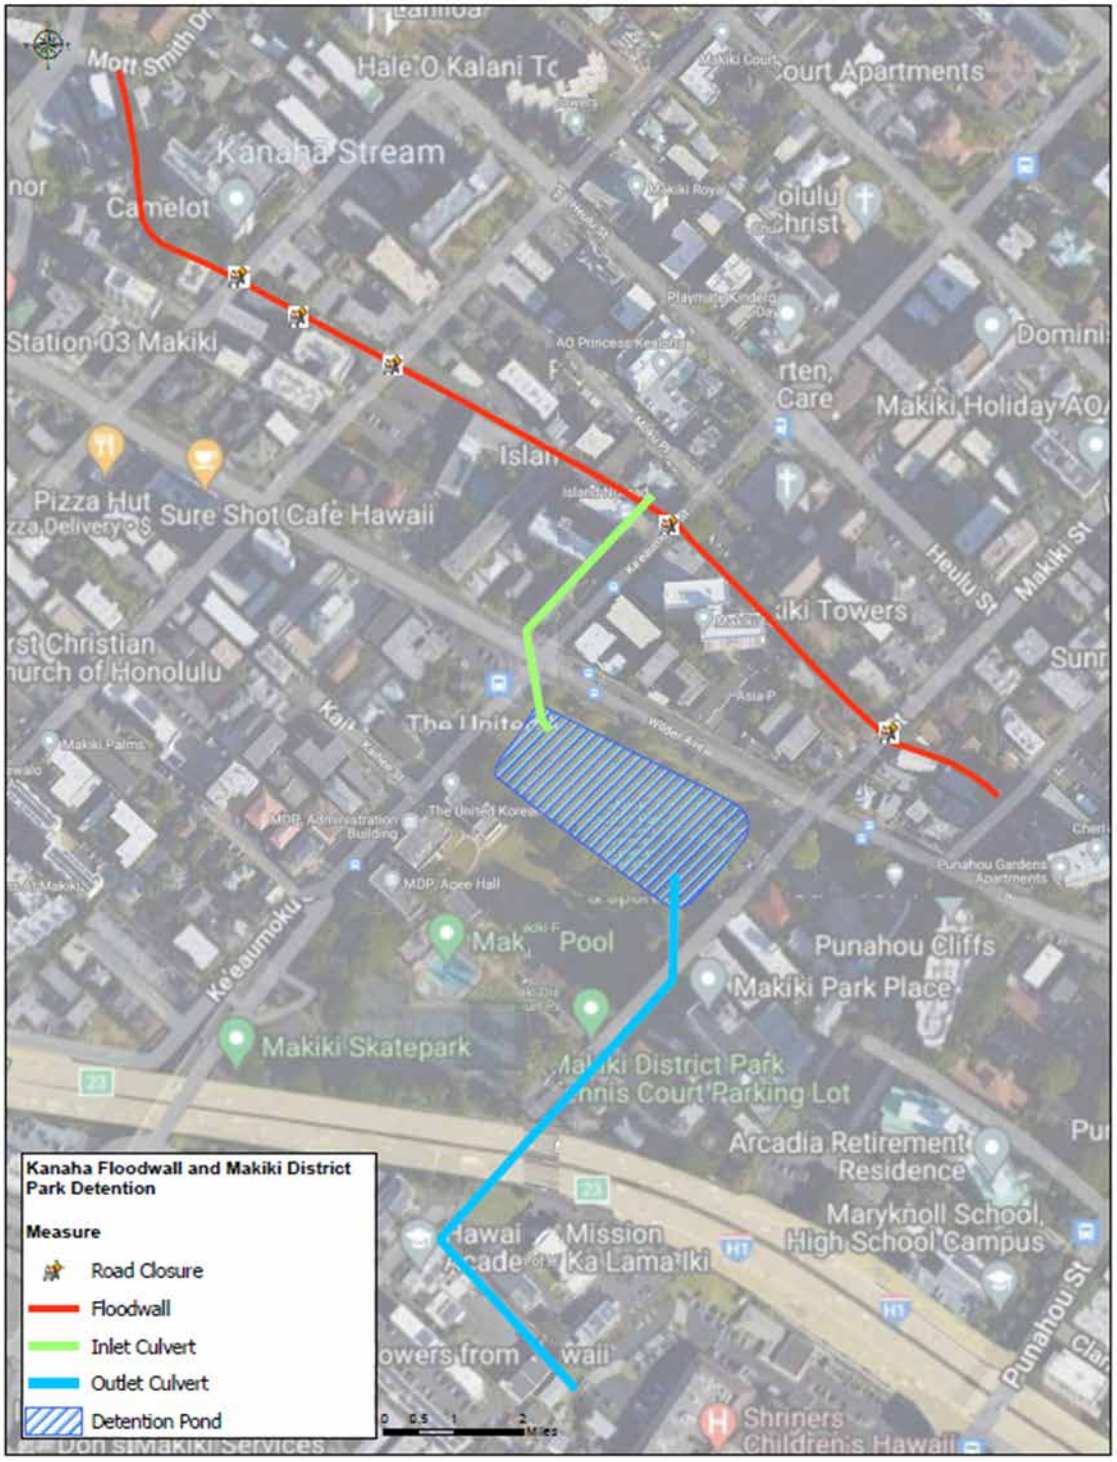

Figure 5-1 Kanaha Floodwall and Makiki District Park Detention Area

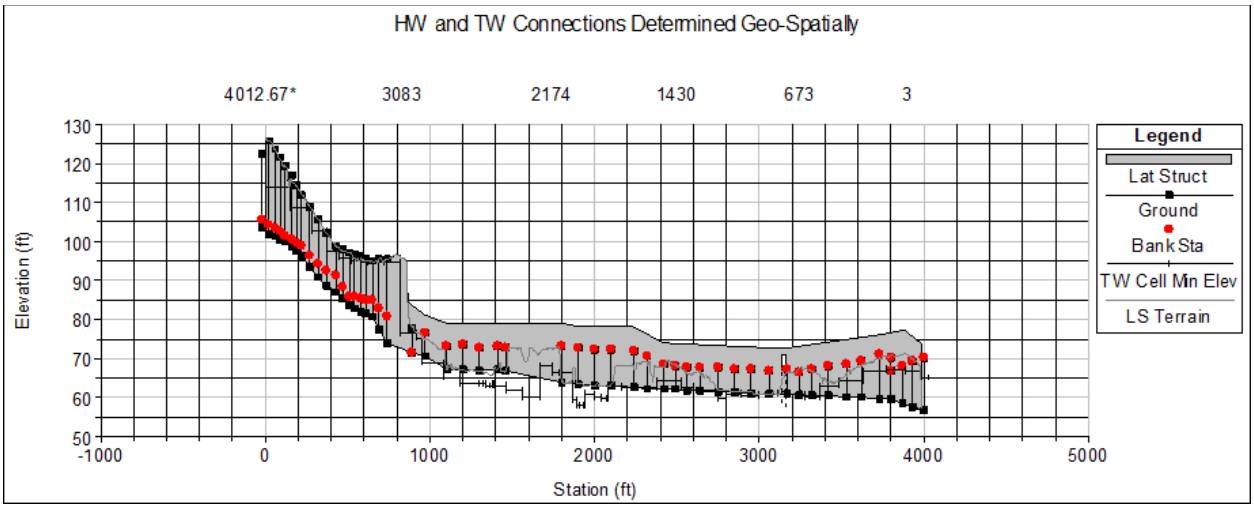

Figure 5-2 Kanaha Floodwall Profile

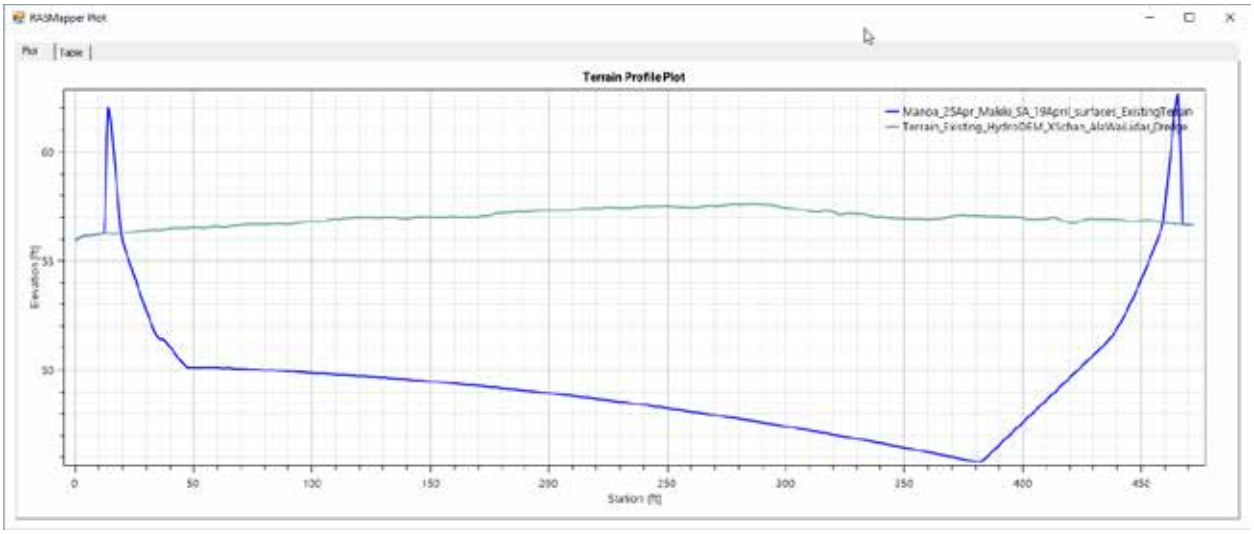

Figure 5-3 Makiki District Park Detention General Profile

	Vol-Elev Volume (acre-ft)	Vol-Elev Elevation (ft)
1	0.000	44.950

23	21.640	62.000

Figure 5-4 Makiki District Park Detention Area Storage Curve

5.1.2. Manoa District Park Detention Area:

A detention structure would be constructed at Manoa Valley District Park. The approximate dimensions of the detention basin are 700ft long by 600ft wide with a top elevation of 172 ft MSL at the downstream end. The wall elevation will need to be higher along the Manoa Stream to account for higher water levels in the upstream portion of the District Park boarder.

The detention basin would have an average excavation depth of 6-10 feet. This produces approximately 54.1 ac-ft of storage. Please note that the footprint of the detention area will be slightly reduced during the optimization phase, and the total volume of storage will be less than 50 acre-feet. This will ensure the detention basin is not so large as to qualify as a dam.

The inlet structure will be a 15ft x 4.5ft box culvert connecting from the Manoa Stream upstream of the bridge entrance to the Manoa District Park. The outlet structure is modeled as a 2 ft culvert exiting into the drain at the downstream end of the Manoa District Park which flows into the Manoa Stream. It is estimated that the emptying time will be about 1-2 days, depending on the final culvert sizing after optimization and design.

Figure 5-4 shows the top of wall elevations for the Manoa District Park Detention Area. Figure 5-5 shows the general profile plot for the Manoa District Park Detention Area. Figure 5-6 shows the storage curve for the detention area. And Figure 5-7 shows the Manoa District Park Detention Area.

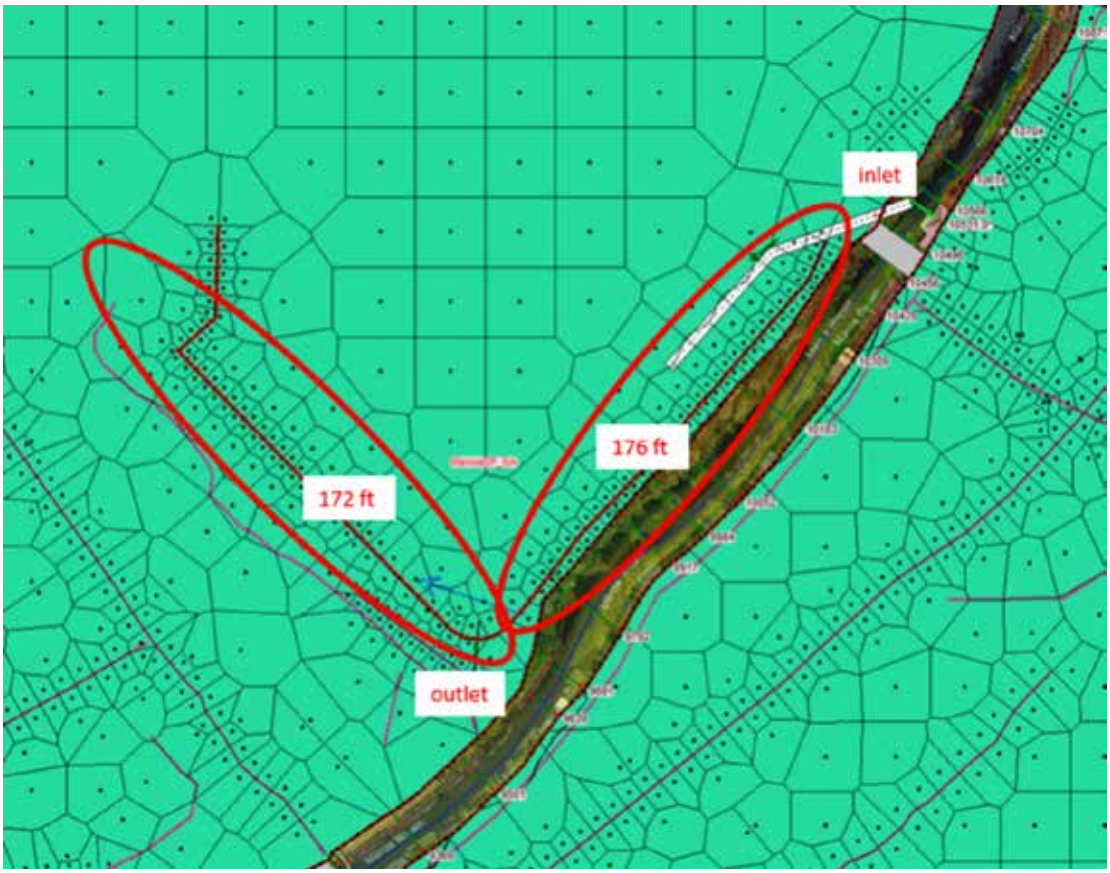

Figure 5-5 Manoa District Park Detention Top of Wall Elevations

Figure 5-7 Manoa District Park Detention Area Storage Curve

Figure 5-8 Manoa District Park Detention Area

5.1.3. Woodlawn Drive Floodwall

A floodwall will be constructed along the right bank of the Manoa Stream to contain the floodwaters that leave the Manoa upstream of Woodland Drive. The wall will be approximately 6ft in height. This floodwall crosses Woodlawn Drive and is intended to protect the area west and south of the Manoa Stream at this location. This floodwall would prevent the overland flooding that moves overland all the way down to the university of Hawaii. Figure 5-9 shows the Woodlawn Drive Floodwall location. Figure 5-10 shows the Woodlawn Drive Floodwall profile.

Figure 5-9 Woodlawn Drive Floodwall

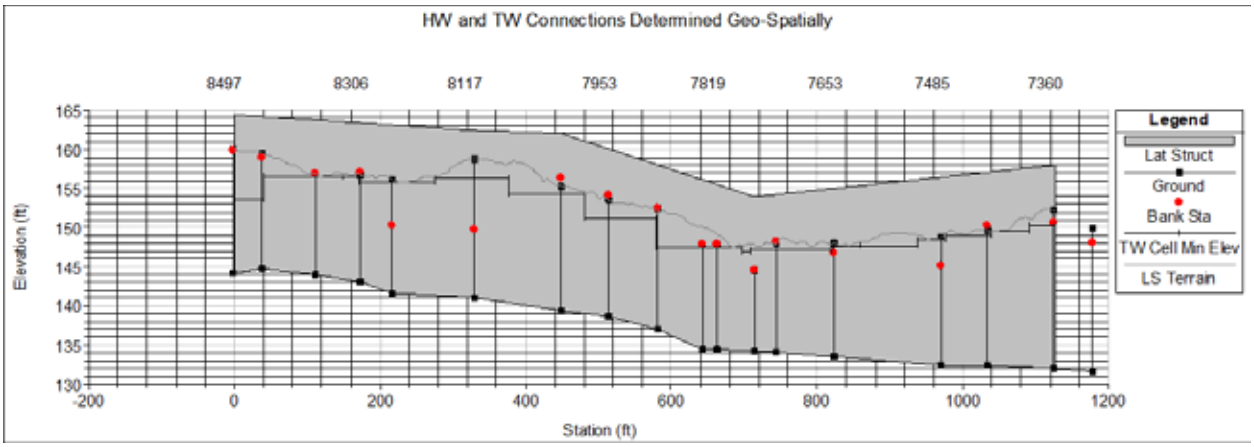

Figure 5-10 Woodlawn Drive Floodwall Profile

5.1.4. Koali Road Floodwall

A floodwall will be constructed along the left bank of the Manoa Stream to contain the floodwaters that leave the Manoa at the Kanewai Community Park and along Koali Road and also along the right bank of the Palolo Stream. The floodwalls will be a maximum height of 6 ft, but they may be lower in areas. Culverts were included along floodwall to drain areas inundated at higher flows due to overtopping of the floodwall. The Koali Road Floodwall is intended to protect the neighborhood and school just south of the Kanewai Community Park from flooding. Figure 5-11 shows the Koali Road Floodwall location. Figure 5-12 shows the Koali Road Floodwall profile plot along the Manoa Stream, and Figure 5-13 shows the Koali Road Floodwall along the Palolo Stream.

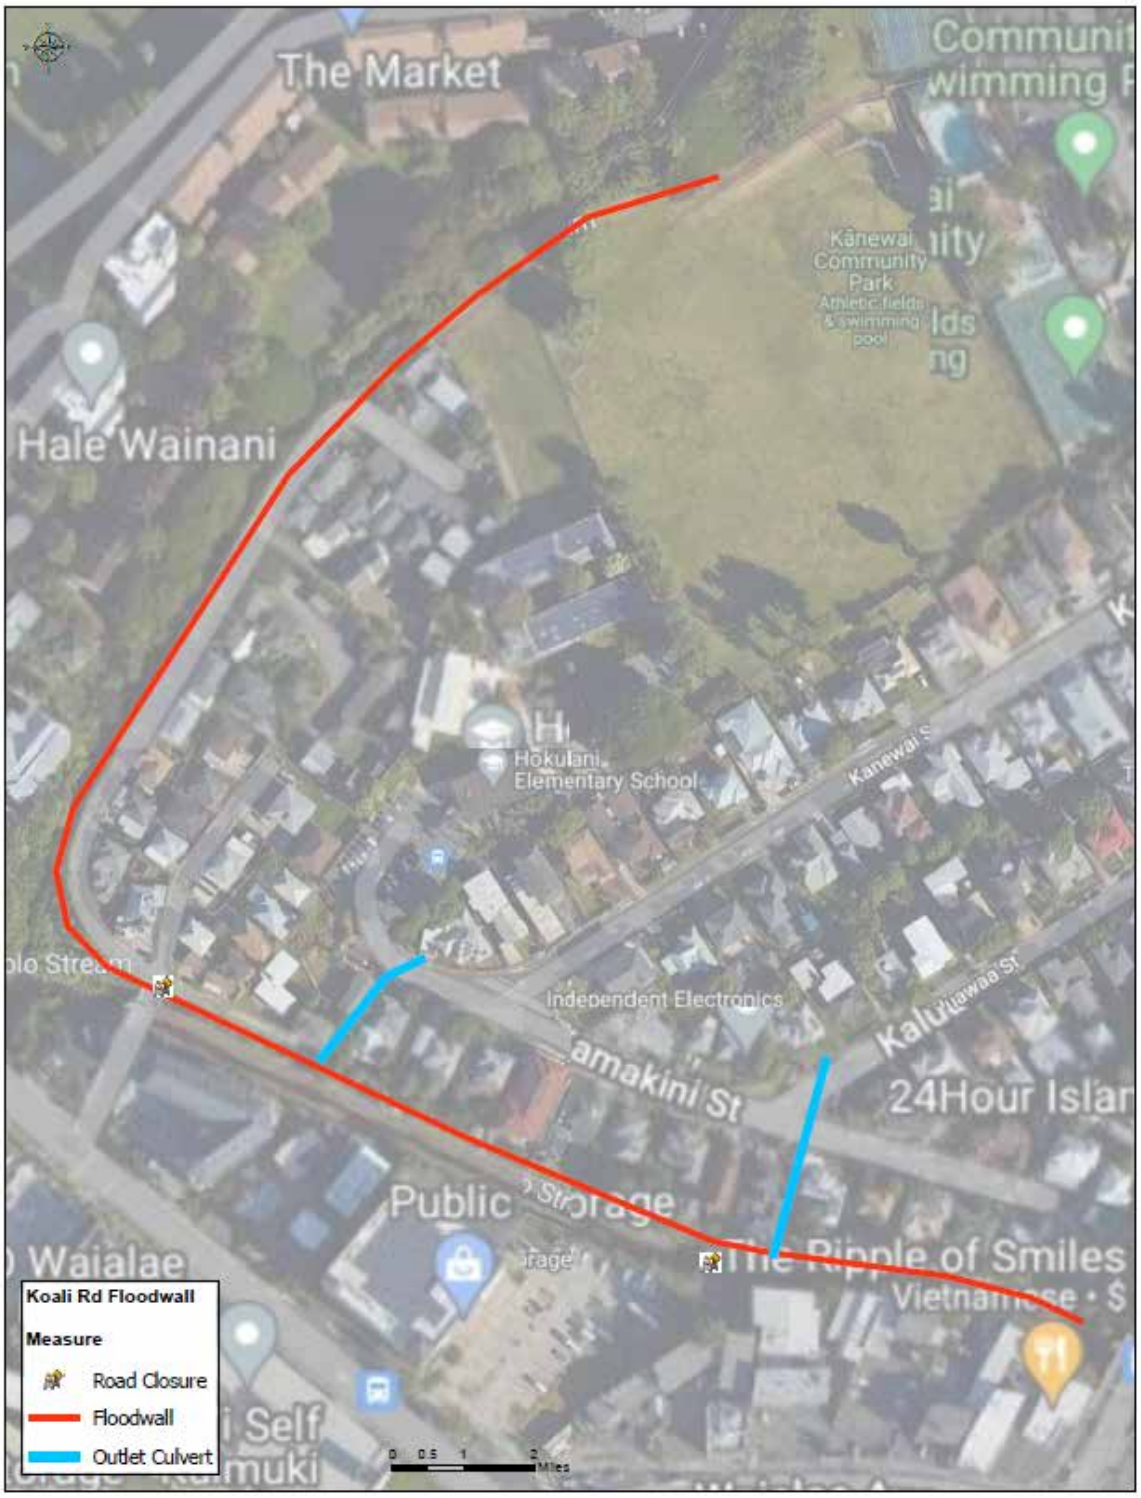

Figure 5-11 Koali Road Floodwall

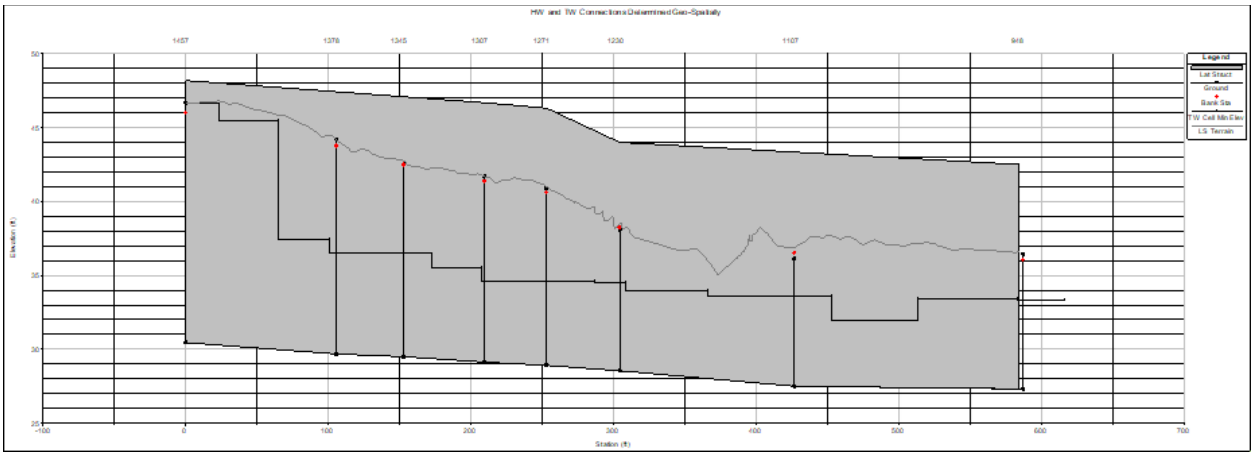

Figure 5-12: Koali Road Floodwall Profile Along the Manoa Stream

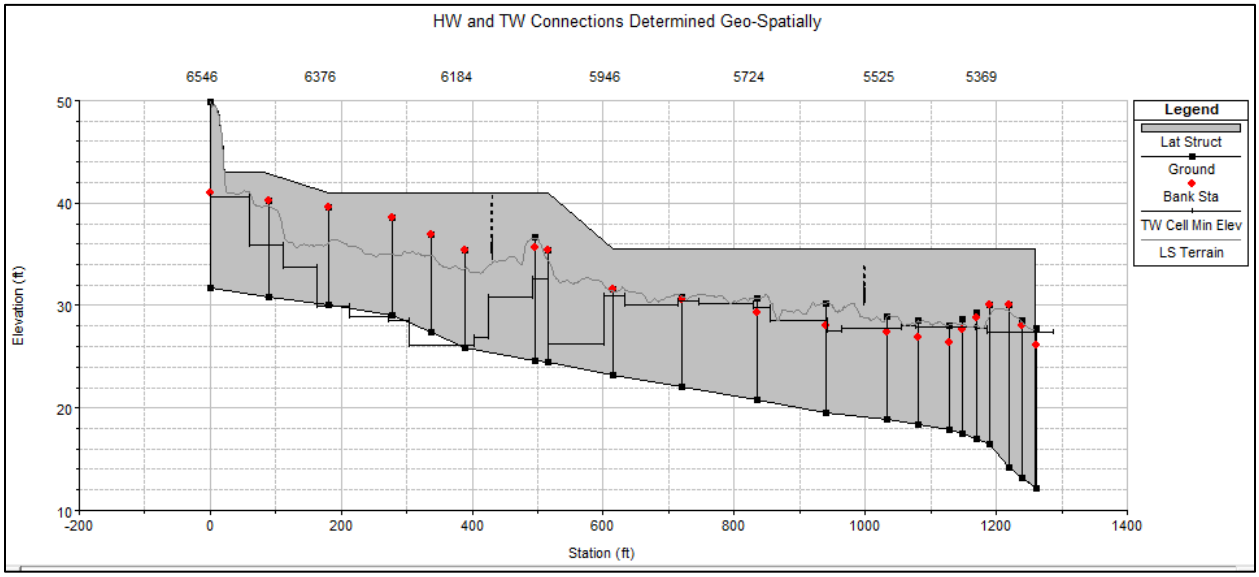

Figure 5-13: Koali Road Floodwall Profile Along the Palolo Stream

5.1.5. Kaimuki High School Floodwall and Ala Wai Golf Course Detention Area

The Kaimuki High School Floodwall structure was designed to be approximately 6ft in height around Kaimuki High School recreational fields, preventing inundation in residential areas east of Kaimuki High School.

The Ala Wai Golf Course Detention Area consists of placing an inline structure on the Palolo Stream with five 3 ft diameter culverts to pass normal flows while diverting high flows to the golf course for storage. The detention storage was created by utilizing a berm surrounding the golf course on the Northern and Eastern perimeter and along the banks of the Manoa-Palolo Canal and the Ala Wai Canal, and no excavation is to be utilized due to the high groundwater. The

floodwalls are expected to be a maximum of 6 feet tall. Three drainage structures were placed where the Ala Wai Golf Course meets Ala Wai Canal to assist in draining the golf course after a storm event. It is estimated that the emptying time will be about 1.5-2 days, depending on the final culvert sizing after optimization and design.

Figure 5-14 shows both the Kaimuki High School Floodwall and Ala Wai Golf Course Detention area. Figure 5-15 shows the Kaimuki High School Floodwall profile plot. Figure 5-16 shows the inline structure required to divert flows into the Golf Course detention basin. The Ala Wai Golf Course detention basin is bounded by the Manoa-Palolo Canal to the west, the northern and eastern perimeter of the Golf Course, and by the Ala Wai Canal to the south. The profile views of these floodwalls and berms is show in Figure 5-17, Figure 5-18, and Figure 5-19, respectively.

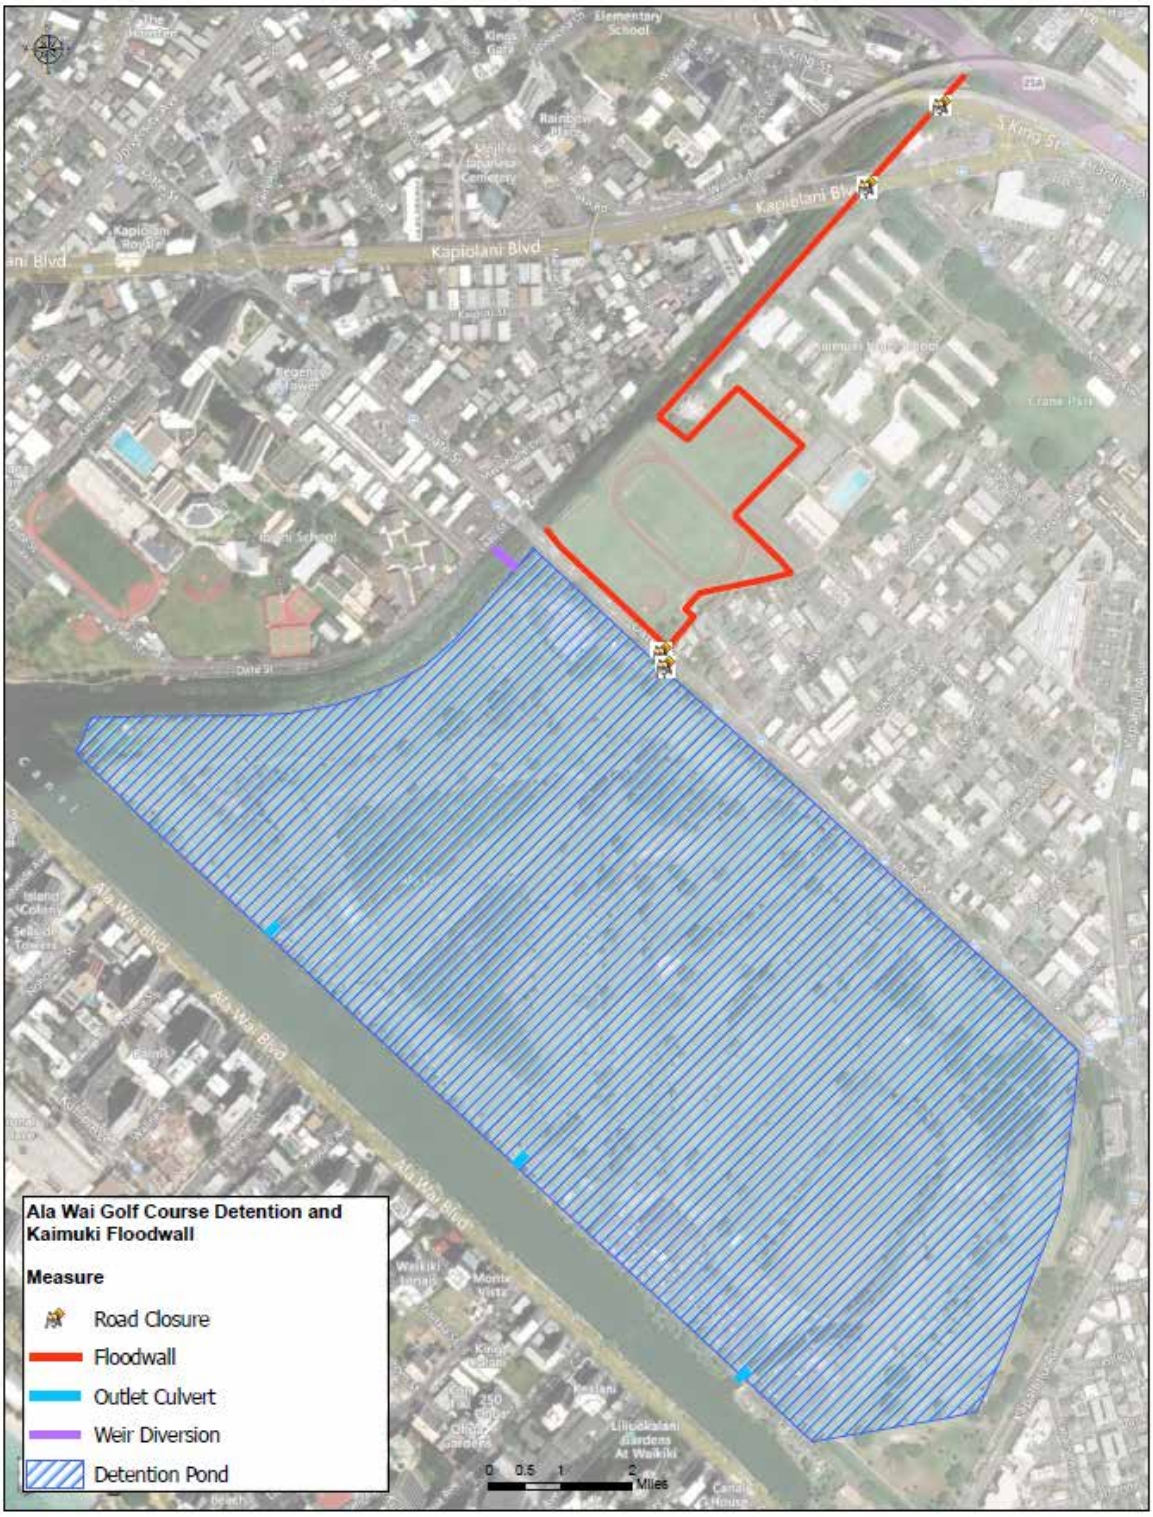

Figure 5-14 Kaimuki High School floodwall and Ala Wai Golf Course Detention Area

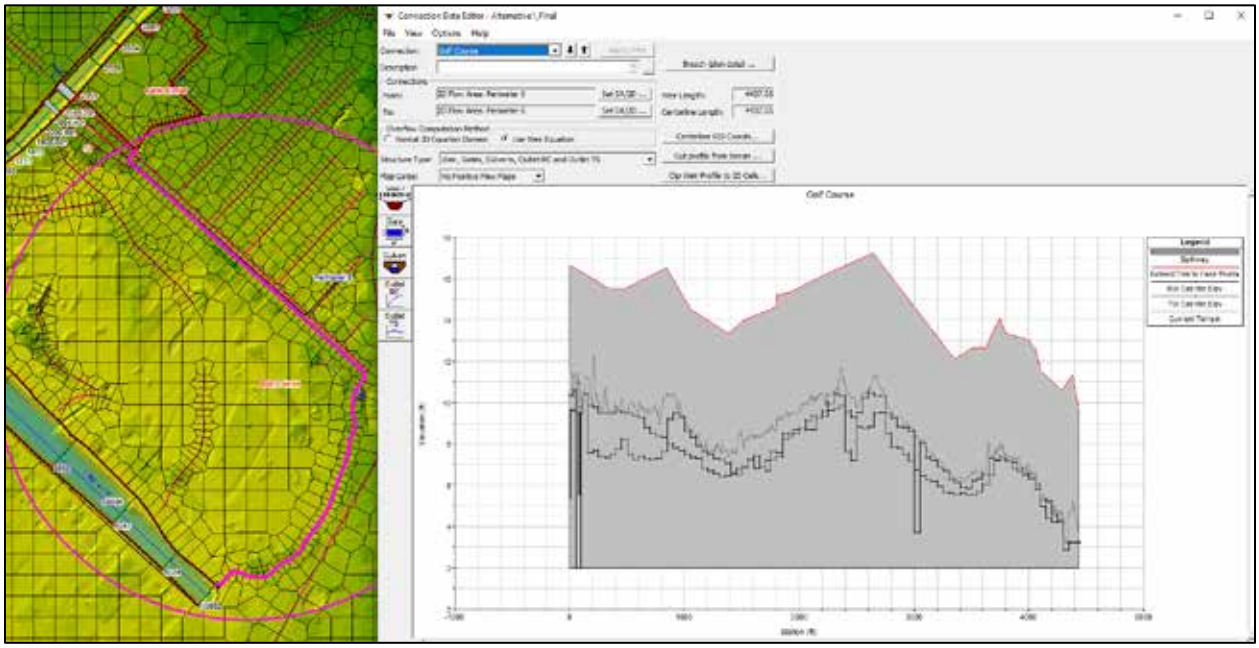

Figure 5-18: Golf Course Detention Area Profile of Northern and Eastern Walls

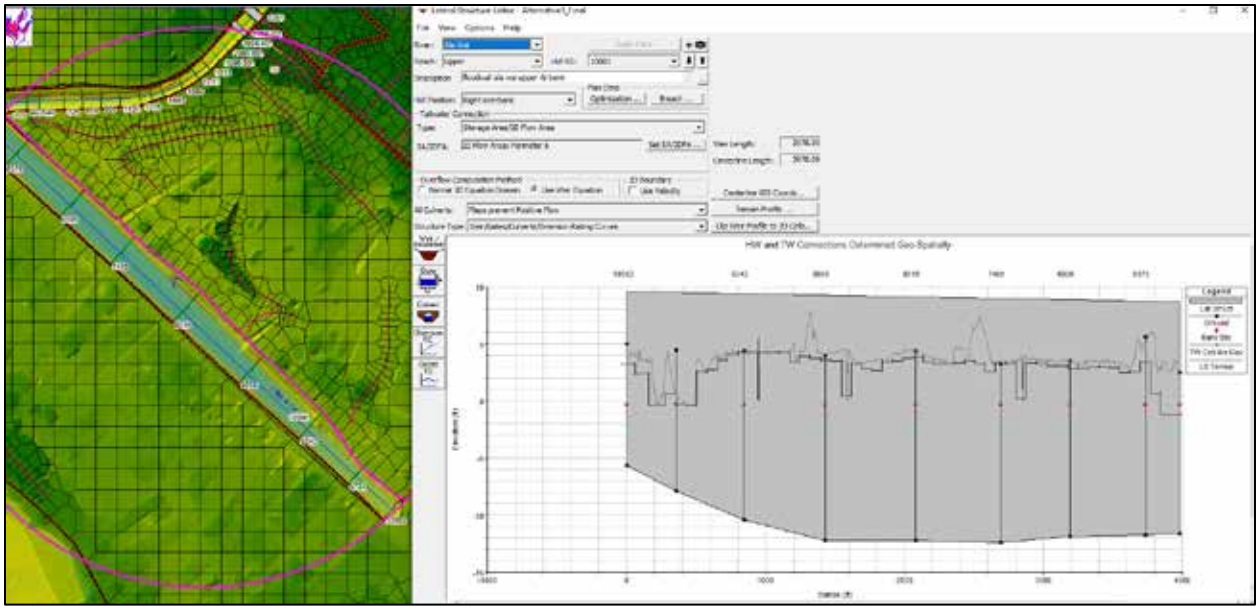

Figure 5-19: Golf Course Detention Area Profile Along the Ala Wai Canal

5.2. Alternative 2B

Alternative 2B was identified as the conveyance cornerstone as it was intended to maximize conveyance of flood waters throughout the main channels in the watershed during a flood event. This was accomplished by utilizing floodwalls throughout the basin to contain flood waters in the main channels and pass flows downstream, reducing the chance of flood waters from inundating the overbank areas.

5.2.1. Kanaha Floodwall and Makiki District Park Detention Area

The Kanaha Floodwall and Makiki District Park Detention Area were utilized in an identical manner here as in Alternative 1, however wall heights differed slightly in some locations. Information on these measures can be found in section 5.1.1. Figure 5-21 shows the floodwall profile, where the most notable differences in wall heights are from the middle section down to the lower section, which were actually lower than the 6 ft wall height.

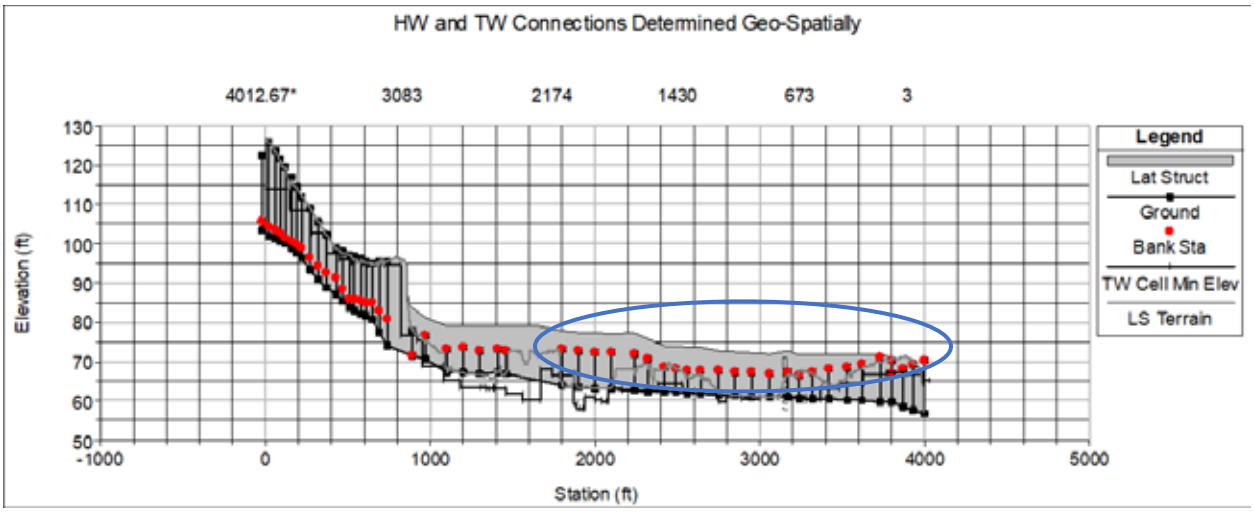

Figure 5-20 Kanaha Floodwall with Lower Wall Heights

5.2.2. Woodlawn Drive Floodwall

The Woodlawn Drive Floodwall was utilized in an identical manner here as in Alternative 1. Information on this measure can be found in section 5.1.3.

5.2.3. Koali Road Floodwall

The Koali Road Floodwall was utilized in an identical manner here as in Alternative 1. Information can be found in section 5.1.4.

5.2.4. Kaimuki High School Floodwall and Ala Wai Canal Floodwall

The Kaimuki High School Floodwall was utilized in an identical manner here as in Alternative 1. Information can be found in section 5.1.5.

For Alternative 2B, the Kaimuki High School was combined with the Ala Wai Canal Floodwall measure instead of the Ala Wai Golf Course Detention Area.

The Ala Wai Canal Floodwall was modeled with the left bank floodwall extending from the most upstream end of the Ala Wai Canal back channel to the mouth of the canal. The right bank of the canal extends from the right bank near Lunalilo Parkway of the Manoa-Palolo Canal to the confluence with the Ala Wai Canal, then continues on the right bank of the Ala Wai Canal to the mouth of the canal. Floodwall heights were approximately 6 ft. The floodwall consisted of 6 small drainage structures ranging from 2-5 feet in height and width. Also included with the floodwall were 9 road close structures necessary for high-flow flood events. No inline structure was required to divert water into a detention basin as for this alternative, water is meant to just flow in and out of the Golf Course area like a normal connected floodplain. The Golf Course berm is also approximately 6 ft in height and bounds the Golf Course on the north and east. The west and south are existing wall heights. Figure 5-21 shows the Ala Wai Canal Floodwall combined with the Kaimuki High School Floodwall. Figure 5-22 shows the Ala Wai Golf Course

berm profile, Figure 5-23 shows the Kaimuki High School floodwall profile, and Figure 5-24 shows a typical profile of the Ala Wai Canal Floodwall.

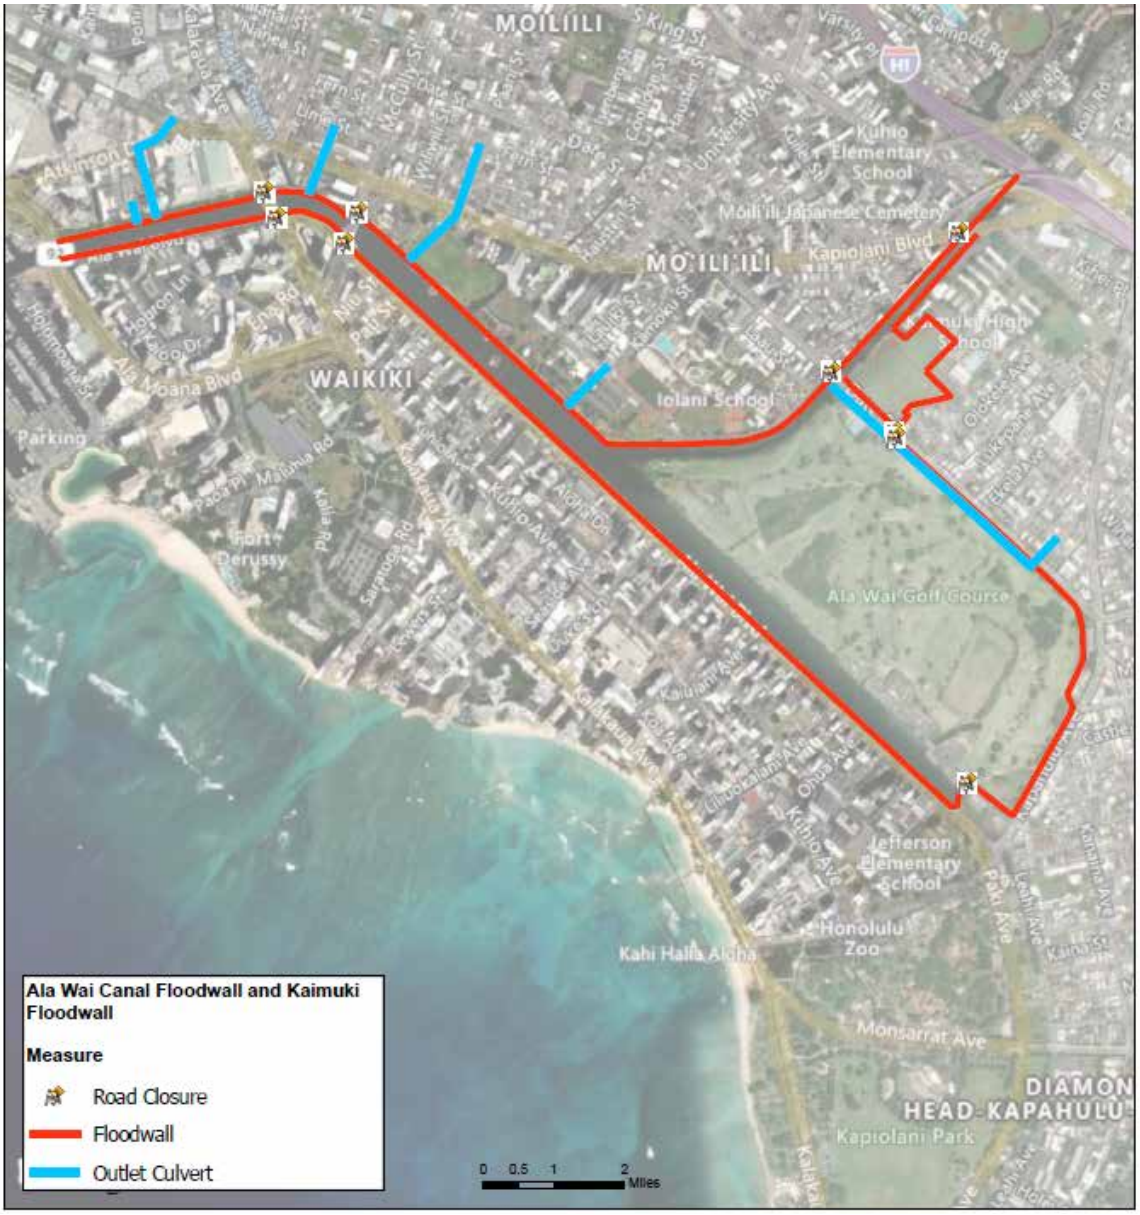

Figure 5-21 Ala Wai Canal Floodwall and Kaimuki High School Floodwall

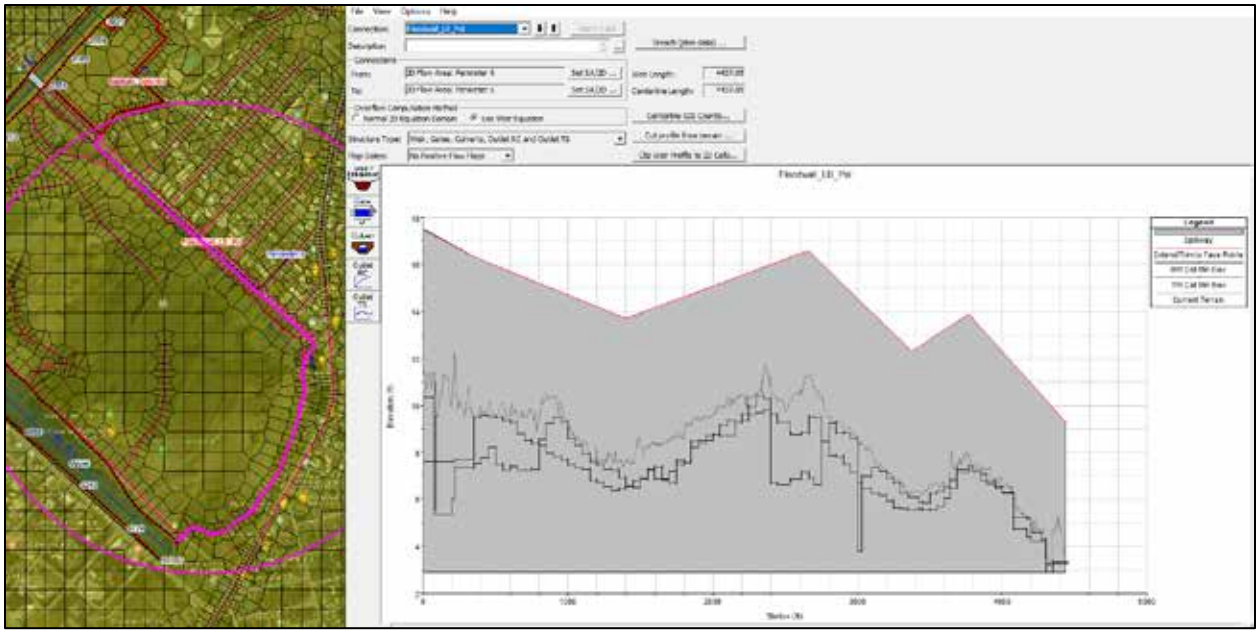

Figure 5-22: Ala Wai Golf Course Berm Profile

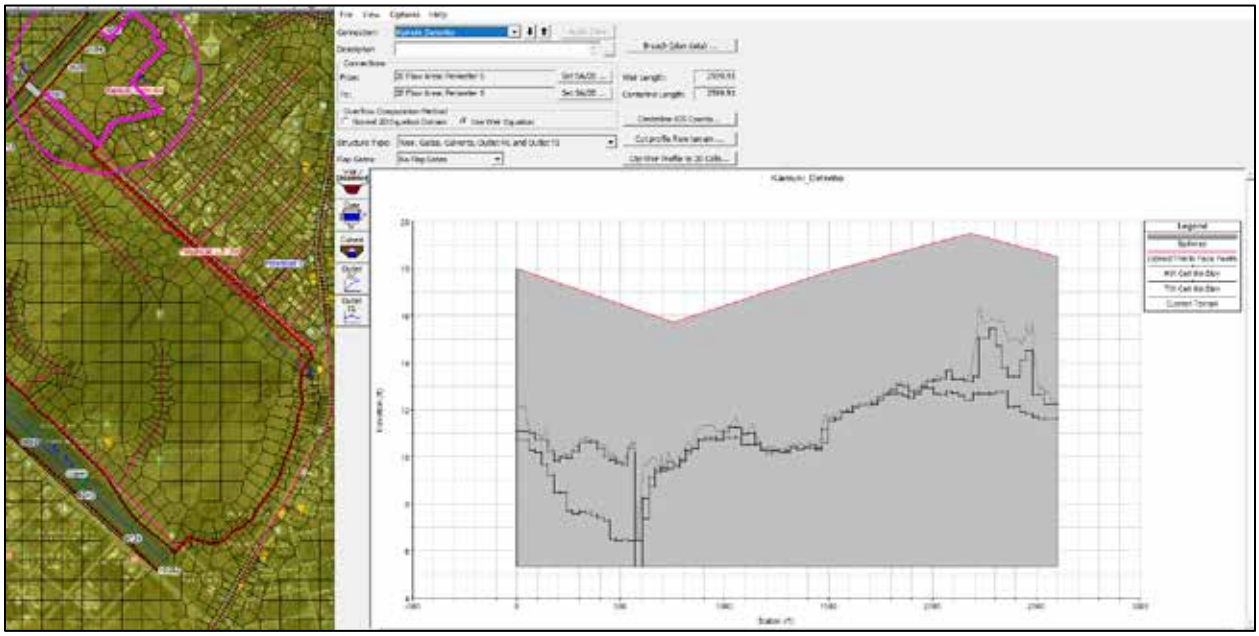

Figure 5-23: Kaimuki High School Floodwall Profile

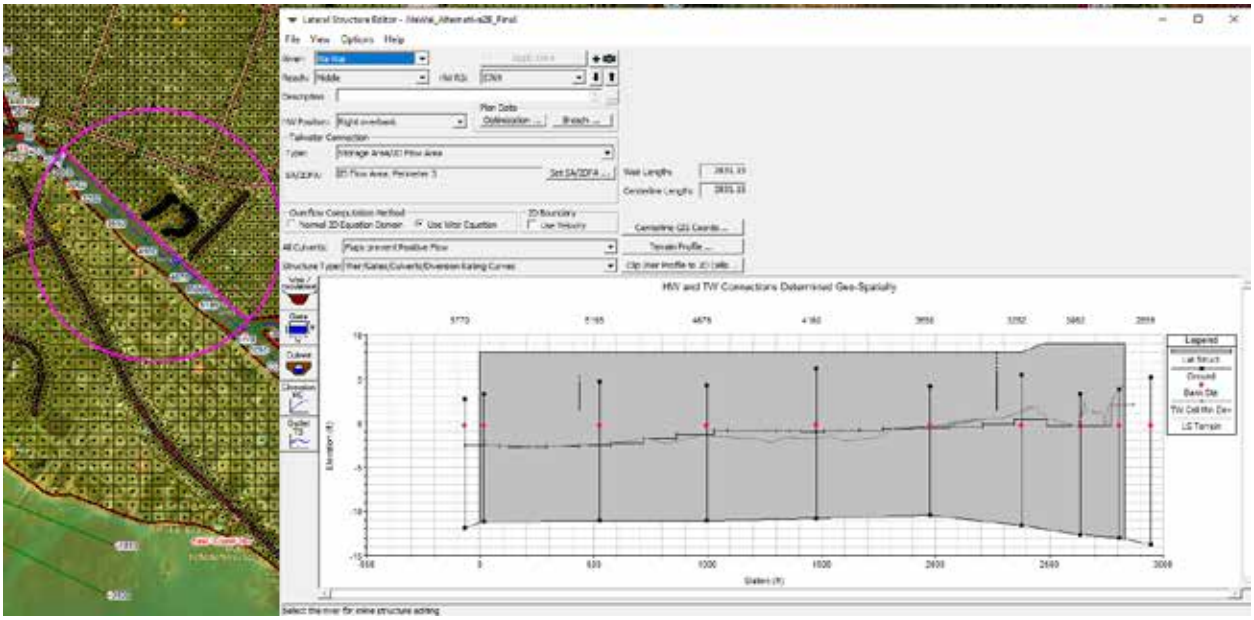

Figure 5-24: Typical Ala Wai Canal Floodwall

5.3. Alternative 5

Alternative 5 was identified as a hybrid alternative, as it utilized a combination of measures from alternatives 1 and 2B, without a specific focus placed on maximizing storage or conveyance.

5.3.1. Kanaha Floodwall and Makiki District Park Detention Area

The Kanaha Floodwall and Makiki District Park Detention Area were utilized in an identical manner here as in Alternative 1. This includes using the approximate 6ft wall heights along the Kanaha Stream as was used in Alternative 1, and not the slightly differing wall heights used in Alternative 2b. The Makiki District Park Detention Area is also unchanged from Alternative 1. Information on these measures can be found in section 5.1.1.

5.3.2. Manoa District Park Detention Area

The Manoa District Park Detention Area was utilized in an identical manner here as in Alternative 1. Information on this measure can be found in section 5.1.2

5.3.3. Woodlawn Drive Floodwall

The Woodlawn Drive Floodwall was utilized in an identical manner here as in Alternative 1. Information on this measure can be found in section 5.1.3.

5.3.4. Koali Road Floodwall

The Koali Road Floodwall was utilized in an identical manner here as in Alternative 1. Information can be found in section 5.1.4.

5.3.5. Ala Wai Canal Floodwall with Kaimuki High School Floodwall and Ala Wai Golf Course Detention Area

For Alternative 5, the Ala Wai Canal Floodwall was combined with both the Kaimuki High School Floodwall and the Ala Wai Golf Couse Detention Area. The floodwall consisted of 14 drainage structures ranging from 2-5 feet in height and width, with one large 25ft by 5ft drainage structure

included at the northeastern end of the golf course. Also included with the floodwall were 12 road close structures necessary for high-flow flood events.

The Ala Wai Golf Course was modeled in Alternative 5 using a berm surrounding the golf course to create detention storage similar to Alternative 1. However, Alternative 5 utilized an overflow section in the berm in the form of a weir to divert flow into the golf course instead of an inline structure on the Manoa-Palolo Canal. This overflow section was located just downstream of Date Street.

The Kaimuki High School Floodwall was utilized in the same manner as Alternatives 1 and 2B, except for it connected to the Ala Wai Canal Floodwall and the Ala Wai Golf Course differently. This consisted of additional drainage structures and road closure structures. The use of the Ala Wai Canal Floodwall, Kaimuki High School Floodwall, and Ala Wai Golf Course for Alternative 5 is shown below in Figure 5-25.

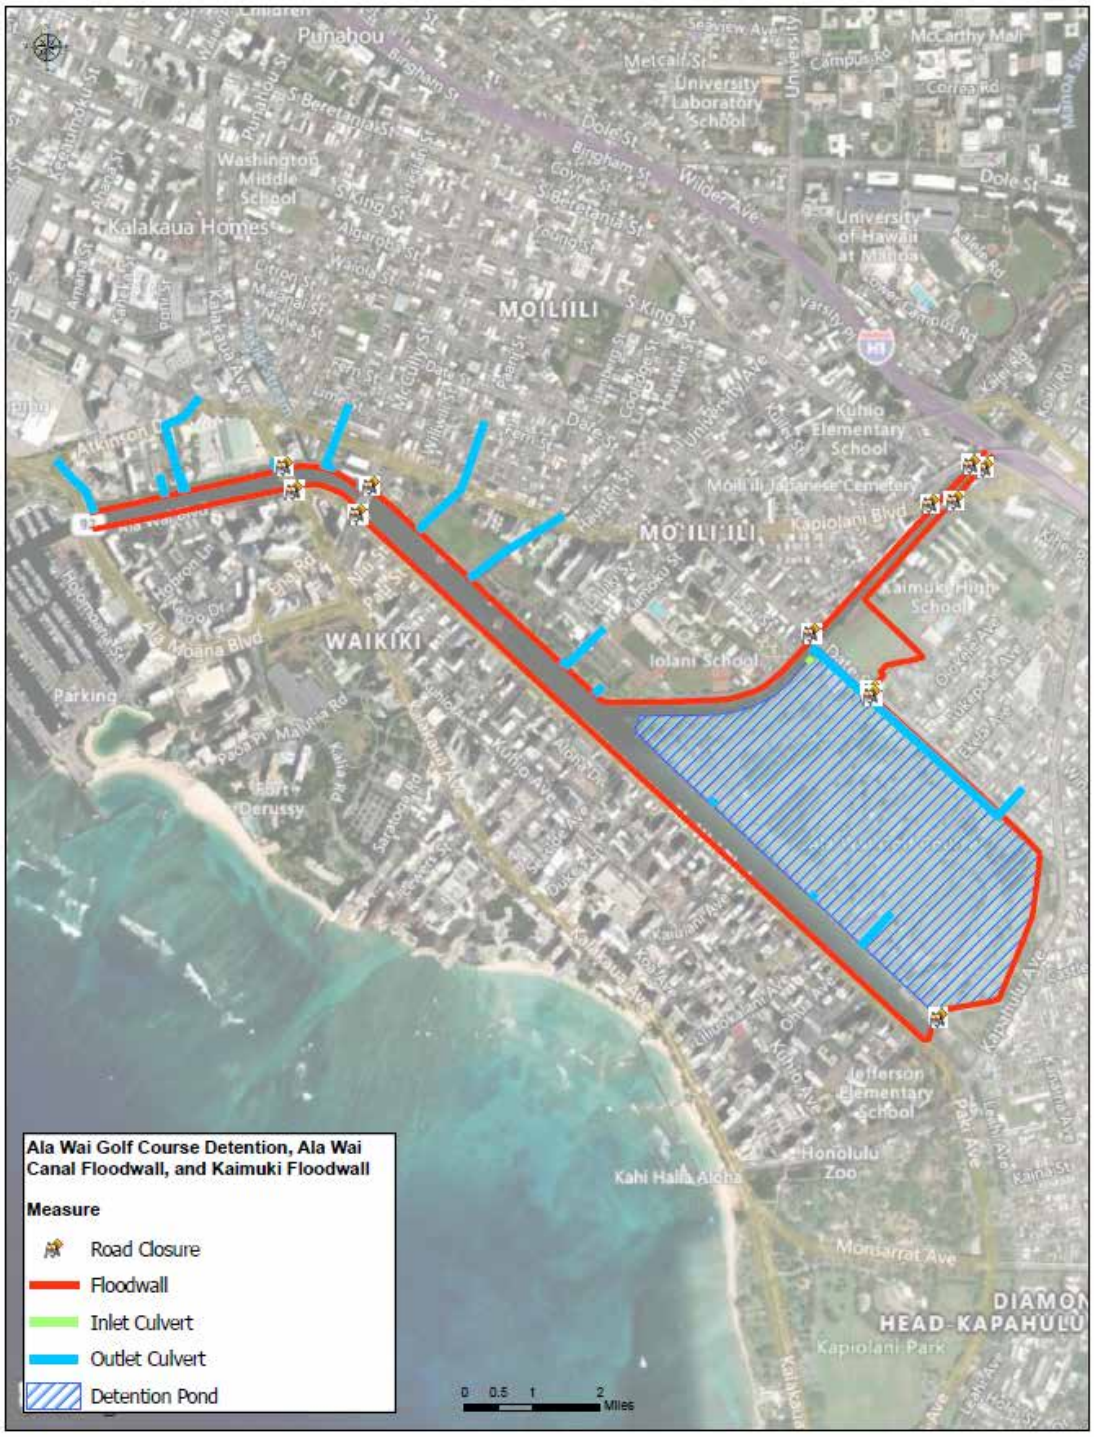

Figure 5-25 Ala Wai Canal Floodwall with Kaimuki High School Floodwall and Ala Wai Golf Course Detention Area

6. Summary of Results for Final Array of Alternatives

6.1. Alternative Comparisons

The Future Without Project model runs are compared to the Future With Project Alternatives. Table 6-4 shows the 1% AEP water surface elevations and discharge for the FWOP and all three alternatives at select locations in the Ala Wai Watershed that were used as Index Cross Sections for the Economic Analysis, shown in Figure 6-1. As the hydrologic inputs were the same for the FWOP and all alternative analyses, any changes in the discharge is due to the structural measures.

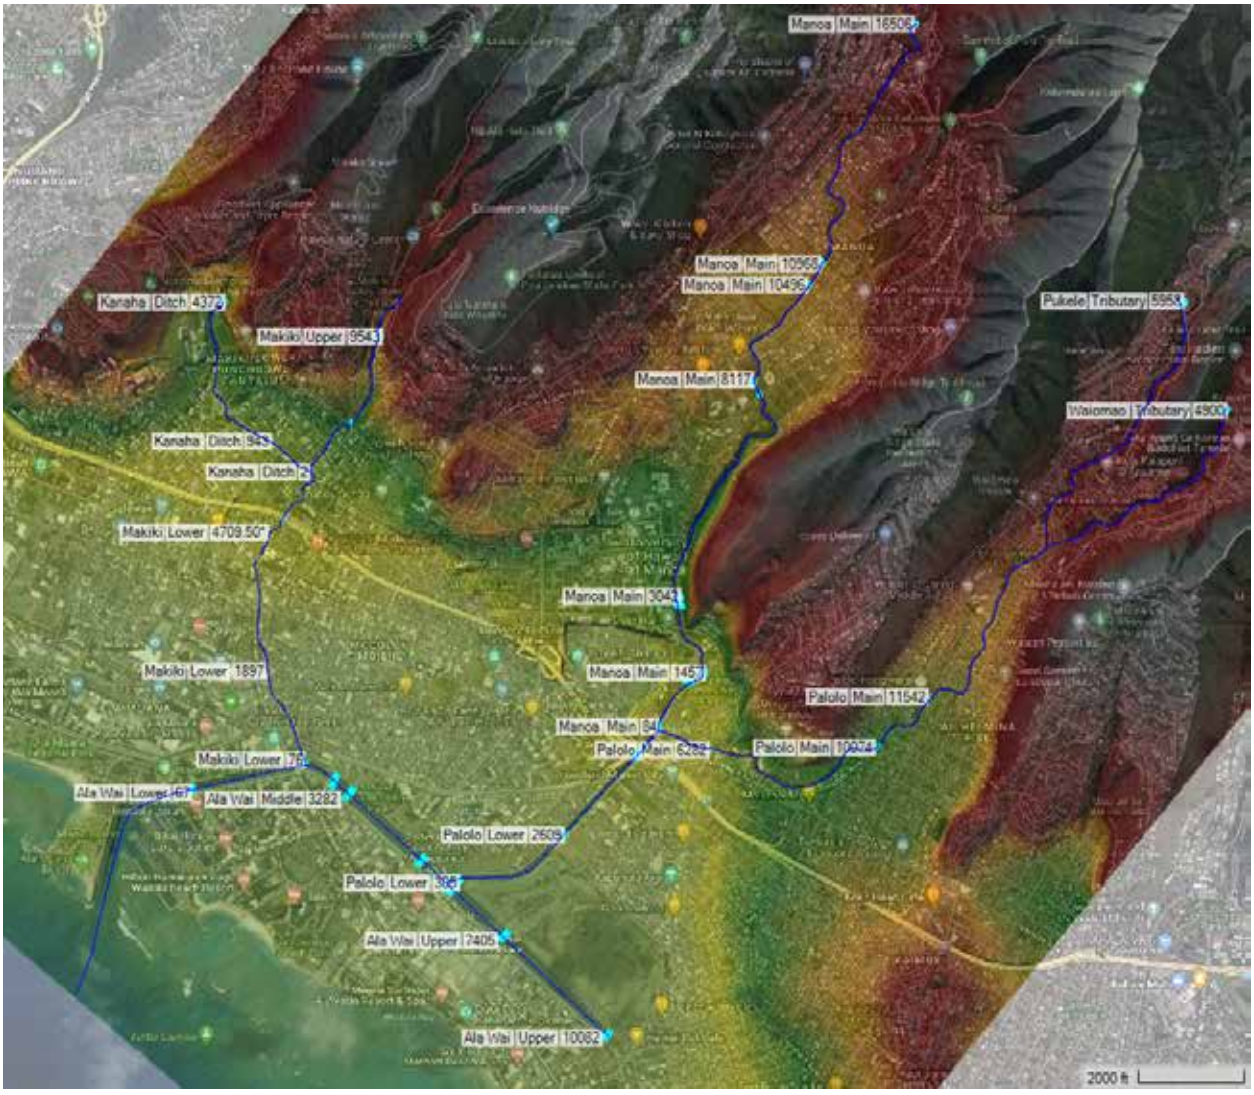

Figure 6-1: Index Cross Section Locations

6.2. Flood Inundation Maps

Flood Inundation Maps were created for the 5% AEP (20-year), the 2% AEP (50-year), and the 1% AEP (100--year) flood events for the FWOP conditions and for the three final alternatives modeled.

6.2.1. 5% AEP Flood inundation Maps

The inundation depth grids for the 5% AEP (20-year) flood event is shown below for the Future Without Project conditions, for the Future Alternative 1 conditions, the Future Alternative 2b conditions, and the Future Alternative 5 conditions in the figures below, Figure 6-1 through Figure 6-4, respectively.

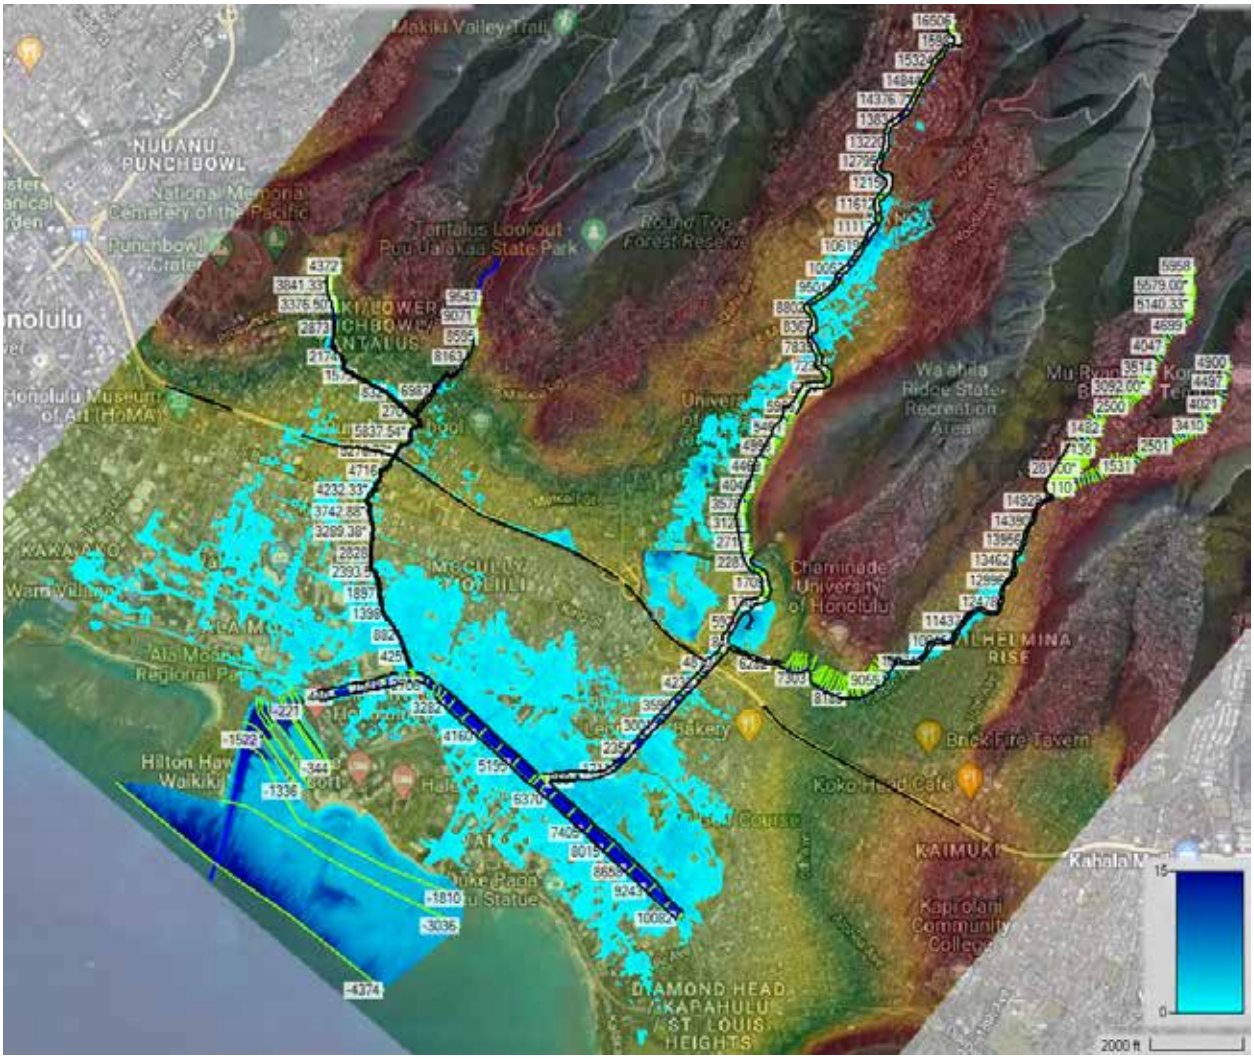

Figure 6-2: FWOP - 5% AEP (20-year) Flood Event

7. Tentatively Selected Plan Refinement

7.1. Alternative 5.1: TSP after Incremental Analysis

The PDT conducted an incremental analysis of the project features contained in Alternative 5, which was the tentatively selected plan alternative. From the incremental analysis, modifications to the alternative were made.

Summary of changes:

Removed Makiki Park detention basin.
Removed Kanaha Floodwall.
Removed Manoa Park detention basin.
Adjusted alignment to increase storage at Ala Wai Community Park and reduce storage at Kaimuki High School.
Added ringwall around Ala Wai Golf Course Club House.
Focused design of floodwall sections (J-wall, Tieback I-Wall, etc.).
Included more detail on drainage structures and flap gate locations.
Included locations of canoe access points.

The project features included in this alternative are shown in Figure 7-1 and described below.

Figure 7-1: TSP Alternative 5.1 Measures Overview

7.1.1. Woodlawn Drive Floodwall & Koali Road Floodwall

Located within Manoa Valley, this floodwall extends a maximum of 6 ft above ground level (i.e., Woodlawn Drive Floodwall) and would be constructed along the right descending bank of Manoa Stream. The floodwall would be approximately 1,270 ft in length. A single road closure structure at Woodlawn Drive would be constructed. The Woodlawn Drive Floodwall would reduce the risk of flooding to the University of Hawaii and downstream residential structures due to overtopping at Woodlawn Drive Bridge. At Koali Road, near the convergence of Manoa and Palolo streams, a floodwall extending 6 ft above ground (i.e., Koali Road floodwall) would be constructed along the left descending bank of Manoa Stream and the right descending bank of Palolo Stream. The floodwall would be approximately 2,026 ft in length. Two box culverts would be constructed to provide interior drainage of stormwater flows from the residential neighborhood behind the Koali Road floodwall, and two flap gates would be retrofitted on smaller stormwater culverts along this feature. Two road closure structures would be constructed. The purpose of the Koali Road Floodwall is to reduce risk to adjacent residential structures, including induced damages caused by the Woodlawn Drive Floodwall. Thus, the Woodlawn Drive Floodwall and Koali Road Floodwall function as a system.

7.1.2. Ala Wai Golf Course Detention Basin

At Ala Wai Golf Course, adjacent to the Manoa-Palolo Canal and the Ala Wai Canal, an earthen levee approximately 6 ft in height would be constructed around the perimeter of Ala Wai Golf Course to create a detention basin (i.e., Ala Wai Golf Course Detention Basin). The total length of the earthen levee would be approximately 10,151 ft in length and would extend along the perimeter of the Ala Wai Golf Course along the Manoa-Palolo and Ala Wai canals. Near the vicinity of the Kapahulu Avenue and Ala Wai Boulevard intersection, the levee would join with the Ala Wai Canal Floodwall on the left descending bank of Ala Wai Canal. The existing drainage ditch that runs along the north side of the golf course (parallel to Date Street) would be riprapped and used as an inlet for stormwater to overflow into the Ala Wai Golf Course Detention Basin. Four concrete drainage structures and four flap gates would be constructed along the levee alignment of the Ala Wai Golf Course to allow collected stormwater within the basin and from local runoff to slowly drain into Ala Wai Canal. The detention pond also includes a small floodwall around the Club House, which is 6 feet in height and 2,409 ft in length. The floodwall, or ringwall, has two flapgates and one road closure structure. Finally, there is one canoe access point in this location. The Ala Wai Golf Course Detention Basin would reduce the risk of flooding within the lower watershed.

7.1.3. Ala Wai Canal Floodwall

At the Manoa-Palolo Canal and Ala Wai Canal, a floodwall extending 6 ft above ground (i.e., Ala Wai Canal Floodwall) would be constructed. The floodwall would be approximately 22,796 ft long. Existing stormwater sewers inletting into the Ala Wai Canal would be modified so that

fifteen would be drainage structures and 59 would be retrofitted with flap gates. Twelve road closure structures would be constructed. There are three canoe access points for this feature. The typical cross section of this feature varies along the alignment. The floodwall along the canal, where space is not constricted, will include a walking path. Where space is constricted, Tieback I-Walls or L-walls will be constructed, with no walking path. The purpose of the Ala Wai Canal Floodwall system would be to reduce the risk of flooding within the McCully-Moiliili neighborhood, Diamond Head neighborhood, and Waikiki.

7.2. Alternative 5.2: TSP after Induced Damages Mitigation

The PDT investigated modifications to project features contained in Alternative 5.1, along with new possible project features, in order to reduce the induced damages. From the reduction of induced damages analysis, modifications to the alternative were made based on analyses of the 2% and 0.2% AEP flood events.

Summary of changes:

Added Makiki Floodwall up to Fern Street.
Adjusted alignment of floodwall at Kaimuki High School to increase storage and allow floodwaters to enter golf course over Date Street.
Included design of inflow channel onto golf course.

The project features included in this alternative are shown in Figure 7-2 and described below.

Figure 7-2: TSP Alternative 5.2 Measures Overview

7.2.1. Woodlawn Drive Floodwall & Koali Road Floodwall

There is no change to these measures from Alternative 5.1. This measure is within Manoa Valley and consists of a floodwall extending 6 ft above ground level (i.e., Woodlawn Drive Floodwall). The floodwall would be constructed along the right descending bank of Manoa Stream. The floodwall would be approximately 1,270 ft in length. A single road closure structure at Woodlawn Drive would be constructed. The Woodlawn Drive Floodwall would reduce the risk of flooding to the University of Hawaii and downstream residential structures due to overtopping at Woodlawn Drive Bridge. At Koali Road, near the convergence of Manoa and Palolo streams, a floodwall extending 6 ft above ground (i.e., Koali Road floodwall) would be constructed along the left descending bank of Manoa Stream and the right descending bank of Palolo Stream. The floodwall would be approximately 2,510 ft in length. Two concrete drainage structures would be constructed to provide interior drainage of stormwater flows from the residential neighborhood behind the Koali Road floodwall. Two flap gates would be retrofitted on smaller stormwater culverts along this feature. Two road closure structures would be constructed. The purpose of the Koali Road Floodwall is to reduce risk to adjacent residential structures, including induced damages caused by the Woodlawn Drive Floodwall. Thus, the Woodlawn Drive Floodwall and Koali Road Floodwall function as a system.

7.2.2. Ala Wai Golf Course Detention Basin

At Ala Wai Golf Course, adjacent to the Manoa-Palolo Canal and the Ala Wai Canal, an earthen levee approximately 6 ft in height would be constructed around the perimeter of Ala Wai Golf Course to create a detention basin (i.e., Ala Wai Golf Course Detention Basin). The total length of the earthen levee would be approximately 10,151 ft in length and would extend along the perimeter of the Ala Wai Golf Course along the Manoa-Palolo and Ala Wai canals. On the left descending bank of the Manoa-Palolo Canal, there is an overtopping spillway section, approximately 100 feet in length, that is reinforced with erosion protection. The levee along the Manoa-Palolo Canal is also lined with erosion protection on the canal-side. A portion of the existing drainage ditch that runs along the north side of the golf course (parallel to Date Street) would be used as an inlet location for overflow into the Ala Wai Golf Course Detention Basin. A small inlet channel would be excavated and lined with erosion control material to improve the flow onto the golf course. Four concrete drainage structures and three flap gates would be constructed along the levee alignment of the Ala Wai Golf Course to allow collected stormwater within the basin and from local runoff to slowly drain into Ala Wai Canal.

The detention basin also includes a small floodwall (ringwall) around the Club House, which is 6 feet in height and 1,206 ft in length. The floodwall has two flap gates and one road closure structure. A small section of floodwall near the Kapahulu Avenue and Ala Wai Boulevard intersection at the Diamond Head end of the canal will tie-in to the golf course levee and Ala Wai Canal floodwall system. This section is 6 feet in height and includes one road closure structure and one drainage structure. Finally, there is one canoe access point in this location. The Ala Wai Golf Course Detention Basin would reduce the risk of flooding within the lower watershed. See Figure 7-2 below for the revised alignments.

Figure 7-3: TSP Alternative 5.2 Alignments of the Ala Wai Golf Course Detention, Ala Wai Floodwall, and Makiki Floodwall

7.2.3. Ala Wai Canal Floodwall

At the Manoa-Palolo Canal and Ala Wai Canal, a floodwall extending 6 ft above ground (i.e., Ala Wai Canal Floodwall) would be constructed. The floodwall would be approximately 23,708 ft long. Existing stormwater sewers inletting into the Ala Wai Canal would be modified so that fourteen would be drainage structures and 59 would be retrofitted with flap gates. Eleven road closure structures would be constructed. There are three canoe access points for this feature. The typical cross section of this feature varies along the alignment but all are assumed to be 6 feet above ground. The floodwall along the Ala Wai Canal and the lower right descending bank of the Manoa-Palolo Canal will include an elevated walking path. On the left descending bank of the Manoa-Palolo Canal and near Kaimuki High School, there will be a floodwall on macropiles with no walking path. Where space is constricted, along the upper right descending bank of the Manoa-Palolo Canal, Tieback I-Walls (tied-back I-wall) will be constructed, with no walking path. The purpose of the Ala Wai Canal Floodwall system would be to reduce the risk of flooding

within the McCully-Moiliili neighborhood, Diamond Head neighborhood, and Waikiki. See Figure 7-2 above for the revised alignments.

7.2.4. Makiki Stream Floodwall

To mitigate risk due to the increased storage of water in the Ala Wai Canal and its backwater up Makiki Stream, a floodwall will be included from the confluence with the Canal to Fern Street. This is a concrete-lined U-Wall that will extend 6 feet above ground on both sides of the stream. There is a potential to add a low-flow channel cut for environmental considerations. Total length of the U-wall is approximately 883 linear feet. The floodwall will include two flap gates, one concrete drainage structure, and four road closure structures, of which two are small pedestrian bridge closures. The Ala Wai Canal Floodwalls and Makiki Stream Floodwalls function as a system. See Figure 7-2 above for the alignment and and Figure 7-3 below for a typical cross section of the U-Shape floodwall for the Makiki Stream.

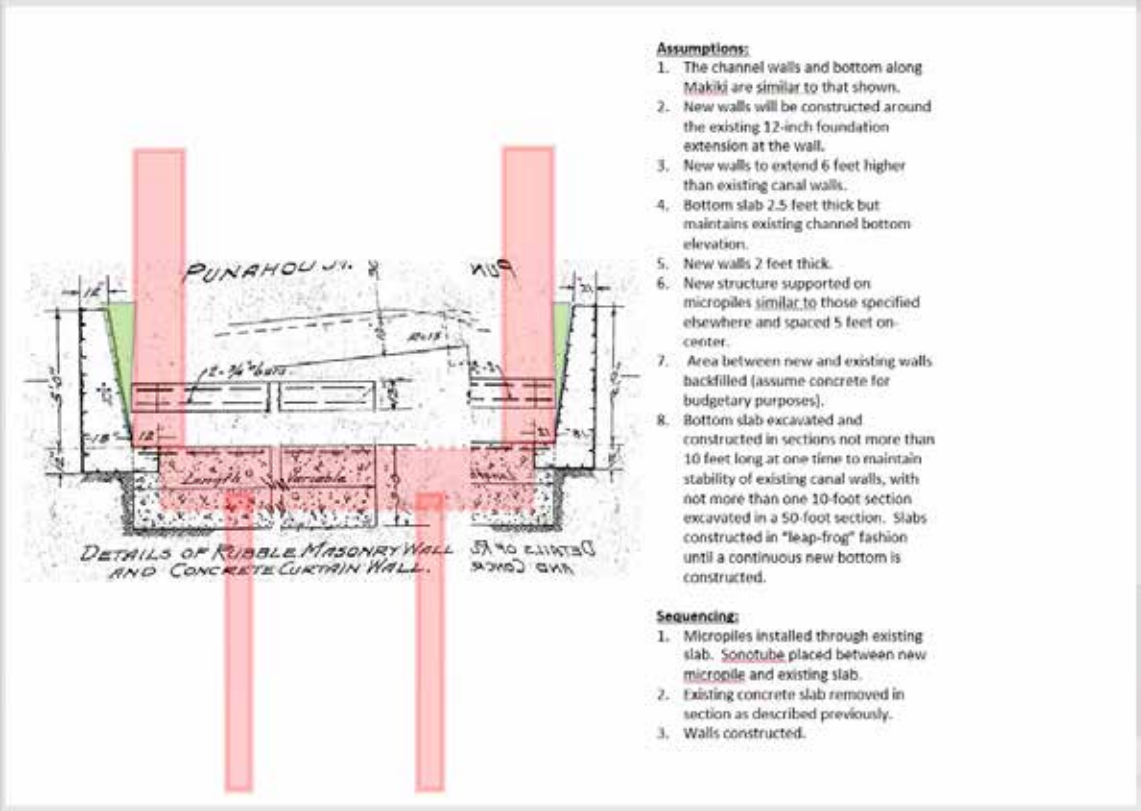

Figure 7-4: U-Shape floodwall ("U-wall") along Makiki Stream.

7.3. Alternative 5.3 - TSP - Recommended Plan

After the economic analysis was completed on Alternative 5.2, it was determined that the induced damages for the higher less frequent flood events analyzed had significant reduced damages, but the lower more frequent flood events actually saw an increased induced damages to the 50% and 20% AEP flood events due to the Makiki Floodwall and the revised alignment along the Ala Wai Canal. Further investigation was conducted looking into the full range of flood events, from the 50% AEP up to the 0.2% AEP floods. Multiple changes were made for Alternative 5.3 to further reduce the induced damages. A summary of changes and a list of final project features are listed below and can be seen in Figure 7-5. See Figure 7-6 below for a map of the Alternative 5.3 project features.

Summary of changes:

Removed Makiki Floodwall up to Fern Street
Adjusted alignment of floodwall at Kaimuki High School to increase storage and allow floodwaters to enter golf course over Date Street
Removed the ring wall at the Ala Wai golf course and increased the levee height to 9 ft for increased storage.

Summary of measures in the recommended plan:

Woodlawn Drive Floodwall
Koali Road Floodwall
Ala Wai Golf Course Detention
Ala Wai Floodwall

Figure 7-5: Conceptual Diagram of Changes from Alternative 5.2 to Alternative 5.3

Figure 7-6: Alternative 5.3, the Recommended Plan, Measures Overview

7.3.1. Woodlawn Drive Floodwall & Koali Road Floodwall

There is no change to these measures from Alternative 5.1 or Alternative 5.2. The Woodland Drive Floodwall is located within Manoa Valley, and extends 6 ft above ground level (i.e., Woodlawn Drive Floodwall) and would be constructed along the right descending bank of Manoa Stream. The floodwall would be approximately 1,270 ft in length. A single road closure structure at Woodlawn Drive would be constructed. The Woodlawn Drive Floodwall would reduce the risk of flooding to the University of Hawaii and downstream residential structures due to overtopping at Woodlawn Drive Bridge. Figure 7-7 shows the Woodlawn Drive floodwall profile, and Figure 7-8 shows the alignment of the floodwall.

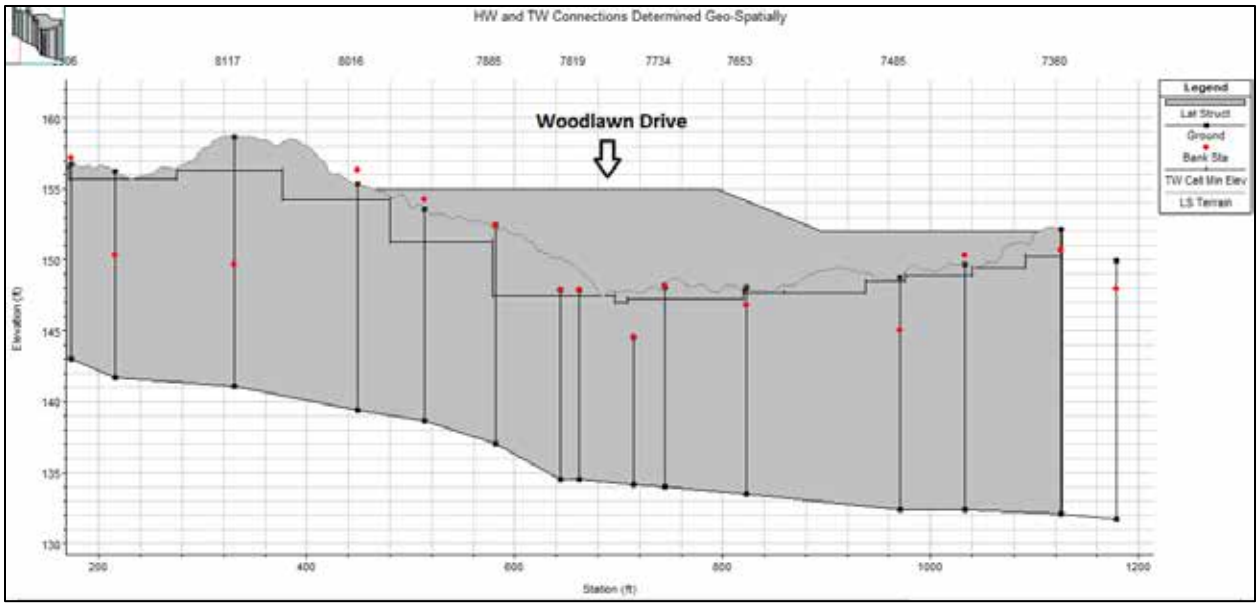

Figure 7-7: Alternative 5.3 Woodlawn Drive Floodwall Profile

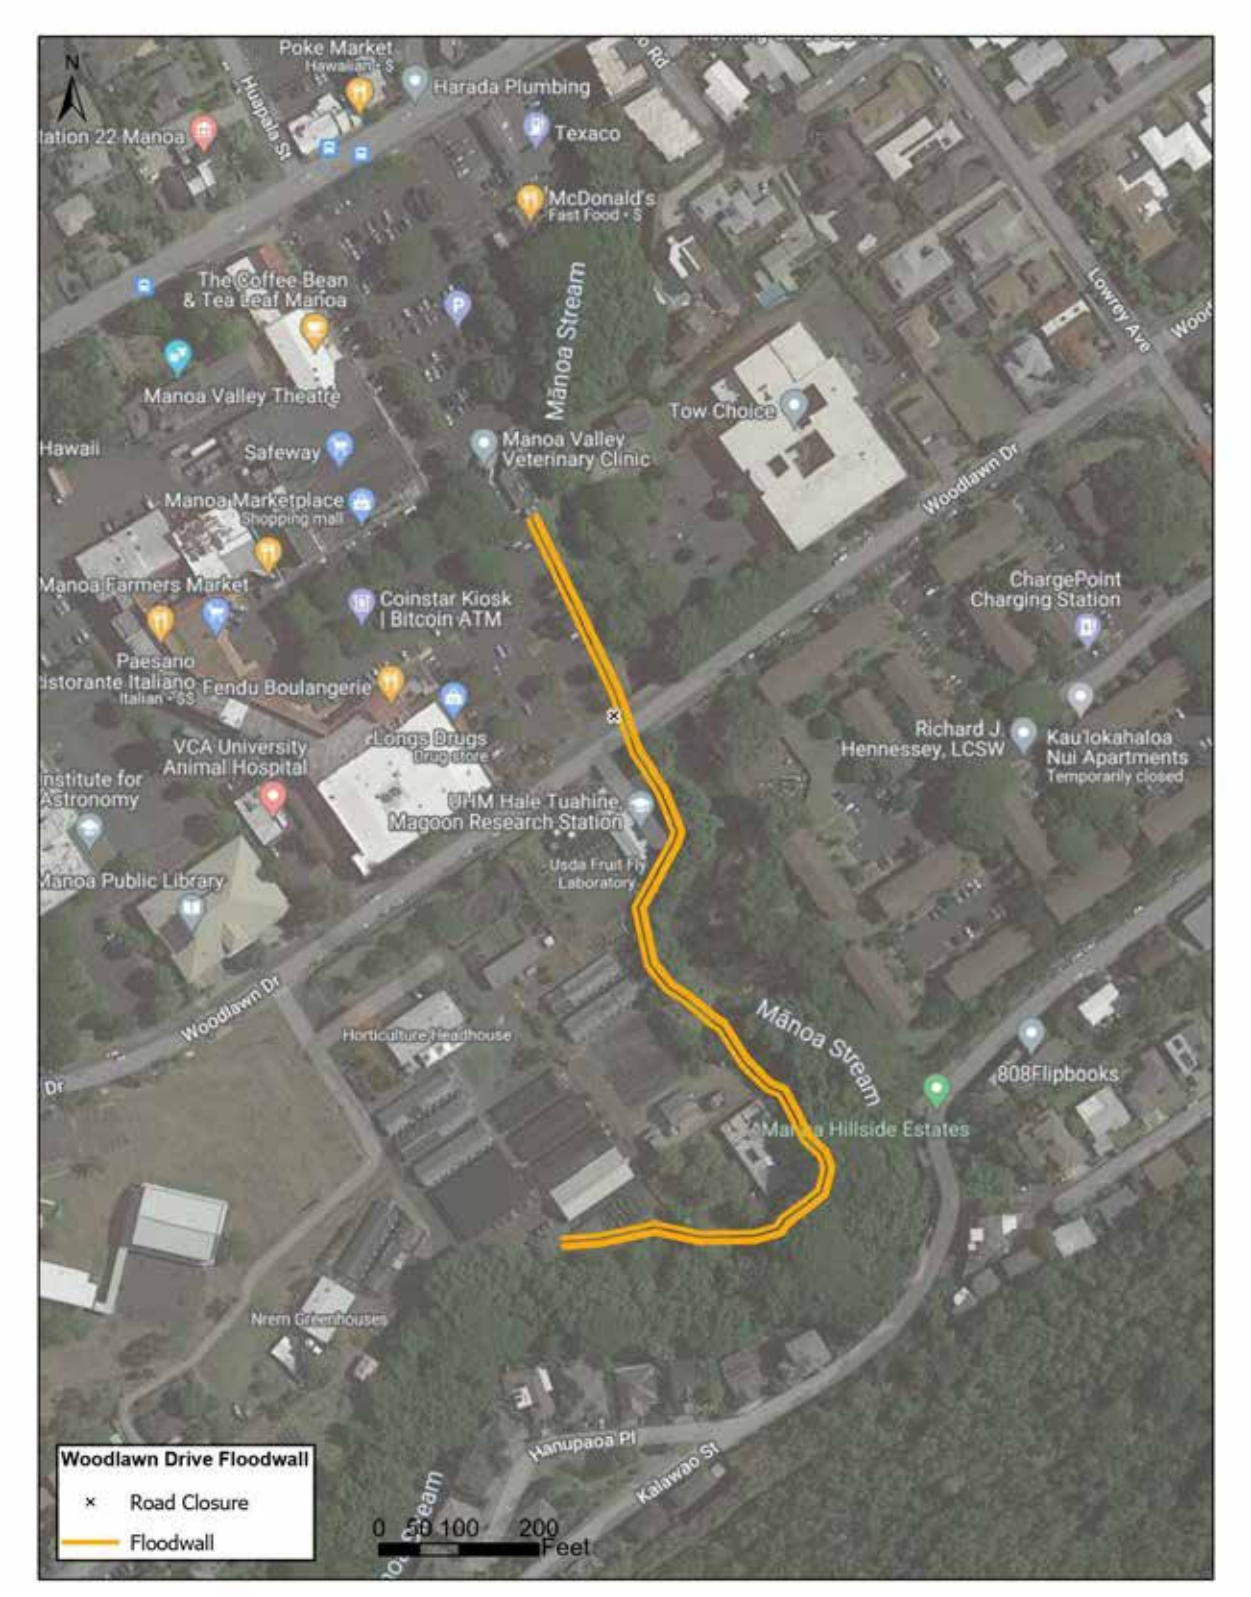

Figure 7-8: Alternative 5.3 Woodlawn Drive Floodwall

At Koali Road, near the convergence of Manoa and Palolo streams, a floodwall extending 6 ft above ground (i.e., Koali Road floodwall) would be constructed along the left descending bank of Manoa Stream and the right descending bank of Palolo Stream. The floodwall would be approximately 2,510 ft in length. Two concrete drainage structures would be constructed to provide interior drainage of stormwater flows from the residential neighborhood behind the Koali Road floodwall. Two flap gates would be retrofitted on smaller stormwater culverts along this feature. Two road closure structures would be constructed. The purpose of the Koali Road Floodwall is to reduce risk to adjacent residential structures, including induced damages caused by the Woodlawn Drive Floodwall. Thus, the Woodlawn Drive Floodwall and Koali Road Floodwall function as a system. Figure 7-9 and Figure 7-10 shows Koali Road floodwall along the Manoa Stream, and Figure 7-11 shows the Koali Road profile along the Palolo Stream. Figure 7-12 shows the alignment of the floodwall.

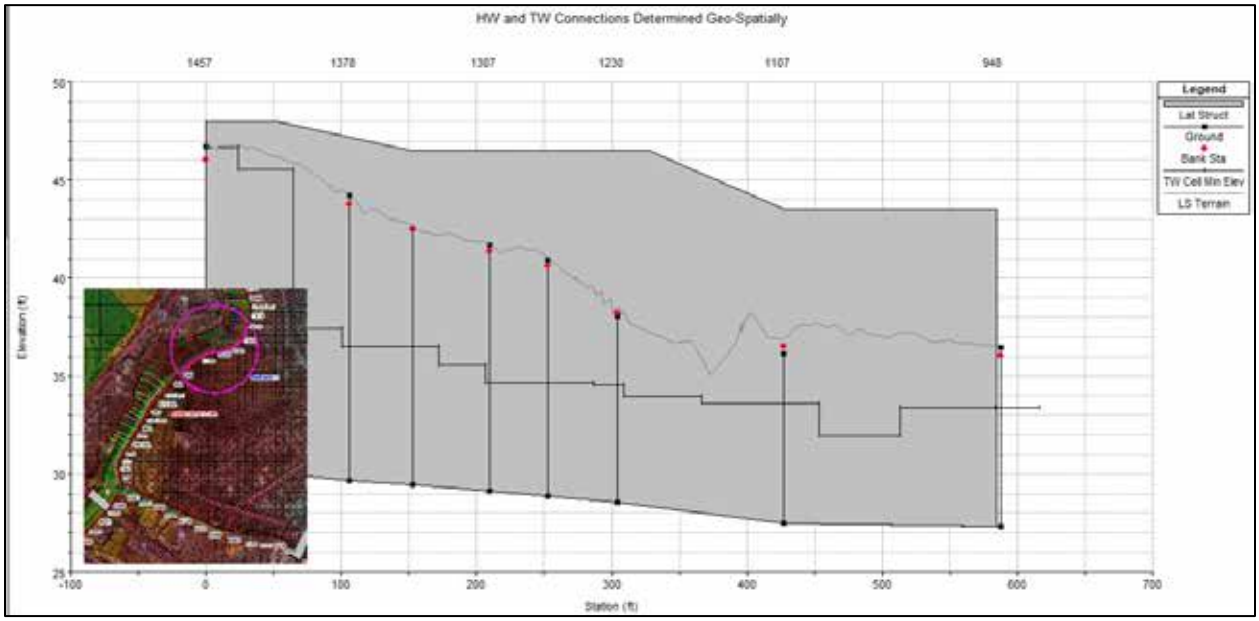

Figure 7-9: Alternative 5.3 Koali Road Floodwall Upper Profile on Manoa Stream

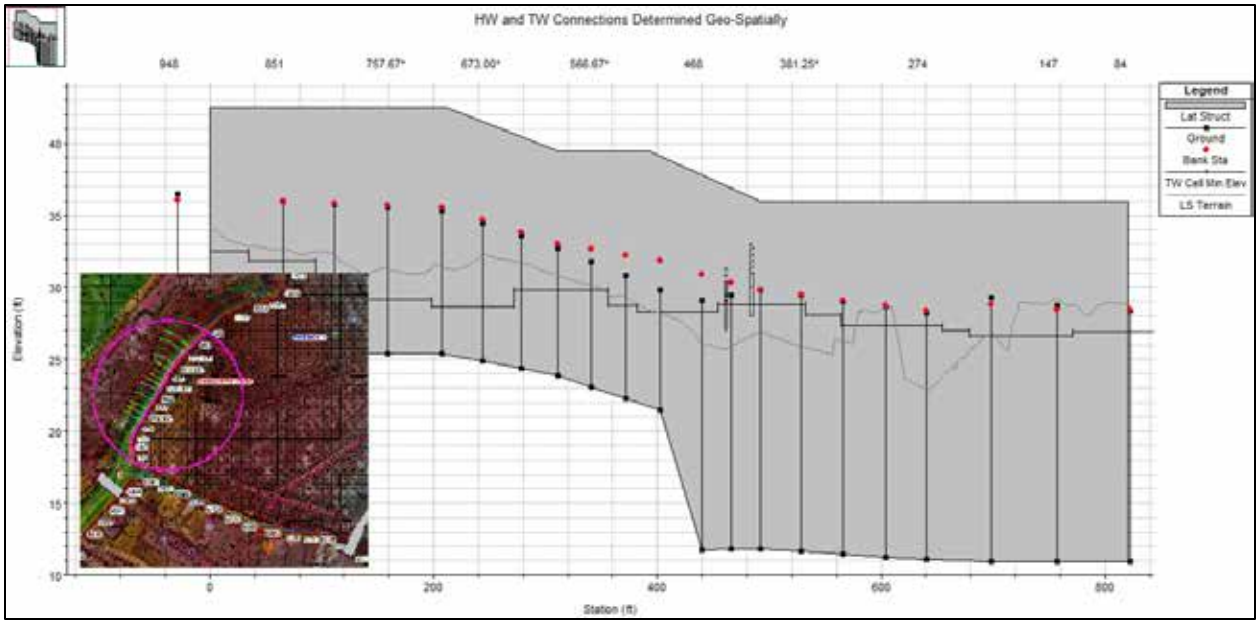

Figure 7-10: Alternative 5.3 Koali Road Floodwall Lower Profile on Manoa Stream

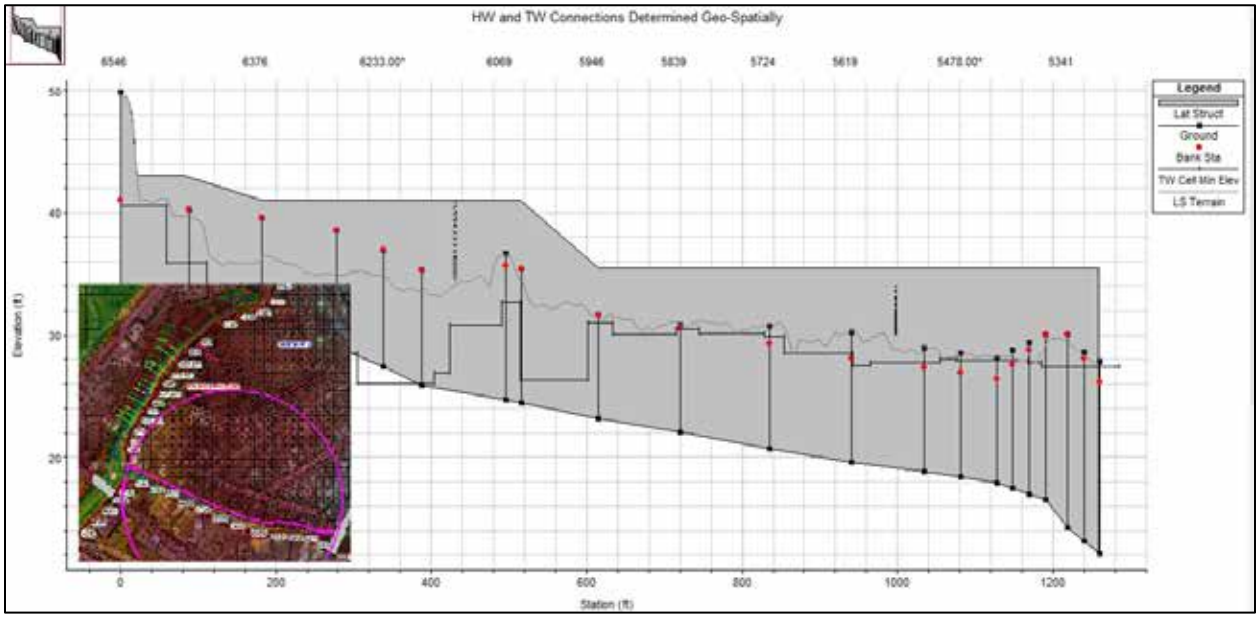

Figure 7-11: Alternative 5.3 Koali Road Floodwall Profile on Palolo Stream

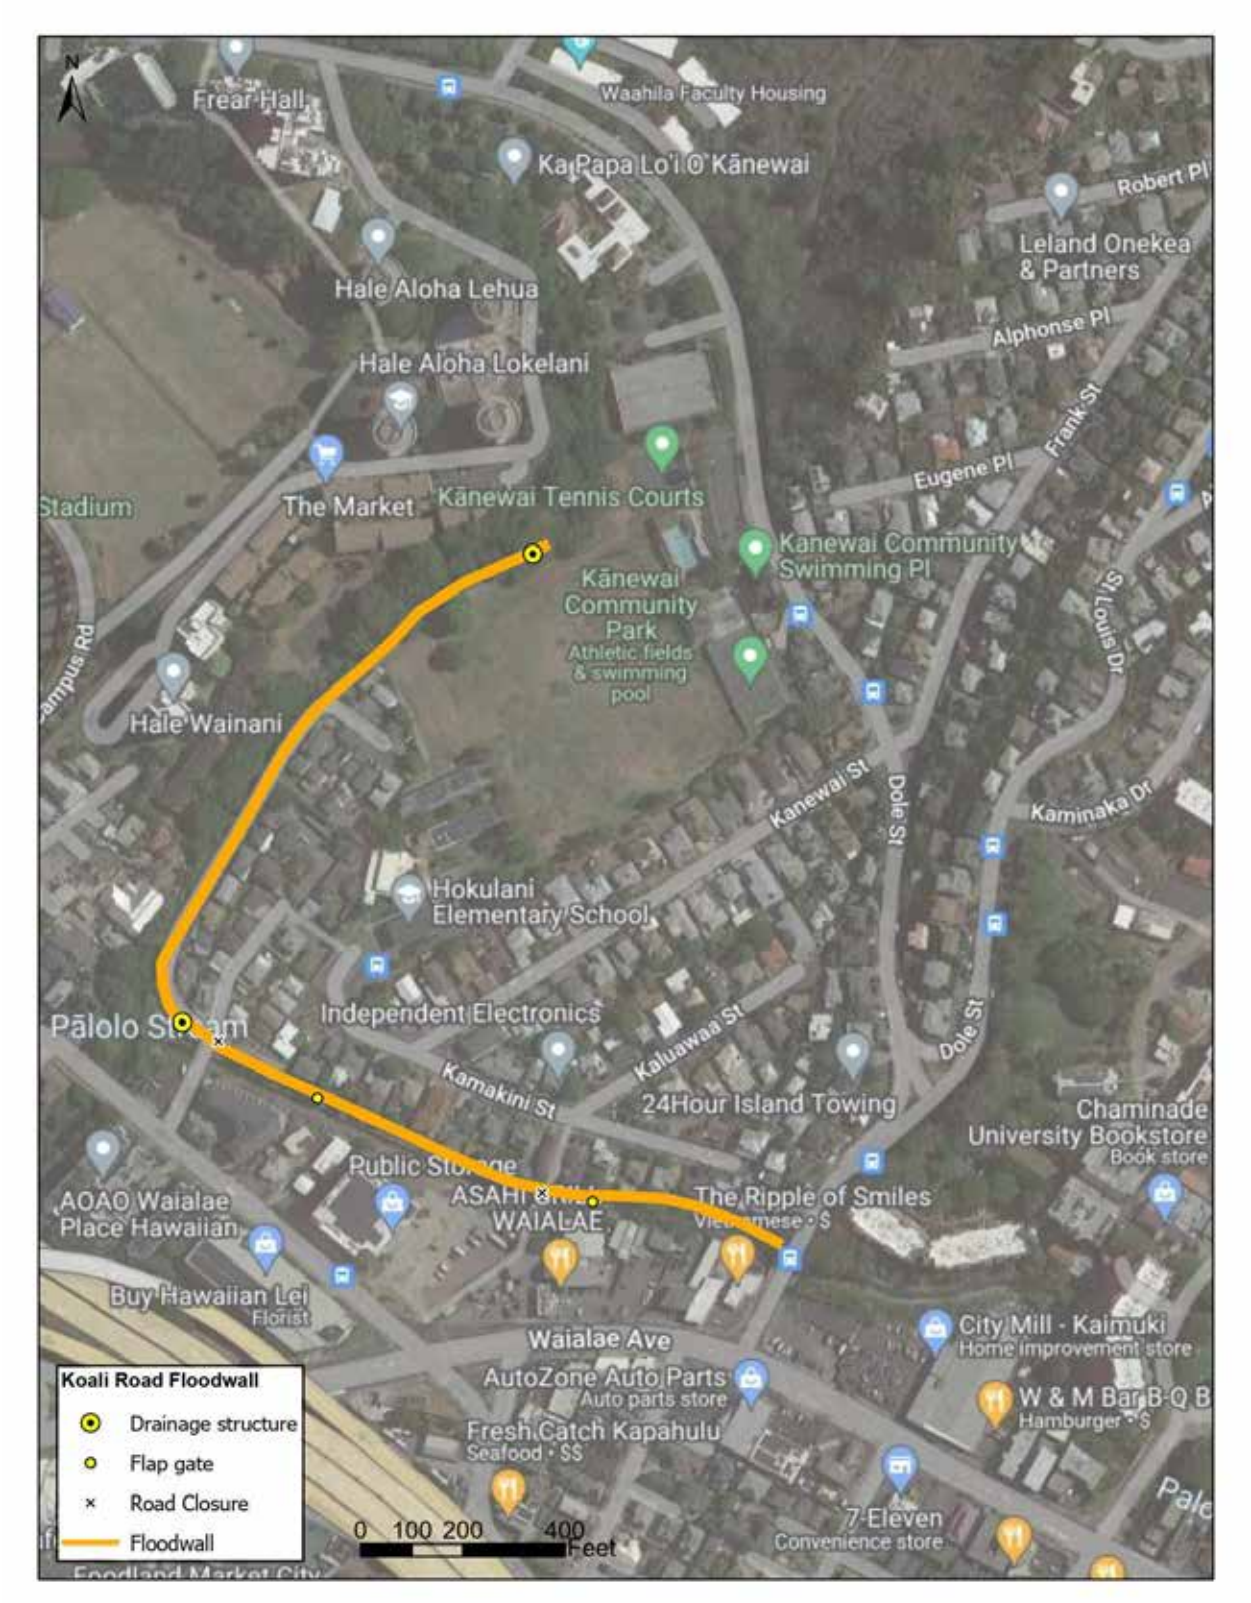

Figure 7-12: Alternative 5.3 Koali Road Floodwall

7.3.2. Ala Wai Golf Course Detention Basin

The Ala Wai Golf Course detention basin is located at the Ala Wai Golf Course, adjacent to the Manoa-Palolo Canal and the Ala Wai Canal. See Figure 7-13 below for the Golf Course Detention features. An earthen levee approximately 6-9 ft in height would be constructed around the perimeter of Ala Wai Golf Course to create a detention basin (i.e., Ala Wai Golf Course Detention Basin) to an elevation of 12 ft msl on the westward and southern sides of the Golf Course, and higher on the northern and eastern sides The total length of the earthen levee would be approximately 8,315 ft in length and would extend along the perimeter of the Ala Wai Golf Course along the Manoa-Palolo and Ala Wai canals and the northern and eastern boundaries of the Golf Course. See Figure 7-14 for the profile along the left bank of the Manoa-Palolo Canal and the right bank of the Ala Wai Canal, Figure 7-15 for the profile along the northern and eastern boundaries of the Golf Course, and Figure 7-16 for the profile of the floodwall along the left bank of the Manoa-Palolo Canal, including the area at Kaimuki High School, which is part of this measure.

The detention basin does not have any excavation due to the high-water table. The detention basin is comprised of levees and floodwalls to create storage. Currently there are no pumps, as it utilizes gravity flow to allow water onto the golf course during a storm as well as drain out to the canal after a storm.

On the left descending bank of the Manoa-Palolo Canal, there is an overtopping spillway section, approximately 100 feet in length, that is reinforced with erosion protection. The levee along the Manoa-Palolo Canal is also lined with erosion protection on the canal-side. A portion of the existing drainage ditch that runs along the north side of the golf course (parallel to Date Street) would be used as an inlet location for overflow into the Ala Wai Golf Course Detention Basin. A small inlet channel would be excavated and lined with erosion control material to improve the flow onto the golf course. Additionally, Kaimuki High School storage area impacts the Golf Course Detention by allowing water to flow into the Golf Course Detention from that area over Date Street. Both the spillway section and the inlet channel are at elevation 7.7 ft MSL. For the spillway section, this is still approximately a 3 ft high levee. Water starts entering the golf course at the 5-yr event. Not every event utilizes full capacity of the golf course detention area. The 500-yr event is not contained within the detention area, it does slightly overtop. Three concrete drainage structures and three flap gates would be constructed along the levee alignment of the Ala Wai Golf Course to allow collected stormwater within the basin and from local runoff to slowly drain into Ala Wai Canal.

The detention basin also includes a floodwall, approximately 9 ft in height and 1,621 ft in length, along the golf course parking lot near the Ala Wai Canal. The floodwall has one concrete drainage structure and two flap gates. The drainage structure at this location serves to outlet flow from the Diamond Head neighborhood. The original outlet will be enclosed by concrete (instead of daylighted) and will need reconstruction of the vehicle and pedestrian access at this location. A small section of floodwall (approximately 240 ft in length) near the Kapahulu Avenue and Ala Wai Boulevard intersection at the Diamond Head end of the canal will tie-in to the golf course levee and Ala Wai Canal floodwall system. This section is 6 feet in height and includes

one road closure structure and one drainage structure. Finally, there is one canoe access point in this location. The Ala Wai Golf Course Detention Basin would reduce the risk of flooding within the lower watershed.

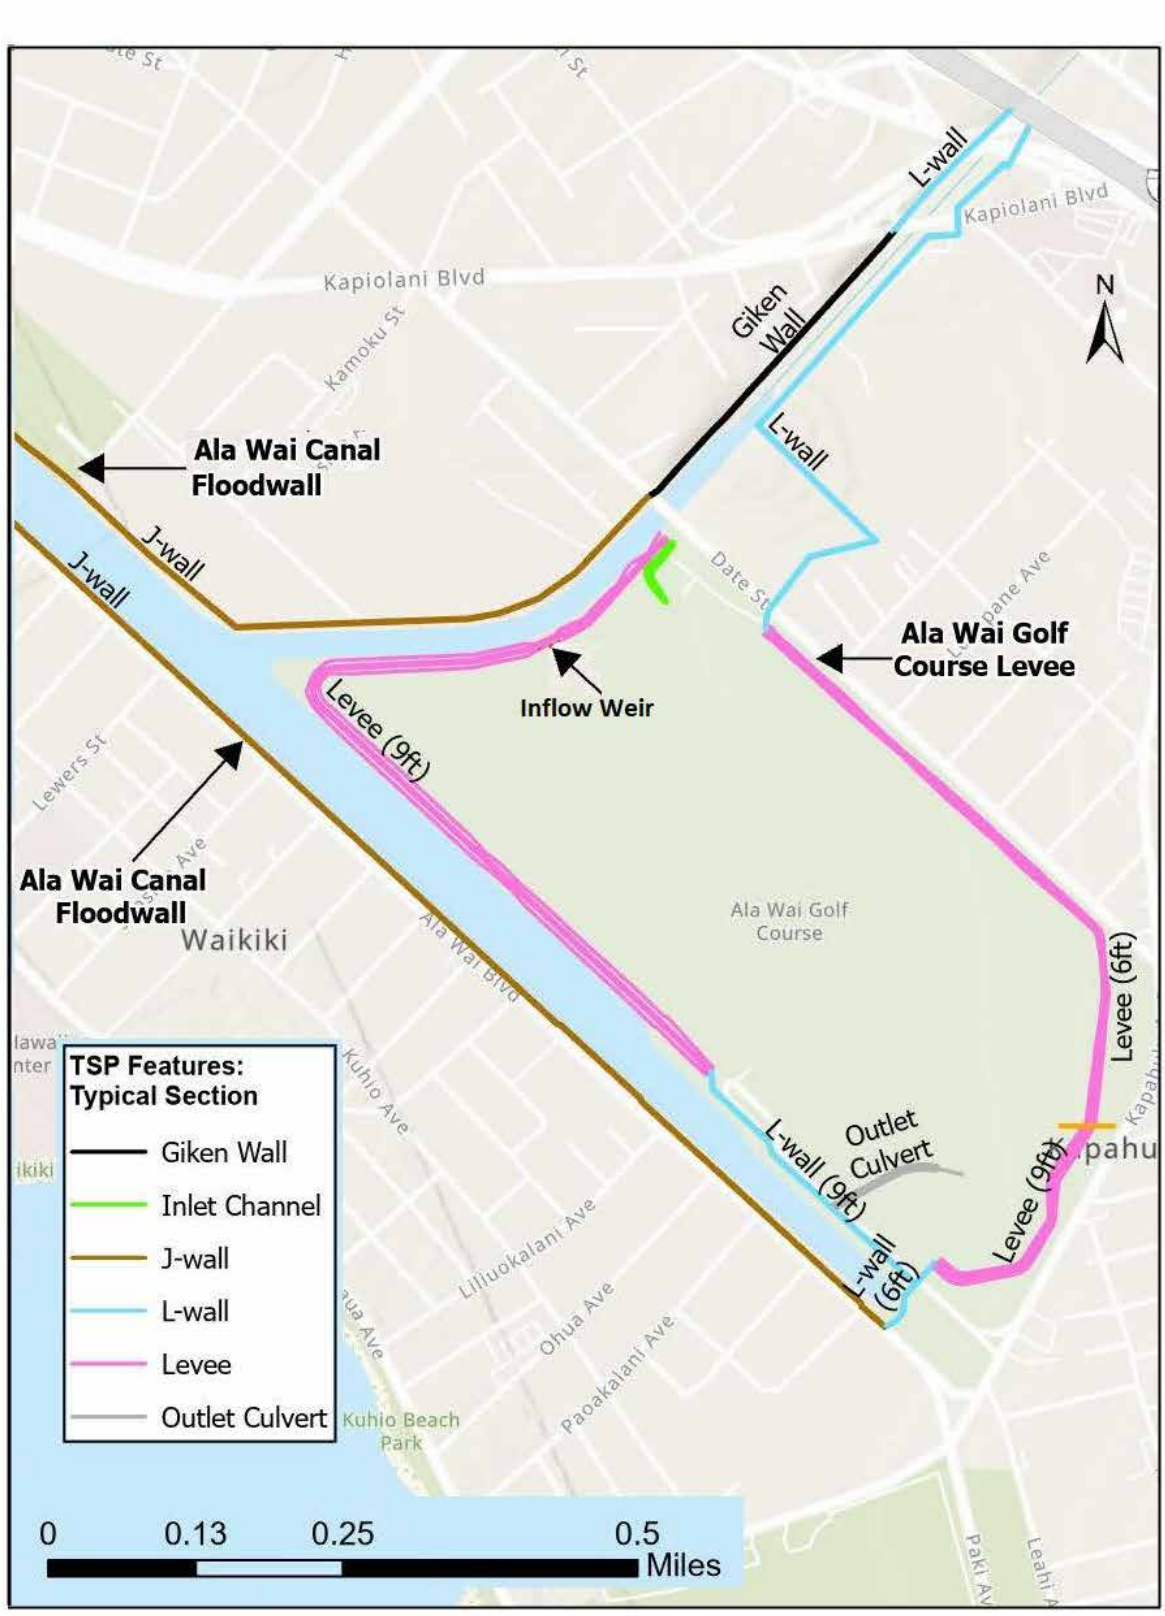

Figure 7-13: Alternative 5.3 Ala Wai Golf Course Detention

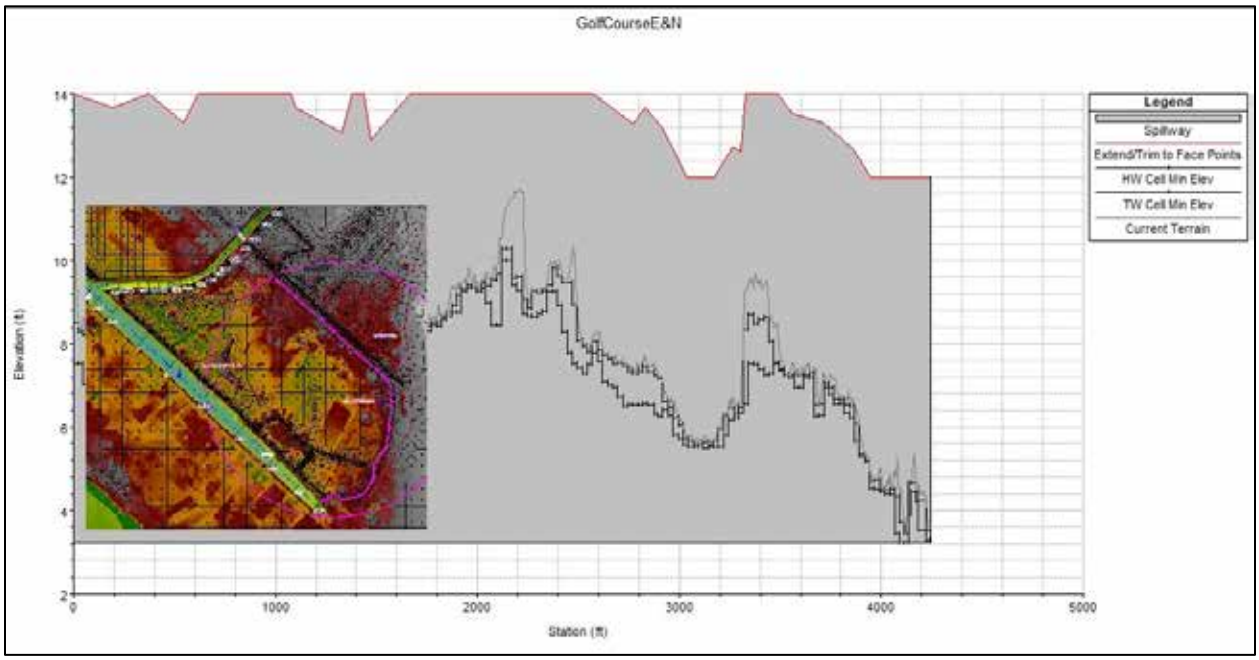

Figure 7-15: Ala Wai Course Detention Profile Along the Northern and Eastern Boundaries

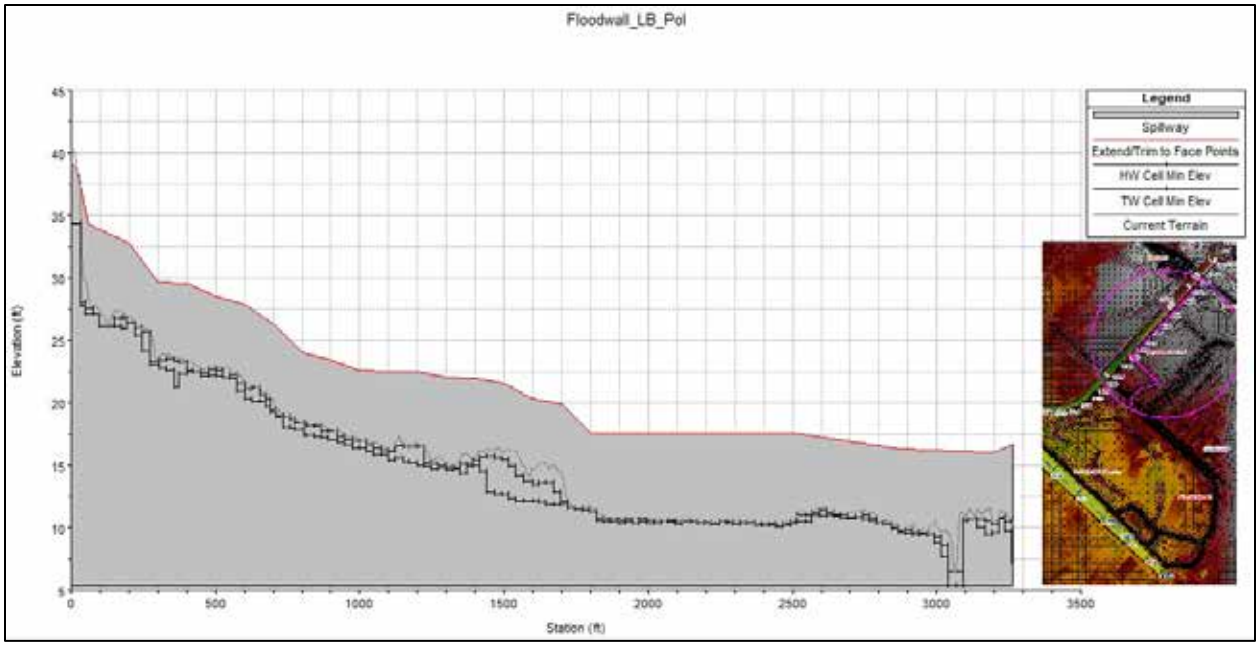

Figure 7-16: Ala Wai Canal Floodwall Along the Left Bank of the Manoa-Palolo Canal and the Kaimuki High School Floodwall (which is connected to the Ala Wai Golf Course Detention

7.3.3. Ala Wai Canal Floodwall

At the Manoa-Palolo Canal and Ala Wai Canal, a floodwall extending 6 ft above ground (i.e., Ala Wai Canal Floodwall) would be constructed. The purpose of the Ala Wai Canal Floodwall system would be to reduce the risk of flooding within the McCully-Moiliili neighborhood, Diamond Head neighborhood, and Waikiki. See Figure 7-8 for the Ala Wai Canal Floodway system alignment.

The floodwall would be approximately 22,852 ft long. Existing stormwater sewers inletting into the Ala Wai Canal would be modified so that fourteen would be drainage structures and 59 would be retrofitted with no-negative flap gates and provides drainage during favorable conditions. Simulations indicate no pumps are needed. These areas are not flooded by direct rainfall any more than the without-project plan. This does not mean that flooding is eliminated, though.

Eleven road closure structures would be constructed. There are three canoe access points for this feature. The typical cross section of this feature varies along the alignment, but all are assumed to be 6 feet above ground. The floodwall along the Ala Wai Canal and the lower right descending bank of the Manoa-Palolo Canal will include an elevated walking path. See Figure 7-18 for the profile of the right bank floodwall from the H-1 to Date Street and Figure 7-19 for the profile of the right bank floodwall from Date Street to the Ala Wai Canal Confluence. On the left descending bank of the Manoa-Palolo Canal and near Kaimuki High School, there will be a

floodwall on macropiles with no walking path, see Figure 7-16 above for the profile of the floodwall. Where space is constricted, along the upper right descending bank of the Manoa-Palolo Canal, Tieback I-Walls will be constructed, with no walking path.

The floodwall profiles along the right bank of the Ala Wai Canal can be seen in Figure 7-20 through Figure 7-23 below. The floodwall profiles along the left bank of the Ala Wai Canal can be seen in Figure 7-24 through Figure 7-28 below. And finally, a summary table of the Ala Wai Canal floodwall features is shown below in Table 7-1.

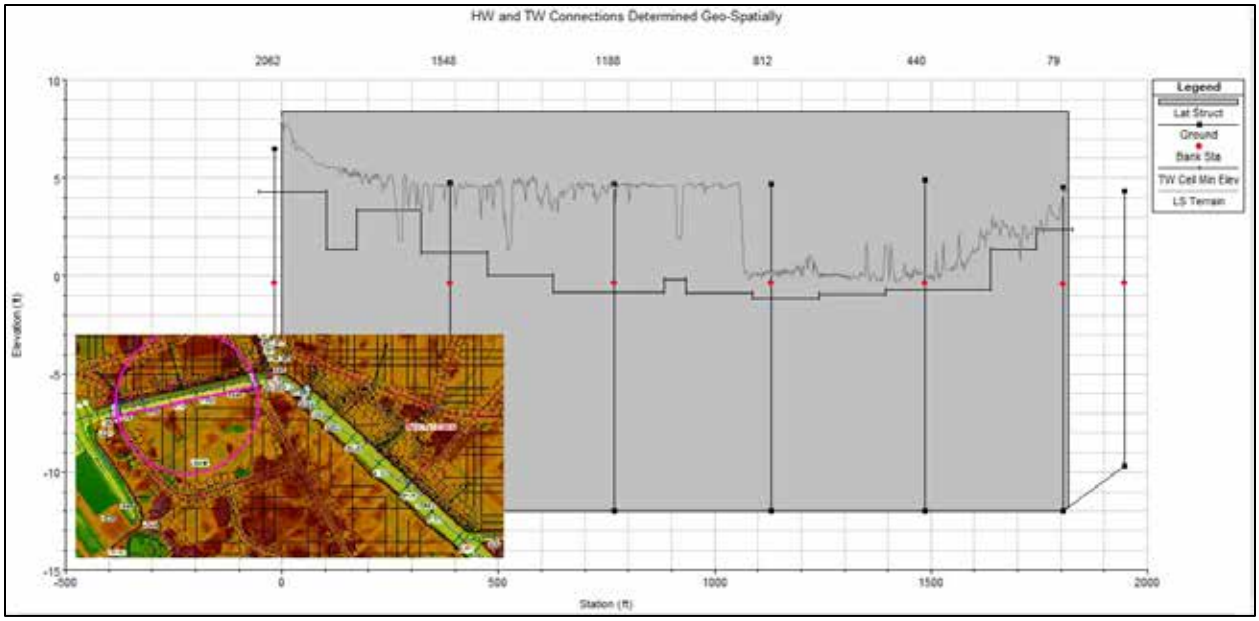

Figure 7-28: Ala Wai Left Bank Floodwall Profile from Kalakaua Avenue to Ala Moana Boulevard

As mentioned in Section 3.2.1, where the new Lidar data along the Ala Wai Canal and the new post dredge bathymetric survey was discussed, there is some risk associated with using the surveyed post dredge bathymetric data. There is a gradual reduction of depth and associated conveyance area in the canal as time goes on due to sediment buildup before the next dredging occurs. A sensitivity of the post dredge survey channel vs the MMC model channel representing a large sediment buildup was conducted to see the possible range of water surface elevations that can occur during the canal sediment cycle of filling up, and then dredging again, for Alternative 5.3. For the modeled Alternative 5.3 10% AEP flood with full sedimentation in the canal, there is up to a 1.0 foot increase to the Upper Ala Wai Canal water surface elevations, and for the modeled Alternative 5.3 1% AEP flood with full sedimentation in the canal, there is up to 0.5 foot of increase due to sediment. It is assumed that the canal will continue to be dredged, as needed, for sediment maintenance. Sedimentation of the Ala Wai Canal will be a risk factor during the Risk Assessment and during PED phase.

Table 7-1: Alternative 5.3 Features Summary Table

Measure	Structure Type1	Maximum Wall Height	Total Wall Length	Number of Road Closures	Number of Drainage Structures2	Number of Flapgates2
Woodlawn Drive Floodwall	L-wall on Macropiles	6 ft	1,270 ft	1	--	--
Koali Road Floodwall	L-wall on Macropiles	6 ft	2,510 ft	2	2	2
Ala Wai Golf Course Detention	Berm (8,315 ft) L-wall on Macropiles3 (1,861 ft)	6-9 ft	10,176 ft	1	5	5
Ala Wai Canal Floodwall4	J-wall on Macropiles3 (17,125ft) L-wall on Macropiles3 (4,069 ft) Tieback I-Wall3 (1,658 ft)	6 ft	22,852 ft	11	14	59

1 Berms assumed to be 6-9 feet tall and have side slopes of 3H:1V with a 12-foot crown. L-walls along the Ala Wai Canal assumed to be 6 feet tall with a 12-foot-wide X 40-inch-thick base supported on 16-inch diameter by 40 feet long cased macropiles with a 14-inch outer diameter X ½-inch thick full-length permanent casing and a full-length No. 11 all-thread center bar. The macropiles to be in two rows with 5-foot on-center spacing, with the first row vertical and the second row battered at 6V:1H. L-walls at the Golf Course assumed to be 9 feet tall with a 13-foot-wide X 44-inch-thick base supported on 18-inch diameter by 50 feet long cased macropiles with an 18-inch outer diameter X ½-inch thick full-length permanent casing and a full-length No. 11 all-thread center bar. The macropiles to be in two rows with 5-foot on-center spacing, with the first row vertical and the second row battered at 6V:1H. J-wall assumed to be the same design as 6-ft L-walls (i.e., same width, macropiles configuration, etc.), except the wall will include a 3-foot-tall concrete wall on the heel, with the 3-foot-deep area created between the front and rear walls backfilled with soil to create an elevated walkway along the Ala Wai Canal. Tieback I-Wall (tied-back I-wall) assumed to be toed into rock or extended 15 feet below the stream level with PZ30 sheet piles and 50-foot-long angled ties at 7 feet on-center with a continuous HP12X53 waler located 6 feet below the streambank crest.

2 Indicates the number of assumed outlet structures. It is assumed that existing storm drains larger than 36 inches will require a drainage structure (and positive closure). Smaller sizes may require drainage structures during future design phases.

3 J-wall on Macropiles assumed to be used along the Ala Wai Canal only. L-wall on Macropiles assumed to be used adjacent to streams where visibility of the canal is not a major consideration and where erosion is more of a concern, while the I-wall assumed to be used in areas away from streams where there is flat ground and erosion is not a concern; however, there are no I-walls in the TSP. The Tieback I-Wall will be used where space limitations and vibrations are major considerations and prevent the use of the other wall types (i.e., specifically planned on the Manoa-Palolo Stream from Date Street to Kapiolani Boulevard).

4 The floodwall around the canal also accounts for four canoe closure structures.

7.3.4. Other measures investigated for the reduction of induced damages.

Many other measures were investigated for reducing the induced damages, including changing of floodwall alignments and heights, changing golf course detention alignments and heights, multiple Makiki Stream floodwall design heights, adding a low flow channel into the Makiki Stream, and pumps. Over forty iterations of these measures were modeled. Some of these made the induced damages worse, some made no significant change added to costs, and a few helped hydraulically but were deemed not constructable by the PDT due to other constraints or costs.

7.3.4.1. Ala Wai Golf Course Detention

Many configurations of the Golf Course Detention basin were investigated. Many configurations of the levee alignment were looked into, along with multiple iterations of levee heights. Further, the inflow into the Golf Course Detention was investigated with different weir placements, lengths, and heights. Investigating how the Kaimuki High School storage area impacts the Golf Course Detention and allowing water to flow into the Golf Course Detention from that area over Date Street was investigated. The current design of the Ala Wai Golf Course Detention provided the best optimization of those features to create the most storage capacity with the least impact to utilities and costs. Increasing the detention levee heights from 6 ft to 9 ft, an increase up to an elevation of 12 ft msl, reduced the induced impacts in the damage reaches along the Ala Wai canal, especially in the two north of the Ala Wai Canal.

7.3.4.2. Ala Wai Canal Floodwall

The current design of the Ala Wai Canal floodwall alignment provided the most protection for the more frequent flood events with decreasing some of the induced impacts that the previous alignment in Alternative 5.2 caused.

7.3.4.3. Makiki Stream Floodwall

Multiple measures for reducing the induced damages along the Makiki Stream were investigated. The Makiki Floodwalls helped to reduce the inundations for the larger flood events, but the increased WSEL carried upstream and caused additional flows to leave the channel upstream of where the floodwalls started, especially for the smaller more frequent flood events. Extending the floodwalls upstream was deemed not constructable to due multiple constraints, including geotechnical issues, structural issues, utilities, and required closures. A low flow channel cut into the existing channel of the Makiki Stream downstream of Fern Street was investigated to help increase conveyance near the confluence with Ala Wai Canal. While this did have a small positive impact hydraulicly, it was determined that the cut would destabilize the existing channelized stream walls, and the costs to rebuild the entire canal wall system would be infeasible due to all the space constraints.

7.3.4.4. Pumps

The construction of a pump station(s) located along Makiki Stream where most of the induced flooding is occurring was investigated during the reduction of induced damages analysis. The purpose of the pumping station(s) would be to mitigate for flooding in the Makiki Stream area due to increased water surface elevations that propagated up the Makiki a little due to Ala Wai Canal backwater and from the interior flooding that was induced by the Ala Wai Canal floodwalls during large storm events. Modeling was conducted with one 500 cfs pump placed in the left overbank of the Lower Makiki Stream and one 500 cfs pump placed in the right overbank of the Lower Makiki Stream. The location of the pumps was not placed inline but were placed in ponding areas without consideration of real estate needs and constructability. As the number and precise location of permanent pump stations is unknown at this time, modeling shows that each of the pump stations would need a pumping capacity range between 500 cubic feet per second (cfs) up to a few thousand cfs, which would be very large pump stations. Permanent pump stations would likely consist of a wet well installed in a low-lying area where water naturally flows. The wet well would consist of a concrete inlet box with mesh screens for debris and wildlife protection, hinged lid for pump removal for maintenance, etc. The outlet from the wet well would be routed to the floodwall and would either pass over the wall or through it with a check valve to prevent inflow from the river side. The wet well would connect to a pump house. The pump house would be elevated and would hold the electrical infrastructure and other operating equipment, and a backup generator to minimize pump failure in the event of power disruption. The pumps would need to be designed to mitigate for induced flooding; however, pumps alone would not fully mitigate for induced flooding. The PDT determined that the pumps were not feasible for the induced damages due to the real estate issues, constructability, and the extremely high costs associated with the features described above for this measure.

Any while pumps directly on the Ala Wai Canal were not further investigated during the reduction of induced damages, the PDT felt that the results of the previously screened pump measures, the analysis which was described in Section 4.4 would still be applicable. The volume of discharge and the slope of the energy grade in the Ala Wai and up the Makiki Stream tributary would result in very minimal and localized benefits that would not be propagated up the system to the main induced damages areas.

8. TSP RESULTS

The Future Without Project model runs were compared to the Future With Project results for Alternatives 5.1, 5.2, and 5.3 at select cross sections, the Index Cross Sections for the Economic Analysis, in the Ala Wai Watershed. The locations are shown in Figure 6-1.

8.1. Water Surface Elevations and Discharge

Tables the water surface elevations and discharges for Alternatives 5.1, 5.2, and 5.3 are shown below for all of the eight flood profiles in Table 8-1 to Table 8-8.

8.2. Flood Inundation Maps

Flood inundation maps for the Future Without Project conditions are shown in Section 6.2, so only the Flood Inundation for Alternative 5.3 are shown below.

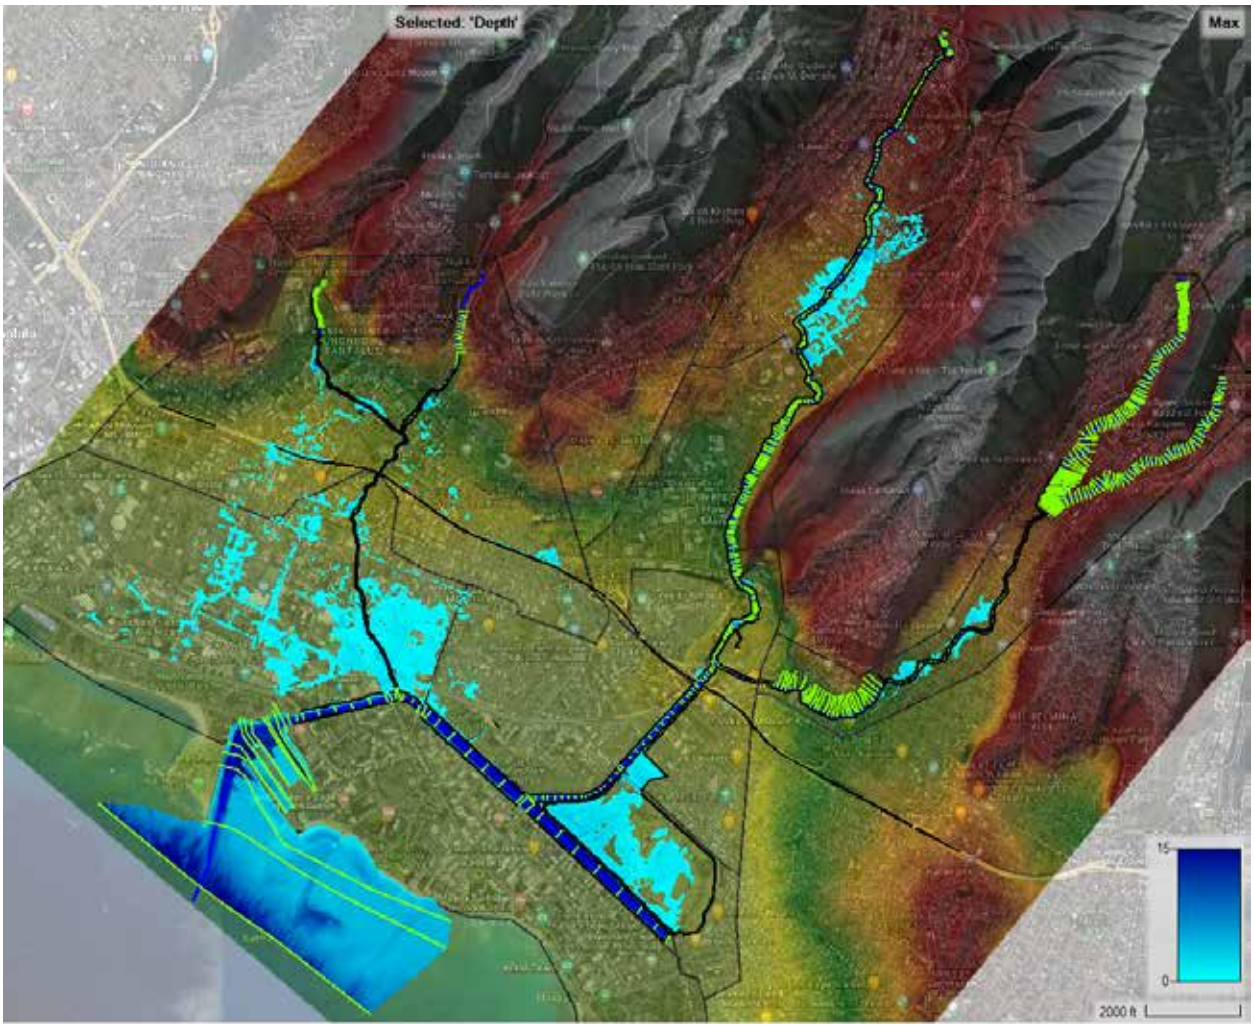

Figure 8-1: Alt 5.3 Flood Inundation Depths for the 10% AEP

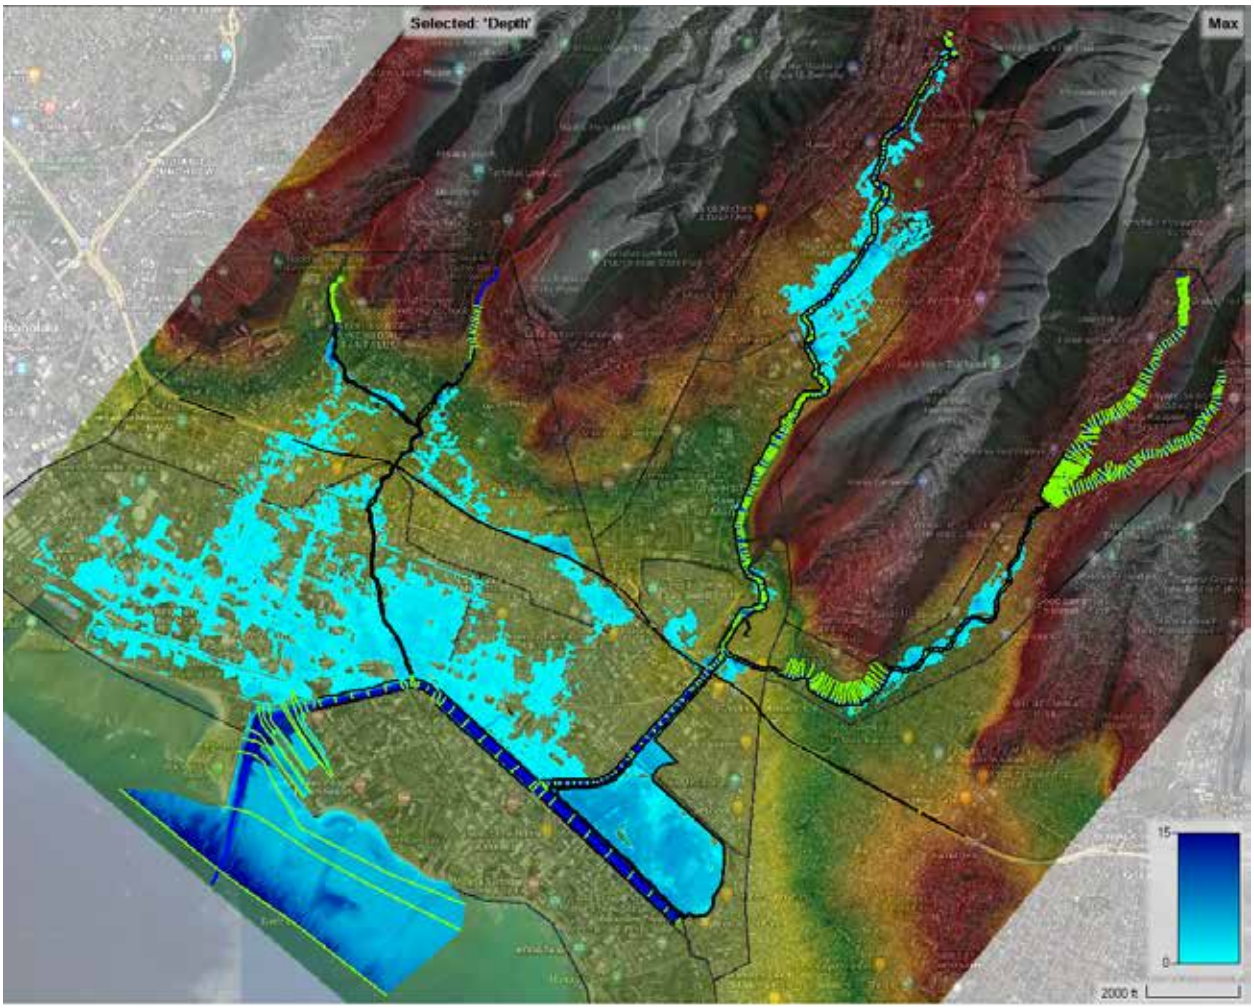

Figure 8-2: Alt 5.3 Flood Inundation Depths for the 2% AEP

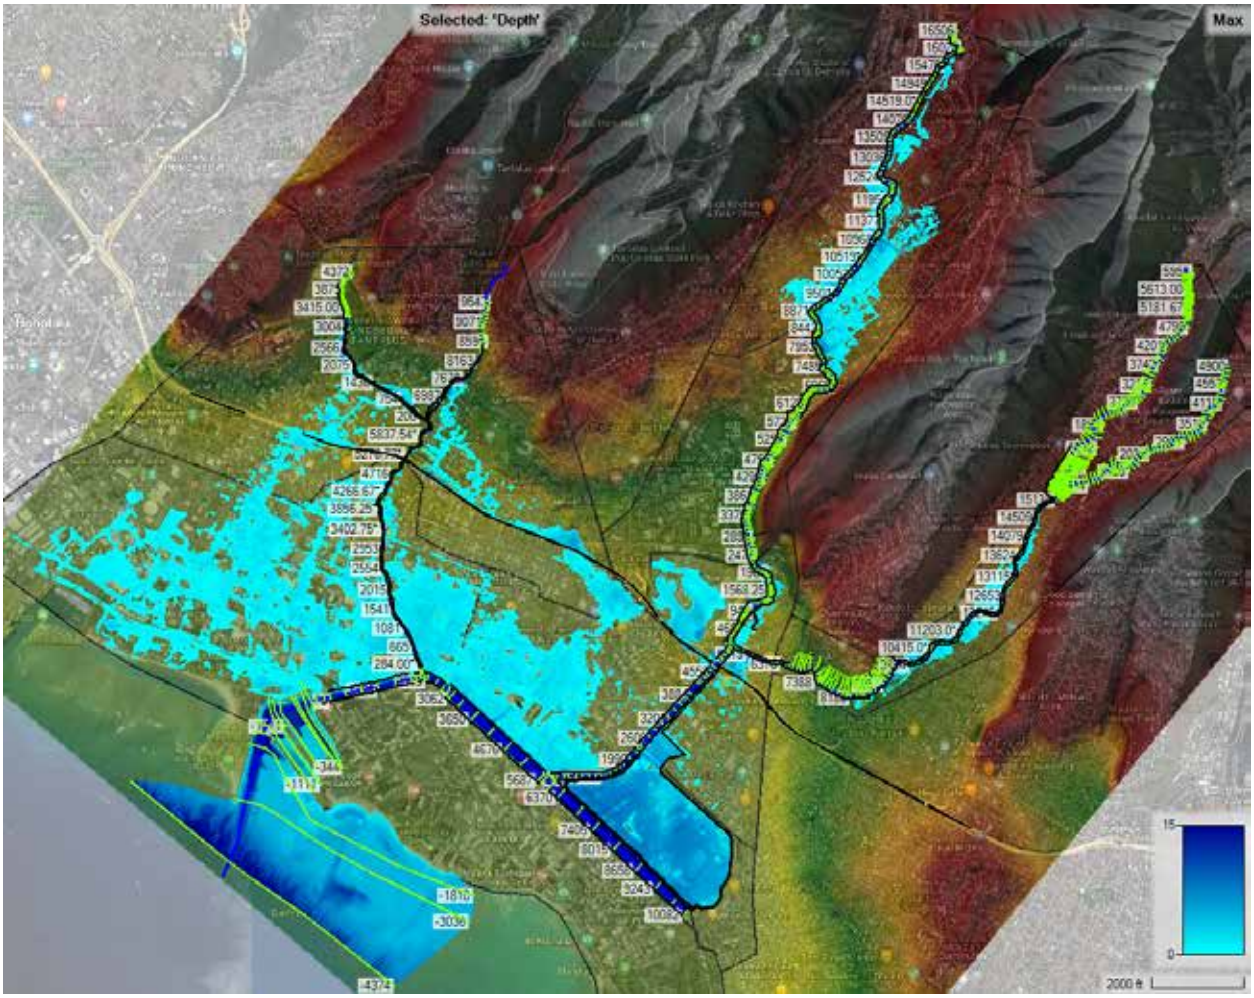

Figure 8-3: Alt 5.3 Flood Inundation Depths for the 1% AEP

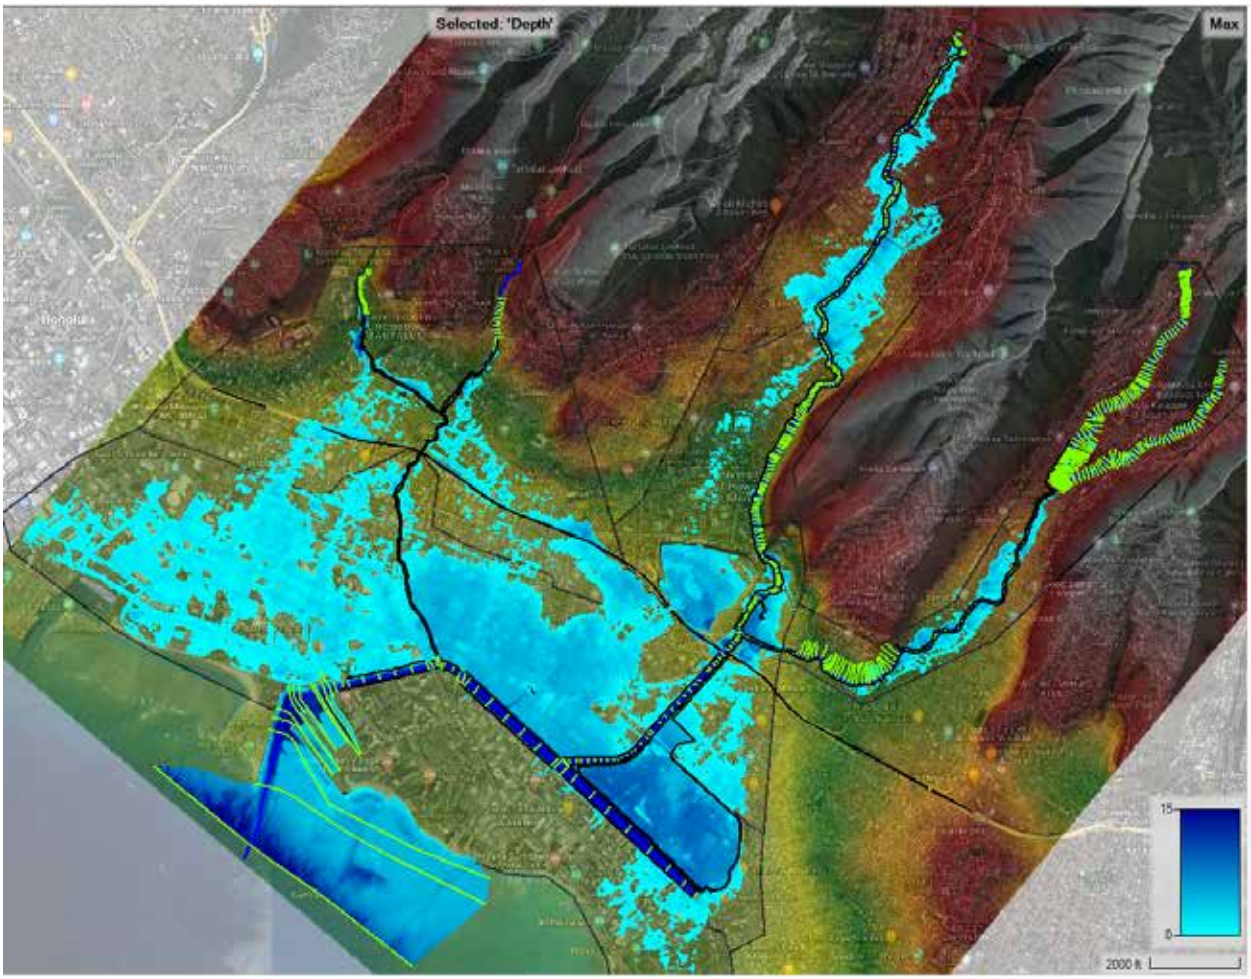

Figure 8-4: Alt 5.3 Flood Inundation Depths for the 0.2% AEP

8.3. Velocities and Shear Stress for the Recommended Plan, Alternative 5.3

The purpose of the floodwalls is to provide a barrier against flood inundation and to protect structures from hydrostatic and hydrodynamic loads. These barriers keep the flood discharges within the channels until they reach the top of the floodwall and start to overtop the floodwalls. The 6-foot heights of the floodwalls were chosen to help prevent overland flooding in some locations for the lower, more frequent flood events, while maintaining the viewshed and being constructable, both in design and costs. While these 6-foot-high levees do not protect against the larger, less frequent flood events, they do still reduce the flooding in the targeted locations.

When floodwalls keep the discharge within the channel, however, the water surface elevations increase along with the velocities. This can cause induced damages in other areas of the watershed and can increase the potential for erosion within the channel or along the banks. The overland flood flow velocities will decrease. See Figure 8-1 for the Future Without Project overland flood map for the 1% AEP event and the velocities in the overbanks. See Figure 8-2 for Alternative 5.3, the recommended plan.

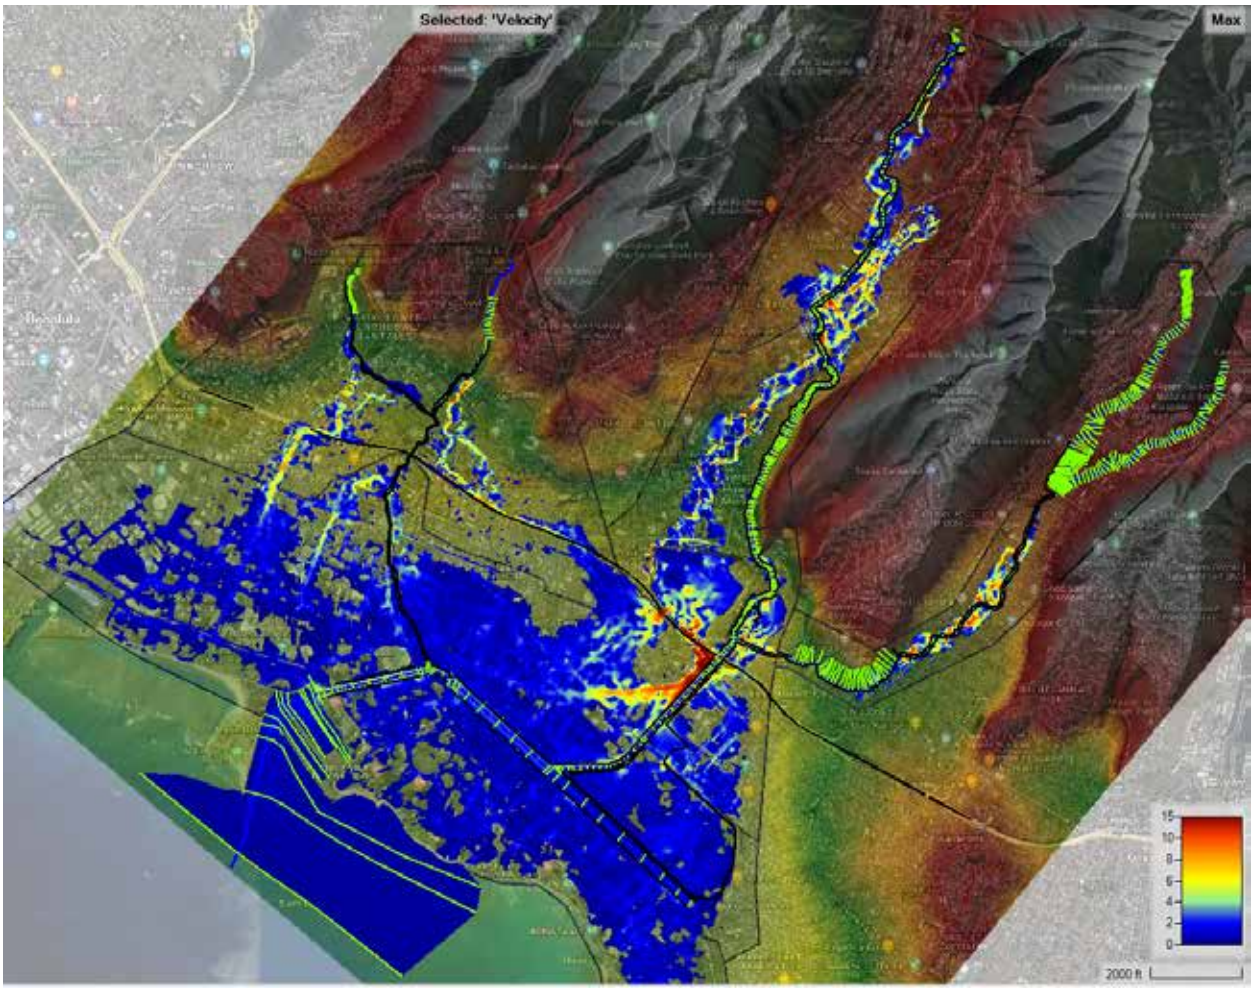

Figure 8-5: FWOP Overland Flood Velocities for the 1% AEP

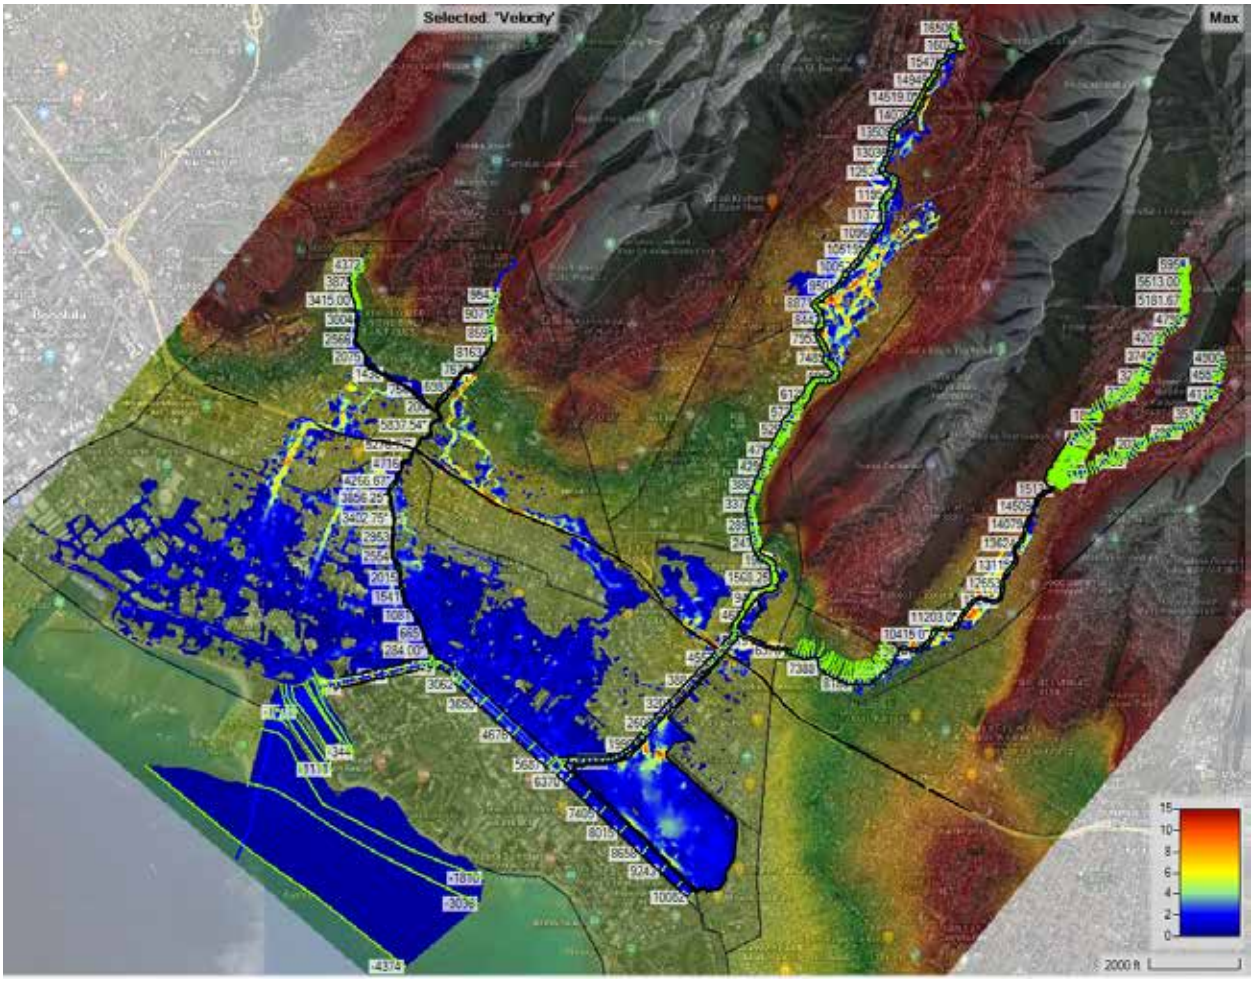

Figure 8-6: Alt 5.3 Overland Flood Velocities for the 1% AEP

One method of investigating the impacts of floodwalls on the channel and banks is by looking at the mean channel velocities of the FWOP and Recommended Alternatives and how they change, and as compared to the channel material. A table of the allowable velocities for channel design from the USDA NRCS (Part 654 Stream Restoration Design National Engineering Handbook, August 2007) is shown below in Table 8-9.

Table 8-9: Allowable Velocities for Threshold Channel Design from the USDA NRCS Stream Restoration Design National Engineering Handbook

Table 8–4 Allowable velocities

Channel material	Mean channel velocity (ft/s)	(m/s)
Fine sand	2.0	0.61
Coarse sand	4.0	1.22
Fine gravel	6.0	1.83
Earth		
Sandy silt	2.0	0.61
Silt clay	3.5	1.07
Clay	6.0	1.83
Grass-lined earth (slopes <5%)		
Bermudagrass		
Sandy silt	6.0	1.83
Silt clay	8.0	2.44
Kentucky bluegrass		
Sandy silt	5.0	1.52
Silt clay	7.0	2.13
Poor rock (usually sedimentary)	10.0	3.05
Soft sandstone	8.0	2.44
Soft shale	3.5	1.07
Good rock (usually igneous or hard metamorphic)	20.0	6.08

8.3.1. Woodlawn Drive Floodwall

The average channel velocities and shear stress was investigated for the area of the Woodlawn Drive Floodwall. The changes to the 1% AEP values from the FWOP to Alternative 5.3, the recommended plan, are shown below for the Woodlawn Drive Floodwall in Figure 8-7 and in Table 8-10. The changes are relatively minor and within the range for the existing channel material, see Figure 8-8 and Figure 8-9. While there does not appear to be a significant impact, a full erosion and scour analysis is recommended for the PED phase.

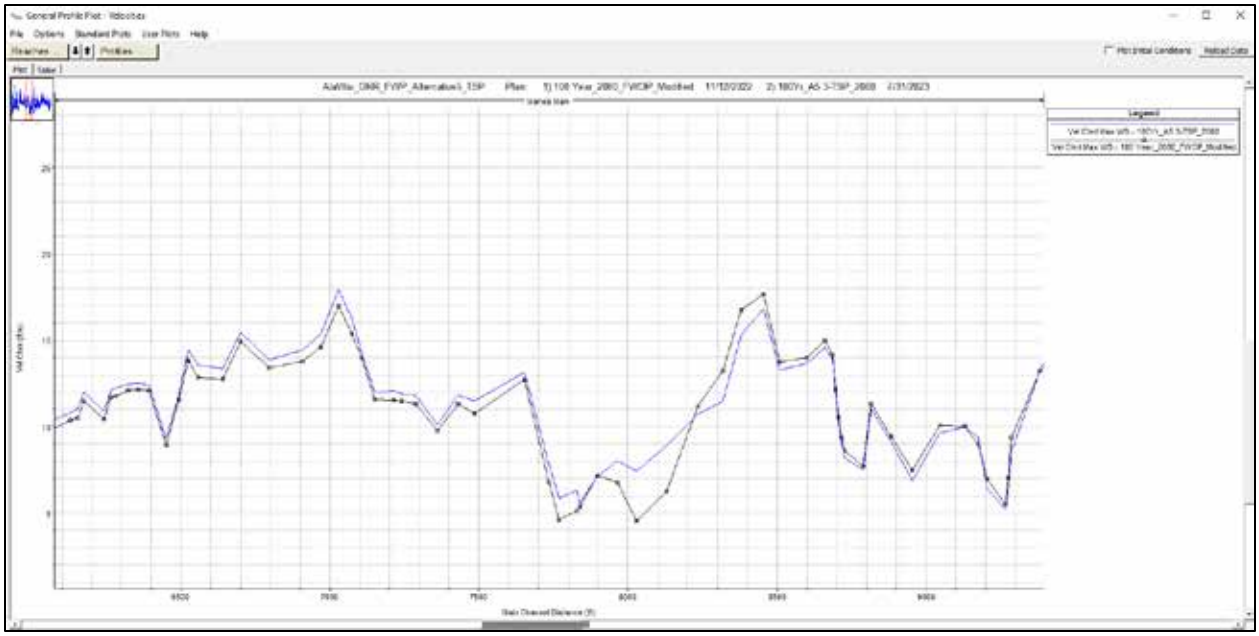

Figure 8-7: Average Channel Velocity for the 1% AEP Flood Event for the FWOP and Alternative 5.3 in the Woodlawn Drive Floodwall Area.

Table 8-10: Average Channel Velocity and Shear Stress for the 1% AEP Flood Event for the FWOP and Alternative 5.3 in the Woodlawn Drive Floodwall Area

Figure 8-8: Manoa Stream upstream of Woodlawn Drive

Figure 8-9: Manoa Stream downstream of Woodlawn Drive

8.3.2. Koali Road Floodwall

The average channel velocities and shear stress was investigated for the area of the Koali Road Floodwall. The changes to the 1% AEP values from the FWOP to Alternative 5.3, the recommended plan, are shown below for the Koali Road Floodwall in Figure 8-10 and in Table 8-11. The changes are relatively minor in the upstream portion of the Koali Road Floodwall but increase a bit near the small drop in the channel. The drop is rock, and the banks are stone revetment on the left bank and stone and vegetative on the right bank, see Figure 8-11. The increase in velocities and shear stress are less than the 20 ft/s criteria for stone, but it is still recommended that this is further investigated during the PED phase to ensure stability.

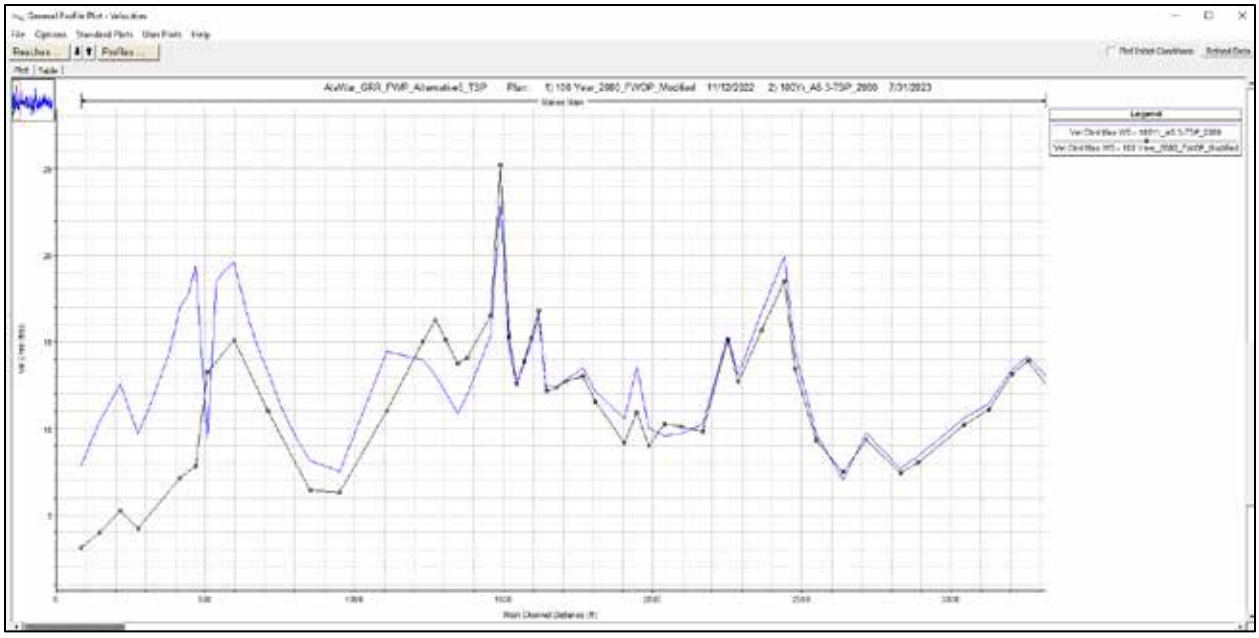

Figure 8-10: Average Channel Velocity for the 1% AEP Flood Event for the FWOP and Alternative 5.3 in the Koali Road Floodwall Area

Table 8-11: Average Channel Velocity and Shear Stress for the 1% AEP Flood Event for the FWOP and Alternative 5.3 in the Koali Road Floodwall Area

Figure 8-11: Manoa Stream at Koali Road, looking downstream.

8.3.3. Manoa-Palolo Canal portion of the Ala Wai Canal Floodwall

The average channel velocities and shear stress was investigated for the area of the Manoa-Palolo Canal portion of the Ala Wai Canal Floodwall. The changes to the 1% AEP values from the FWOP to Alternative 5.3, the recommended plan, are shown below for the Manoa-Palolo area of the Ala Wai Canal Floodwall in Figure 8-12 and in Table 8-12. The changes are relatively minor and within the range for the existing channel material in the downstream portion of the reach. There is an increase in the area between the King Street Bridge (RS 4501) and Kapiolani Boulevard (RS 4031), but that is in an area where the banks are armored in stone, see Figure 8-13 and Figure 8-14. The increase in velocities and shear stress are less than the 20 ft/s criteria for good stone, but it is still recommended that this is further investigated during the PED phase to ensure stability.

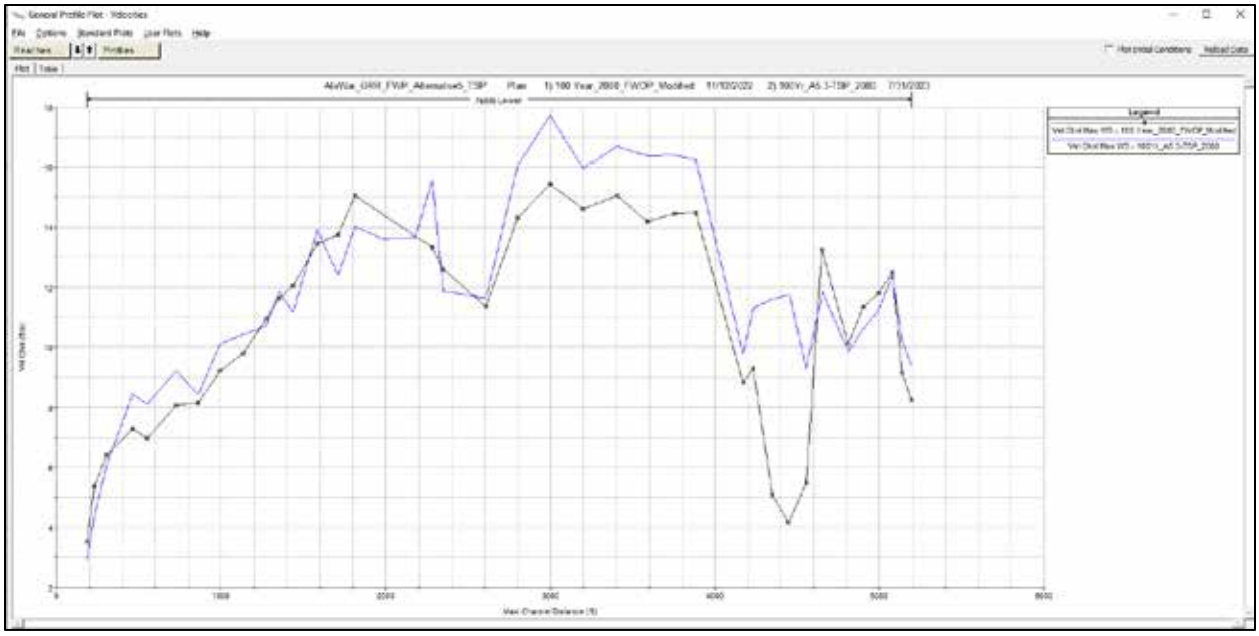

Figure 8-12: Average Channel Velocity for the 1% AEP Flood Event for the FWOP and Alternative 5.3 in the Manoa-Palolo Area of the Ala Wai Canal Floodwall

Table 8-12: Average Channel Velocity and Shear Stress for the 1% AEP Flood Event for the FWOP and Alternative 5.3 in the Manoa-Palolo Area of the Ala Wai Canal Floodwall

Figure 8-14: Manoa Stream on King Street, looking downstream.

8.3.4. Ala Wai Canal Floodwall

The average channel velocities and shear stress was investigated for the Ala Wai Canal Floodwall. The changes to the 1% AEP values from the FWOP to Alternative 5.3, the recommended plan, are shown below for entire length of the Ala Wai Canal Floodwall in Figure 8-15, and the area with the largest velocities and change in velocities are shown in Table 8-13. The changes are relatively minor and within the range for the existing channel material the Ala Wai Canal. There is an increase in the area between the McCully Street (RS 2910) and Ala Moana Boulevard (RS 73), see Figure 8-16 and Figure 8-17. The increase in velocities and shear stress are less than the canal capacity, but it is still recommended that this is further investigated during the PED phase to ensure structural stability.

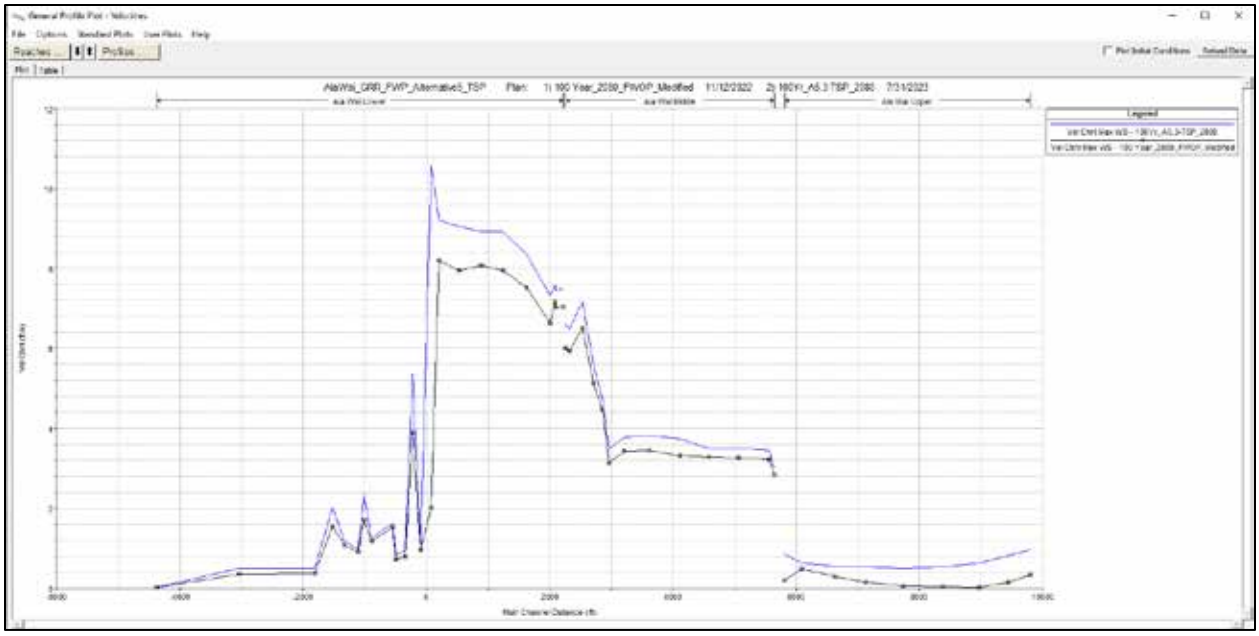

Figure 8-15: Average Channel Velocity for the 1% AEP Flood Event for the FWOP and Alternative 5.3 along the Ala Wai Canal Floodwall

Table 8-13: Average Channel Velocity and Shear Stress for the 1% AEP Flood Event for the FWOP and Alternative 5.3 at the Ala Wai Canal Floodwall in the area of the Maximum Channel Velocity and increase in Velocity.

9. Economic Analysis

H&H worked with the Economic PDT members to develop the damage reaches and the index cross sections for this General Reevaluation Study. The damage reaches changed significantly from the Validation Study to reduce the number of reaches and to better match the measures in the General Reevaluation Study alternatives, and the representative Cross Sections have been modified accordingly.

9.1. Damage Reaches

The study area was divided into 14 damages reaches based on similar topography, hydromorphology, hydraulic characteristics, and plan formulation measures. Figure 9-1 depicts study area reach boundaries.

Figure 9-1: Study Area Reach Delineations

9.2. Index Cross Sections

Each reach is associated with an index station, which is used to specify discharge-probability, stage-discharge, stage-damage functions, and top of bank elevations for each reach. The index station assignments are based on hydrologic parameters and hydraulic conditions specific to each reach. The assigned index station is generally representative of the conditions throughout the reach. Terrain elevations increase quickly throughout the study area, particularly in reaches AW7 through AW9. In these reaches, the index station is less representative of the changing conditions throughout the reach. Figure 9-2 shows the locations of the index cross sections and Table 9-1 includes the index cross sections and the bank elevations associated with the index station for each alternative.

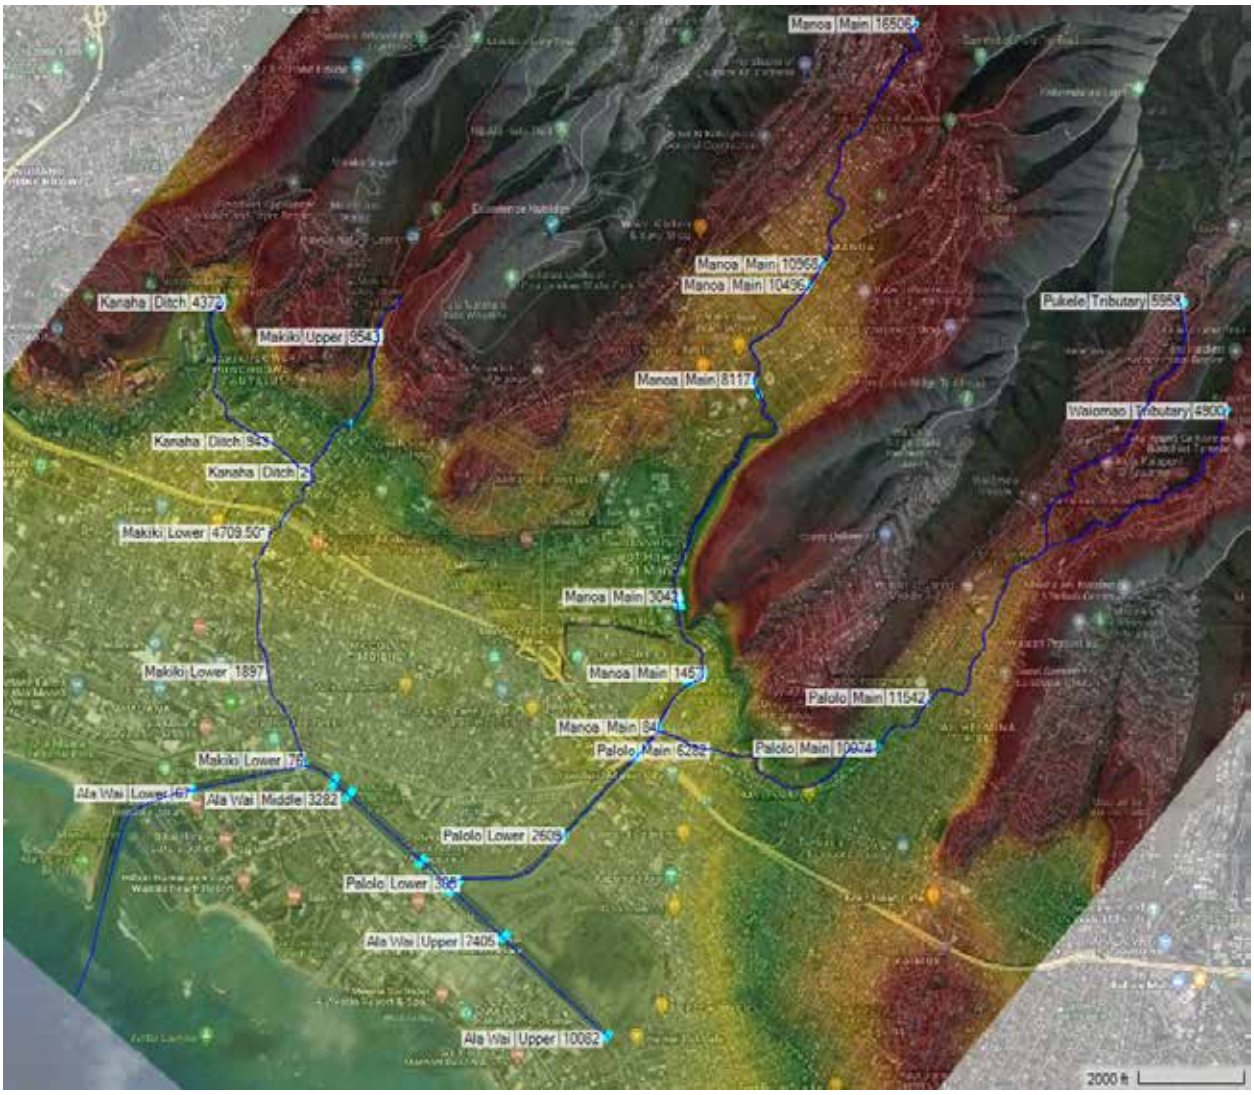

Figure 9-2: Location of Index Cross Sections

Table 9-1: Index Cross Sections and Associated Banks for each of the Alternatives. Ones highlighted in blue are modified from the FWOP.

9.3. Uncertainty for Discharge Relationships

See Section 1.3 and Addendums A and B for background on development of the frequency flows used in this study and Appendix C relative to application of model results to the Economic analysis. While the Validation Study developed uncertainty estimates for discharge for use in the economic and Flood Damage Reduction Analysis software HEC-FDA ("FDA"), many discussions were held between the economist, the hydrologic engineer, the MMC, and HEC relative to changes in the economic damage reaches and relative changes in the Equivalent Record Length (ERL) used in the FDA statistical analysis From those discussions, HEC had stated that they agreed with the general process the MMC used for the Validation Study, but that it omitted the uncertainty in the transform of precipitation to runoff. HEC stated that omitting that uncertainty makes the Equivalent Record Length (ERL) used in previous analysis too high. This is a change in guidance from the recommendations of the RMC during the Validation Study. USACE is currently updating the methods of statistical analysis that defines ERL due to the software changes in FDA from 1D to gridded 2D modeling capabilities and will update EM 1110-2-1619, but final guidance has not been formalized or released yet.

From the discussions with the subject matter experts, the economist determined the most appropriate method for this study's FDA model was the graphical method, which was used to generate probability-discharge functions. Uncertainty was computed using an ERL (N) of 50 years, which was qualitatively based upon the recommended ERL in Table 4-5 of EM 1110-2-1619 and other considerations: Per this table, an ERL for a well calibrated rainfall-runoff-routing model was recommended to be 20 to 30 years. Consideration was given to the historic gauge records available within the watershed (see Section 3.5.1), the long periods of rainfall records that contributed to the precipitation frequencies, and the methodologies used in determining the computed frequency flows using the historically calibrated model with HEC-WAT for numerous iterations. Selecting an ERL of 50 years was deemed appropriate to reflect that greater confidence in the flow discharges, also considering the understanding from HEC that historical experience has shown that the recommended ERL within EM 1110-2-1619 are generally low. The “Less Simple” method of Order Statistics was used to approximate uncertainty with a standard normal distribution. Since HEC-FDA 1.4.3 was used, 173 points were included in the standard probabilities for graphical probability functions.

9.4. Stage-Discharge Function with Uncertainty

In HEC-FDA, the stage-discharge information is imported from the water surface profile information from HEC-RAS model that is detailed in the section above. The Validation Study went through a full analysis of the MMC model, the base model for this study, to determine the stage-discharge function uncertainty. For the Validation study, a normal distribution was used to represent uncertainty for this data and that option required a standard deviation for each damage reach. The standard deviation was determined by running a sensitivity on the Manning’s “n” values in the HEC-RAS model. To test the sensitivity, model runs were made with the “n” values varying on average by +/- 20% for the without project plan, post-feasibility TSP plan, and the proposed final features plan. The range of roughness values was estimated at each location to determine a realistic high and low value for the area. The difference in stage between the high estimate and low estimate was calculated for each cross-section. For each damage reach, an average stage difference was determined for the cross-sections contained within the damage reach. To estimate the standard deviation relative to the mean stage for the

95% confidence interval for a normal distribution, the difference in stage between the high and low was divided by 4 (+/- 2 standard deviations). This was done for the FWOP, Post-Feasibility TSP, and the Proposed Final Features. Those calculations showed that for the FWOP run, the highest standard deviation was 0.43 ft; for the Post-Feasibility TSP run, the highest standard deviation was 0.41 ft; and for the Proposed Final Features run, the highest standard deviation was 0.46 ft. The calculated standard deviations for each damage reach for the different project configurations can be found in the Validation Study H&H Appendix Hydraulic Report, which is included as an Addendum to this Appendix, for their study.

The Engineer Manual (EM) 1110-2-1619, Risk Based Analysis for Flood Damage Reduction Study, however, provides guidance on determining standard deviations. Table 5-2 from EM 1110-2-1619 describes the minimum standard deviation of error in stage that can be used for a flood damage reduction study. The table was reproduced and is shown below in Table 9-2. As stated in the Terrain section of the Validation Report, the LiDAR data has an accuracy of 45 cm (1.5 ft) horizontal, 37 cm (1.2 ft) vertical and was processed with 1 ft horizontal point spacing and survey data was provided for some channel data. The Manning's “n” values were considered "Fair" due to the limited calibration data and coupled with the use of LiDAR and survey data, the minimum standard deviation of error in stage was determined to be 0.7 ft. Since the calculated standard deviations for every reach was lower than the minimum standard from EM 1110-2-1619, a 0.7 ft standard deviation was adopted for all reaches across the 3 project configurations.

Table 9-2: Minimum Standard Deviations of Error in Stage (Table 5-2 from EM 1110-2-1619)

Manning's n Value Reliability[1]	Standard Deviation (in feet)	
	Cross Section Based on Field Survey or Aerial Spot Elevation	Cross-section based on Topographic Map with 2-5' Contours
Good	0.3	0.6
Fair	0.7	0.9
Poor	1.3	1.5

[1]Where good reliability of Manning's *n* value equations relate to excellent to very good model adjustment/validation to a stream gauge, a set of high-water marks in the project effective size range, and other data. Fair reliability relates to fair to good model adjustment/validation for which some, but limited, high-water mark data are available. Poor reliability equates to poor model adjustment/validation or essentially no data for model adjustment/validation

As there were only minor changes made to the base existing Future Without Project conditions model, and most of those were due to updated lidar data in the limited overbank area along the Ala Wai Canal and bathymetric survey data of the Ala Wai canal, and all the other reaches and channel n-values are the same, it has been determined that the Validation Analysis of the uncertainty for the FWOP runs is still valid, and as both of the Validation alternatives included more measures than our recommended plan and were designed for larger flood events and still under 0.5 ft, less than the minimum standard deviation required, it was determined that the

Validation Analysis of the uncertainty would still be valid for our alternatives and our recommended alternative.

10. Analyses not conducted with this TSP

It should be noted that there are a couple of analysis that have not been conducted for this TSP. The PDT has determined that they will be completed in later phases of the study.

10.1. Risk Assessment

USACE defined risk assessment in a white paper (al, 2007) as follows: "Risk assessment is a broad term that encompasses a variety of analytic techniques that are used in different situations, depending upon the nature of the risk, the available data, and needs of decision makers. It is a systematic, evidence based approach for quantifying and describing the nature, likelihood, and magnitude of risk associated with the current condition and the same values resulting from a changed condition due to some action." A risk assessment is a critical component of a flood risk management project, and one will be conducted after the TSP.

10.2. Interior Drainage

The PDT determined that the interior drainage analysis will be conducted during the PED phase of the study. A full interior drainage analysis will be conducted according to EM 1110-2-1413, Hydrologic Analysis of Interior Areas, at that time.

Executive Summary

Introduction

In 2001, the United States Army Corps of Engineers (USACE) recommended flood mitigation and ecosystem restoration measures for the Ala Wai Watershed, located on the southeast sector of the island of Oʻahu, Hawaiʻi. As part of this larger goal, USACE contracted Oceanit to develop a Hydrologic Engineering Center Hydrologic Modeling System (HEC-HMS) for a range of potential storms in the Ala Wai Watershed. HEC-HMS is the USACE hydrologic model. The purpose of this study was to estimate peak flow discharges at particular drainage junctions in the Ala Wai Watershed corresponding to the following storm return periods: 2-, 5-, 10-, 20-, 50-, 100-, 200-, and 500-year. These storm return periods correlate to storm chance exceedance probabilities of 50, 20, 10, 5, 2, 1, 0.5, and 0.2 percent, respectively.

Purpose

Whereas this study focuses on the HEC-HMS model, this study uses a total of five different methods to estimate peak flow discharges throughout the Ala Wai Watershed for potential storms ranging in duration and intensity. Estimated peak flow discharges are based on the existing conditions of the Ala Wai Watershed's sub-watersheds of Makiki, Mānoa, and Pālolo valleys; Mānoa- Pālolo and Ala Wai Canals; and Waikīkī. Discharge at junctions of interest throughout these sub-watersheds was studied. Oceanit modeled storms using both rainfall-runoff and peak flow frequency methods for a range of storm scenarios, as follows. The study (1) researched and collected relevant hydrologic data; (2) constructed and calibrated both rainfall-runoff and peak flow frequency hydrologic models; and (3) weighted and compared the results from these models to arrive at estimated peak flow discharges.

Study Area

The Ala Wai Watershed encompasses a drainage area of 10,400 acres (16.2 square miles) of area that are economically significant and densely populated. The existing conditions throughout the Ala Wai Watershed are relevant to its hydrologic analysis, including the character of the watershed's overall climate, topography, geology, vegetation, land use and cover, and water resources. Hawaiʻi's high moisture, orographic rainfall, and northeasterly trade winds create wet conditions in the upper Ala Wai Watershed. The topography of the upper Ala Wai watershed is relatively steep and stony that, in combination with heavy rainfall, provides conditions prone to flash flooding. The lower Ala Wai watershed has finer well-drained soil, but much of it is urbanized, meaning its terrain surfaces are impervious. In terms of streams, the Makiki, Mānoa, and Pālolo streams drain their respective sub-watersheds. Mānoa and Pālolo streams combine to form the Mānoa-Pālolo Canal that empties into the Ala Wai Canal. Runoff and drainage from Waikīkī empties into the Ala Wai Canal as well.

Data Collection Procedure

Data collection for hydrologic analysis included rainfall gage data, stream flow gage data, records of historical storms, maps of storm drainage systems, geospatial data, and field surveys observations. Storms that occurred on December 17–18, 1967; October 30, 2004; and March 31, 2006 were used to calibrate the HEC-HMS model. The City and County of Honolulu drainage maps and University of Hawai'i's utility maps were used to determine the existing storm drainage system. Geospatial information, including LiDAR data and aerial maps established terrain roughness characteristics and stream channel cross sections. Rainfall data was extrapolated to be converted into intensity-duration-frequency (IDF) curves, illustrating rainfall intensities according to their duration.

Hydrologic Analysis Procedure

Hydrologic analysis of sub-watersheds of the Ala Wai Watershed predicted from the application of five hydrologic modeling methods: the HEC-HMS model, USGS regression method, City and County of Honolulu drainage standards Plate 6, Federal Emergency Management Agency Flood Insurance Study, and the HEC Statistics Software Package (SSP). The HEC-HMS model of the Ala Wai Watershed was the focus of this report, and the results from this model were relied on more than other methods.

SCS curve number Loss Method was applied and Clark Unit Hydrograph transform method was applied for non-urbanized areas, and the Kinematic Wave Transform Method was used for urbanized areas. The Ala Wai Canal was assumed to be a reservoir for the purposes of this study because of backwater effects that are possible in the mouth of Ala Wai Canal. Also, according to the TR-55 method, the water flow path was separated into three portions: sheet flow, shallow concentrated flow, and channel flow, which are summed to calculated time of concentration. Manning's *n* values were selected for the land surface characteristics for the Ala Wai Watershed. Curve number calculations were established according to the hydrologic soil group.

Results

Final "best" peak flow discharges were determined by comparing the various derived discharge-frequency curves graphically and by the accuracy or uncertainty of each method. Table ES-1 shows the results of peak flows discharges at the mouth of the Ala Wai Canal.

Peak Flow Discharges at Mouth of Ala Wai Canal

Return Period (yr)	2	5	10	20	50	100	200	500

Table ES-1. Peak Flow Discharges at Mouth of Ala Wai Canal (Updated March 2016)

1 Introduction

1.1 Background

In 2001, the United States Army Corps of Engineers (USACE) recommended flood mitigation and ecosystem restoration measures for the Ala Wai Watershed, located on the southeast sector of the island of Oʻahu, Hawaiʻi. These measures constitute the Ala Wai Watershed Project that encompasses a drainage area of approximately 10,400 acres of the valleys of Makiki, Mānoa, and Pālolo, and low-lying areas of Mōʻiliʻili, McCully, and Waikīkī. These areas are economically significant and densely populated, and many have high potential for flooding. Historically, floods have occurred in the Mānoa, Makiki, and Mōʻiliʻili areas due to quick concentration of storm waters that overwhelms the drainage system capacities. Depending on a storm's intensity and duration, the steep slopes of the upper Ala Wai Watershed can create flood conditions due to its steep slopes and impervious surfaces from urbanization. In the past, such as during the severe storm of October 30, 2004, flash flood waters with accumulated debris have caused significant property damage to residential, commercial, and public land (Belt Collins 1998).

Storm runoff in these areas flows through drainage systems that ultimately empty into the Ala Wai Canal. In turn, the Ala Wai Canal flows into the Pacific Ocean. The Ala Wai Canal was constructed in the 1920s, and has experienced heavy sedimentation and economic degradations since its inception (Belt Collins 1998). The proposed flood mitigation measures for the Ala Wai Watershed Project must be based on the best hydrologic and hydraulic data available.

USACE contracted Oceanit to conduct hydrologic analysis for a range of potential storms in the Ala Wai Watershed. This hydrologic study uses five different methods to estimate peak flow discharges throughout the Ala Wai Watershed for potential storms ranging in duration and intensity. Best available predictions are based on the existing conditions of the Ala Wai Watershed's sub-watersheds of Makiki, Mānoa, and Pālolo valleys, Ala Wai Canal, and Waikīkī. Also, the existing conditions of junctions along the Mānoa-Pālolo Canal were considered because of the canal's crucial position as a drainage channel between Mānoa-Pālolo and the Ala Wai Canal, where it empties. Oceanit was directed to model storms using both rainfall-runoff and peak flow frequency methods for a range of storm scenarios, as follows.

1.2 Purpose and Scope

The purpose of this study was to estimate peak flow discharges at particular drainage junctions in the Ala Wai Watershed corresponding to the following storm return periods: 2-, 5-, 10-, 20-, 50-, 100-, 200-, and 500-year. These storm return periods correlate to storm chance exceedance probabilities of 50, 20, 10, 5, 2, 1, 0.5, and 0.2 percent, respectively. The study's scope is solely hydrologic and encompasses the Ala Wai Watershed's sub-watersheds of Makiki, Mānoa, and Pālolo valleys, Ala Wai Canal, and Waikīkī. The study also examines the junctions along the Mānoa-Pālolo Canal.

1.3 Methodology

This hydrologic study provides estimated peak flow discharges for a range of storms for particular junctions throughout the Ala Wai Watershed by applying five hydrologic methods as appropriate

and necessary. The following were completed in this study: (1) relevant hydrologic data was researched and collected; (2) rainfall-runoff models were constructed and calibrated; (3) peak flow discharges based on rainfall intensity-frequency-duration curves were modeled; and (4) these peak flow discharges were weighted and compared to arrive at final results that represent the *best* estimated peak flow discharges.

First, research on the overall existing conditions in the Ala Wai Watershed study area was conducted. Section 2.1 describes these overall existing conditions, and then Sections 2.2 through 2.4 detail the existing conditions in each sub-watershed. Conditions that were necessarily evaluated for hydrologic modeling included the slope, character, elevation, vegetative coverage, acreage, and use of the sub-watershed lands. Many of these conditions were evaluated from review of existing literature, gathering of geospatial data, and inspection during field visits. This data collection is documented in Section 3.5. Sub-basins within each sub-watershed were delineated using the geospatial data (see Section 3.6). Also, Manning's *n* values, which describe land cover and roughness, were selected (see Section 4.1.5). The existing conditions of drainage systems in the study area were primarily collected from the City and County of Honolulu's Storm Drainage System Maps (Section 3.4), and were confirmed during field visits. Primarily, drainage junctions of interest in the Ala Wai Watershed were determined from evaluating the existing drainage facilities.

Second, potential storm rainfall amount determinations were extrapolated from historic rainfall data. The storm rainfall amounts that were the input for the hydrologic model are considered the meteorological model. The rainfall and stream flow data were collected from rain gage and stream flow gage records as available for the study area (see Sections 3.1 through 3.2). Records from three severe storms were collected and later used to calibrate the hydrologic model (see Section 3.3). Rainfall amounts that constitute the frequency storms in the meteorological model were gathered from a study entitled "Rainfall Frequency Study for Oahu" (Giambelluca 1984) known commonly as Report R-73. Rainfall amounts were gathered from Report R-73 for the storm chance exceedance probabilities of 50, 20, 10, 5, 2, 1, 0.5, and 0.2 percent. Intensity-Duration-Frequency curves were established for input into the model.

Third, five methods were used to model the Ala Wai Watershed's hydrology. The rainfall-runoff method used was USACE's Hydrologic Engineering Center–Hydrologic Modeling System (HEC-HMS). The peak flow frequency methods used were the United States Geological Survey (USGS) regression equations, the City and County of Honolulu (the City) Plate 6 storm drainage standards, the Federal Emergency Management Agency (FEMA) Flood Insurance Study for the City and County of Honolulu (2004), and Hydrologic Engineering Center–Statistical Software Package (HEC-SSP). The fourth step in this study was, depending on the data available, applying these methods for each sub-watershed or junctions if available for the range of potential storms: chance exceedance probabilities of 50, 20, 10, 5, 2, 1, 0.5, and 0.2 percent. The methods used for each junction (by sub-watershed) are shown in Table 1-1 and designated by a checkmark.

Table 1-1. Methods Used by Sub-Watershed Junction

J = junction; K = Makiki; M = Mānoa; P = Pālolo; MP = Mānoa-Pālolo; and mi = miles. A checkmark indicates a method that was used for a particular junction or outlet.

1.3.1 HEC-HMS Analysis

The HEC-HMS model was the primary method of this study. The HEC-HMS method is a precipitation-runoff process model that requires three components including a basin model, a meteorological model, and a control model. The basin model layout was created according to sub-basin delineation and junctions of interest. For the purposes of this study, sub-watershed refers to the larger areas of Makiki, Mānoa, Pālolo, Ala Wai Canal, and Waikīkī; the term "sub-basin" refers to the smaller sub-watersheds within these sub-watersheds to avoid confusion. Also the term "sub-basin" is commonly accepted for the HEC-HMS model delineation of small drainage areas.

1. **Basin Model:** Under the basin model, Ala Wai Watershed was divided into 38 sub-basins. The SCS loss method and Clark Unit Hydrograph transform methods were applied for upper Makiki, Mānoa, and Pālolo valleys because these areas are considered non-urban. The Kinematic Wave Transform Method was applied for the lower Makiki ,Ala Wai Canal, and Waikīkī areas because these areas are considered urban. Selected stream flow routing methods included the Muskingum-Cunge method to account for the peak flow attenuation and the Modified Puls method to account for the backwater effects for reaches collected in the Ala Wai Canal. Ala Wai Canal was modeled as a reservoir. Several basin models were created based on the calibration and determination purposes.

2. **Meteorological Model:** A meteorological model was used to specify how precipitation would be generated for each sub-watershed in the selected basin model. For calibration purposes, hyetographs were used based on the gage weights. For predictive purposes, the frequency storms were used to produce synthetic flood events, according to exceedance probabilities.

3. **Control Model:** A control model was used to set the computation parameters. This study used a five-minute time interval for all computations.

1.3.2 Peak Flow Discharge Results

Ultimately, all five of these accepted hydrologic methods offer the *best* estimated peak flow discharges at particular junctions through Ala Wai Watershed for a range of potential storms. Available results were first weighted by accuracy or uncertainty of method, and then plotted on log-probability graph paper. Selection was completed for a best fit curve function for the peak flow discharge frequency curve at each junction of interest. Final peak flow discharges are presented in Section 5.

1.4 Acknowledgements

The USACE project managers for this study were Mr. Derek Chow and Ms. Cindy Barger. The hydrologic analysis technical team consisted of Mr. Michael Wong with the USACE and Mr. Simon Li of Oceanit. Oceanit's project manager was Dr. Dayananda Vithanage with assistance from Mr. Jay Stone and Ms. Joanne Hiramatsu. Oceanit's technical staff included Ms. Frances Ajo, Mr. Robert Bourke, Mr. Kevin Gooding, Mr. Jonathan Levy, and Mr. Manabu Tagomori. Thank you to the National Climatic Data Center, Board of Water Supply (BWS), and USGS for providing rain and stream gage data pertinent to this study.

2 Study Area Description

The Ala Wai Watershed contains five sub-watersheds that are addressed in this study: Makiki, Mānoa, Pālolo, Ala Wai Canal, and Waikīkī. The Mānoa-Pālolo Canal is also addressed in terms of its drainage junctions. Section 2.1 describes the existing conditions throughout the Ala Wai Watershed, including the overall climate, topography, geology, vegetation, land use, and water resources. These conditions are similar in each of the Ala Wai sub-watersheds that are described in Sections 2.2 through 2.6.

2.1 Ala Wai Watershed

The subject of this hydrology study is the Ala Wai Watershed, which is located on the southeastern sector of the island of Oʻahu, Hawaiʻi as shown in Figure 2-1. The watershed encompasses 10,378 acres, or 16.215 square miles. The Ala Wai Watershed stretches from the Koʻolau Mountains at Puʻu Kōnāhuanui's peak (3,105 feet) down through the three urban valleys of Makiki, Mānoa, and Pālolo, to the low-lying areas of McCully, Mōʻiliʻili, and Waikīkī. Storm runoff in the watershed flows through numerous drainage systems in these areas and ultimately empties into the Ala Wai Canal. The three major sub-watersheds that constitute the Ala Wai Watershed are Makiki, Mānoa, and Pālolo; all three of these sub-watersheds are valley systems of economic significance and dense population. The Makiki, Mānoa, and Pālolo Streams receive flows from each of these valley systems, respectively (see Figure 2-2). Another Ala Wai sub-watershed is at the confluence of the Mānoa and Pālolo Streams, referred to as the Mānoa-Pālolo Canal, which empties storm water runoff into the Ala Wai Canal between the Ala Wai Golf Course and ʻIolani School. The area surrounding the Ala Wai Canal and the adjacent tourist area of Waikīkī comprise another sub-watershed. These major sub-watersheds are shown in Figure 2-2. (According to the existing conditions, sub-basins are delineated within each sub-watershed, and these sub-basin delineations are presented in Section 3, and shown in Figure 3-4.)

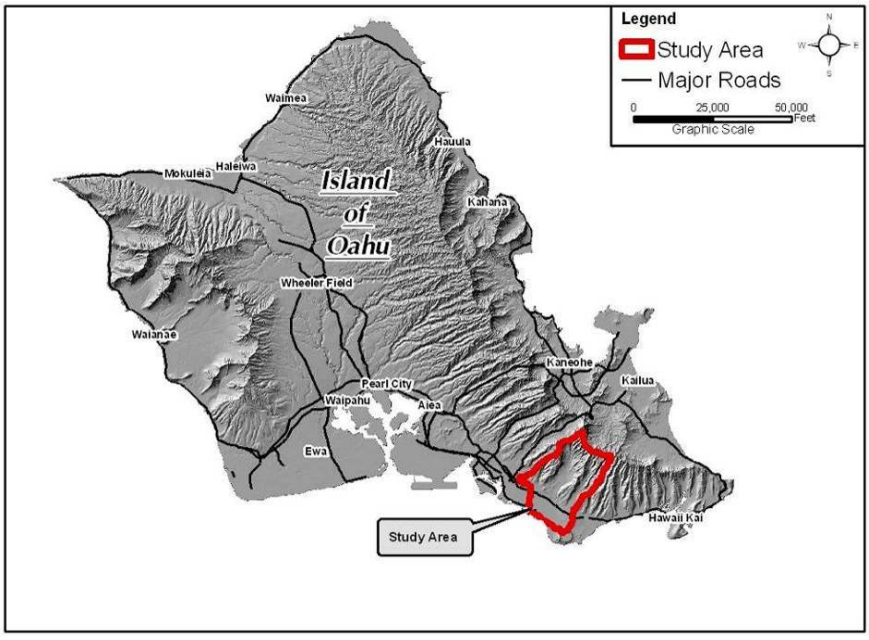

Figure 2-1. Ala Wai Watershed Location Map

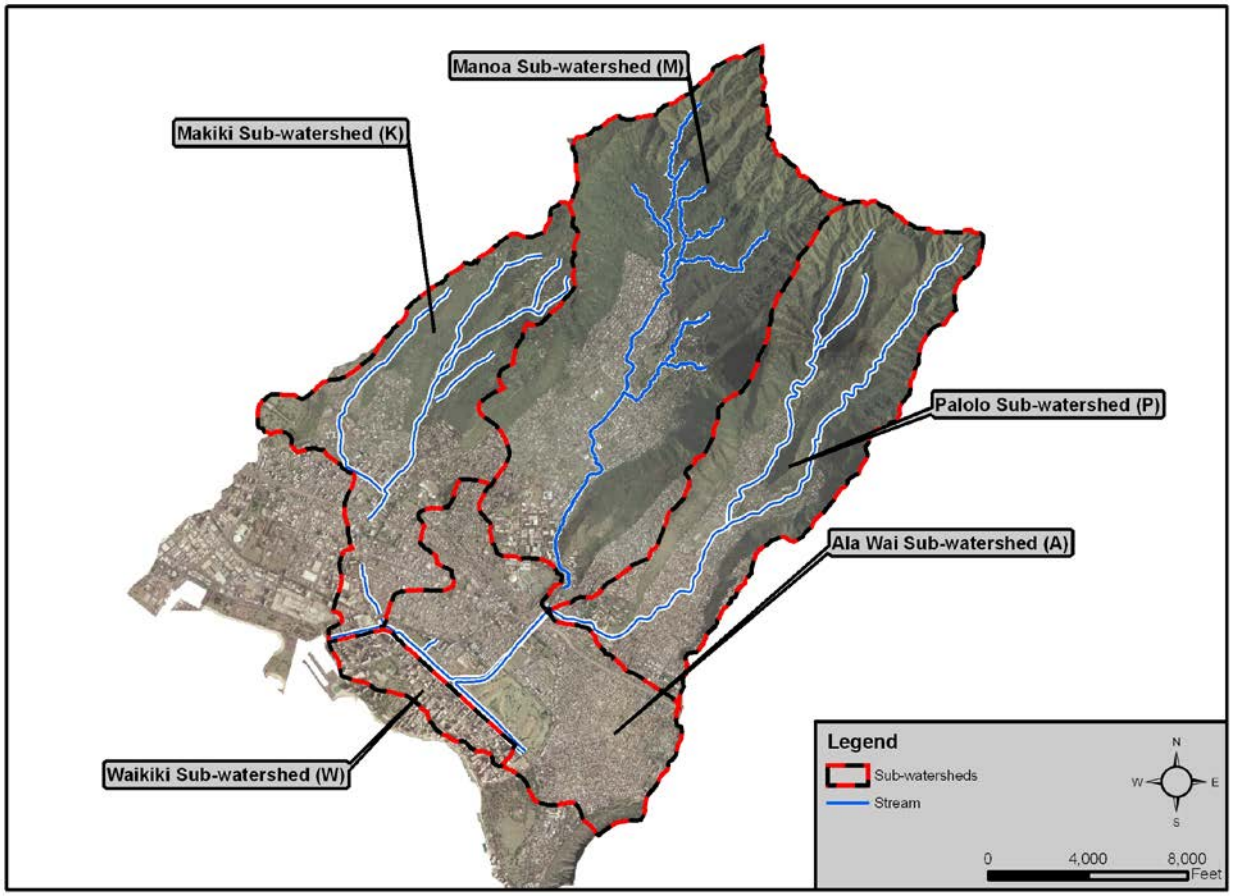

Figure 2-2. Major Streams and Sub-watersheds of Ala Wai Watershed

2.1.1 Climate and Flood Hydrology

Hawai'i's subtropical climate is governed by northeasterly trade winds that regulate weather patterns. The trade winds rise over the Ko'olau Mountain ridges, creating high moisture and orographic rainfall in the mountainous regions. These regions, such as the valley systems of Makiki and Mānoa typically receive more than 160 inches of annual rainfall, whereas the Pālolo valley system receives less annual rainfall (Giambelluca 1984). Generally, rainfall amount decreases as one moves down the valley systems to the southern coast of O'ahu, and so the low-lying areas of the Ala Wai Canal and Waikīkī receive about 30 inches of annual rainfall. The wet winter season occurs from October to April, and the dry summer season occurs from May to September. It should be noted that the three severe storms described for this study occurred in October, December, and March, during the wet winter season. Temperatures on O'ahu fluctuate according to the season, with the winter temperature averaging a high of 77 degrees Fahrenheit (°F) and a low of 64°F. In the summer, temperatures average a high of 81°F and a low of 70°F (National Weather Service, 2008).

Floods on Oahu, other than those generated by high ocean waves, are caused by high intensity rainfall. Most major rainstorms that bring flood-producing rainfall are caused by the non-trade wind or Kona wind conditions which occurred during the wet winter season. Rainstorms can bring intense local showers affecting a small area or can blanket the entire island with rain. High-intensity rainfall, small drainage-basin size, steep basin and stream slopes, and little channel storage, produce

floods that are flashy (Wong, 1994). Most drainage basins have rapid response to rainfall characterized by steep triangular hydrographs. Time to peak is usually less than 1 hour and even for large intense storms, the rise and recession of the flood hydrograph usually occurs with 6 hours.

2.1.2 Geology and Soils

The valleys and gulches forming the Ala Wai Watershed are incised into the Koʻolau Volcano. The Koolau lavas are divided into the Koʻolau Basalt and the Honolulu Volcanics. Both of these formations play an important role in the Ala Wai Watershed. The Koʻolau Basalt primarily consists of Pliocene aged shield stage tholeiitic basalt. The Honolulu Volcanics are composed of Pleistocene aged alkalic basalt, basanite, and nephelinite (Lagenheim and Clague, 1987). Holocene and Pleistocene sedimentary caprock is found at the seaward end of the watershed.

The rocks of the Koʻolau Basalt can be divided into three groups, lava flows (aʻa and pahoehoe), pyroclastic deposits, and dikes. The lava flows of the Koʻolau basalt are usually thin bedded with an average thickness of about ten feet (Wentworth and MacDonald, 1953). These beds are composed of aʻa and pahoehoe flows and pyroclastic deposits. Aʻa contains a solid central core between two gravely clinker layers. Pahoehoe flows are usually characterized by a smooth ropy texture. Pyroclastic deposits originate from explosive volcanism. They are composed of friable sand-like ash and indurated tuff deposits. Dikes are thin near vertical sheets of rock that intruded or squeezed into existing lava flows or pyroclastic deposits.

The Honolulu Volcanics erupted much later than the Koʻolau Basalt and overlay the deeply eroded Koʻolau Volcano and its associated alluvial deposits. In Ala Wai they are composed of lava flows and ash and tuff. The lava flows have flow structures similar to the Koʻolau Basalt. The pyroclastic deposits are characterized by easily erodable, sand-like ash and relatively soft and easily erodable tuff. The Sugar Loaf flow which outcrops in cliffs in the UH Quarry poured down from Sugar Loaf on the northwest side of Mānoa Valley and pushed the lower section of Mānoa Stream to the southeast.

The caprock is composed of a wedge of terrestrial and marine sediments. It forms a coastal plain about 8000 feet wide in the Ala Wai area. The caprock is over 1000 feet thick in the seaward areas of the watershed (Wentworth, 1951). Near the ocean, much of the caprock has been covered with artificial fill.

Mānoa and Pālolo valleys are deeply eroded amphitheater shaped valleys that was later backfilled with alluvium and Honolulu Volcanic deposits. The original valleys were probably "V" shaped but the alluvial and volcanic fill material has formed a broad, flat-bottomed valley. The valley fill material is weathered at the surface but despite the heavy rainfall is probably fresh and unweathered in the subsurface. The ridges and valley walls of Mānoa and Pālolo Valleys are generally composed of Koʻolau Basalt (In some areas Honolulu pyroclastics drape the walls). The layered flows of Koʻolau Basalt have eroded into steep weathered cliffs which facilitate rapid runoff. Dikes in the back of the valleys impound groundwater at high elevations which contributes to perennial streamflow.

The altitude within the watershed ranges from mean sea level along the coastal areas, to 40 feet near the confluence of Mānoa and Pālolo Streams, and approximately 2,400 feet in the mountains. Several soil groups are found in the Ala Wai Watershed. The Lualualei-fill land-Ewa association is a

well-drained soil that may be found in the lower elevations. These soils have fine textured or moderately fine-textured subsoil or underlying material. The upper watershed is comprised of rock land-stony steep land association. These soils are generally found on steep to precipitous lands and are well-drained to excessively drained (MacDonald et al. 1970).

2.2 Makiki Sub-Watershed

The Makiki sub-watershed is the westernmost of the Ala Wai Canal drainage sub-watersheds, and drains 1,850 acres or 2.89 square miles of land. Makiki Stream, which is approximately 3.5 miles long, drains the sub-watershed. The stream's tributaries include Kanahā Stream, the main tributary that connects to Makiki Stream via Kanahā Ditch (a long lateral channel of about 6,400 feet), Kānealole Stream, Moleka Stream, and Maunalaha Stream (Townscape 2003). The upper segment of the sub-watershed is in the Koʻolau Mountains and is bordered to the west by the Punchbowl Crater.

Whereas the upper sub-watershed is largely forested and undeveloped, the sub-watershed becomes more urbanized as one moves seaward. The upper Makiki sub-watershed has preservation land uses and is considered non-urbanized in this study. The lower Makiki sub-watershed includes the populated Makiki areas of Wilder Avenue, Mānoa Road, and McCully Street. The urbanized portion of the sub-watershed has residential and commercial land uses. Makiki Stream runoff from urban areas and minor streams ultimately discharges into the Ala Wai Canal between McCully Street and Kalākaua Avenue bridges.

2.3 Mānoa Sub-Watershed

Mānoa sub-watershed is located between the Makiki and Pālolo drainage sub-watersheds and drains 3,822 acres (5.97 square miles) of land from the Koʻolau Mountains to the confluence of Mānoa and Pālolo Streams. The upper sub-watershed has preservation land uses and is considered non-urban. In the upper sub-watershed area, several smaller tributaries feed into the Waihī and Waiakeakua Streams and flow into the Mānoa Stream. Mānoa Stream drains the sub-watershed. The Mānoa Stream passes by Noelani Elementary School, the University of Hawaiʻi at Mānoa (UHM) upper campus, and Kānewai Field, and finally meets the Pālolo Stream to form the Mānoa-Pālolo Canal.

Most of the ground surface in the upper sub-watershed is covered with primarily non-native forest, and the middle segment of the sub-watershed is highly urbanized. The natural path and the characteristics of the Mānoa Stream have been altered significantly. Urban culverts discharge storm runoff into the Mānoa Stream throughout the developed area.

2.4 Pālolo Sub-Watershed

The Pālolo drainage sub-watershed is the easternmost of the Ala Wai Canal drainage sub-watersheds, and drains 2,601 acres (4.07 square miles) of land. The Mānoa sub-watershed borders it to the west, and the Mauʻumae Ridge borders the sub-watershed to the east. The Pālolo sub-watershed drains the Koʻolau Mountains and extends down Pālolo Valley to Waiʻalae Avenue. For the purposes of this study, the upper Pālolo sub-watershed is considered non-urban because it has preservation land use. Pūkele Stream and Waiʻōmaʻo Stream are the sub-watershed's two tributary streams. These streams flow into the Pālolo Stream that drains mostly the urbanized portion of the sub-watershed. The land uses in this area are commercial and residential. The Pālolo Stream meets the Mānoa Stream as the Mānoa-Pālolo Canal. As the Pālolo Stream passes through the urban Pālolo area, the stream is a concrete-lined channel that was part of a flood control project constructed by the City and County of Honolulu.

2.5 Mānoa-Pālolo Canal Junctions

The Mānoa and Pālolo Streams meet as the Mānoa-Pālolo Canal downstream of Kānewai Field and immediately north of Waiʻalae Avenue. The Mānoa-Pālolo Canal discharges into the Ala Wai Canal downstream of the Ala Wai Golf Course. Even though Mānoa-Pālolo Canal drains a segment of the Ala Wai Canal sub-watershed, it does so through large storm drainage outfalls that empty directly into the canal. Thus, only junctions (not areas of the sub-watershed) of the Mānoa-Pālolo Canal were examined for this study, and the large outfalls that enter the canal drain 20,285 acres of land.

2.6 Ala Wai Canal Sub-Watershed

The Ala Wai Canal sub-watershed drainage system is 1805 acres (2.82 square miles) including the Mānoa-Pālolo Canal. Historically, the lower portion of Ala Wai Watershed consisted of wetlands and provided ample storage for heavy runoff from the watershed. Ala Wai Canal was designed to drain the wetlands formed by the streams and create dry land for Waikīkī resort development, and the canal was constructed in the 1920s. At the time of the Ala Wai Canal project, the urban development in the watershed was limited, but today the Waikīkī area is heavily urbanized. Runoff from Makiki, Mānoa, and Pālolo sub-watersheds contains suspended materials from the natural

reaches of these watersheds, and, as a result, Ala Wai Canal has experienced significant sedimentation over the years.

For the purpose of this study, the Ala Wai Canal was modeled as a reservoir using USACE's HEC-HMS. Considering that the canal may be subject to backflow and meets the ocean at mean sea level, a reservoir model is appropriate due to the low elevation and likelihood of water storage. This assumption significantly affected the modeling of the Ala Wai Canal.

2.7 Waikīkī Sub-Watershed

The Waikīkī drainage sub-watershed is the southern-most and coastal area of the Ala Wai Canal drainage sub-watersheds, and drains 298 acres (0.47 square miles) of coastal land. The Waikīkī area is heavily urbanized and not only a vital center of the tourism industry on Oʻahu but also a popular residential, shopping, and nightlife area. Historically, the Waikīkī area was swamp land, and thus the sub-watershed is low-lying. The sub-watershed is characterized by impervious surfaces, and storm drainage runoff either flows as overland flow, flows directly into the ocean, or flows through the City drainage system directly into the Ala Wai Canal. The canal is at a similar elevation as the Waikīkī sub-watershed itself.

3 Data Gathered

The character of the land, the historical rainfall data, and historical stream flow data are relevant to the hydrological analysis of the Ala Wai Watershed. Data used for HEC-HMS model calibration included rain gage data, stream flow gage data, stage gage data, and tide gage data records of historical storms, and field surveys. These data were used to create rainfall intensity-duration-frequency curves. Rainfall data were the input for the HEC-HMS rainfall-runoff model calibration.

3.1 Rain Gages

Data sets from thirteen rain gages were used for the Ala Wai Watershed hydrologic analysis. Four of these rain gages are operated by the National Weather Service (NWS), four rain gages are operated by the BWS, three rain gages are operated by USGS, one rain gage is operated by the UHM, and one rain gage is privately operated. The characteristics of each gage are listed in Table 3-1. Figure 3-1 maps these rain gages in or nearby the study area, labeled by their name and identification number (ID). As shown, rain gages are located in a diversity of elevations and locations throughout the greater Ala Wai Watershed.

Typically, rainfall in upper elevations of the sub-watersheds is greater than that of the lower elevations. For the Makiki sub-watershed, the rain gage at the highest elevation is the Tantalus Peak gage at 1,665 feet above mean sea level (MSL). The Mānoa Tunnel rain gage at 650 feet above MSL is the highest for the Mānoa sub-watershed, and the Pālolo Tunnel rain gage is located at 995 feet above MSL. The lowest rain gage for the entire Ala Wai watershed is the Waikīkī Zoo gage at about 5 feet above MSL. It should be noted that three rain gages were located outside the study area. The Waikīkī Zoo rain gage (717.2) was used to represent the Ala Wai Canal and Waikīkī sub-watersheds. The Wihelmina Rise rain gage (721) was used to represent the middle Pālolo sub-watershed, and the Punchbowl Crater rain gage (709) was used to represent the lower Makiki sub-watershed. Figure 3-2 shows the annual rainfall distribution in the Ala Wai Watershed by major sub-watersheds.

Rain gage data sets vary according to whether records are taken in real time (typically 15-minute intervals) or daily. Records were used to extrapolate the rainfall hyetographs for all the sub-watersheds in the calibration basin models. Also, rain gage records provided essential data for three storms that were used to calibrate the HEC-HMS model. Those storms occurred on December 17–18, 1967; October 30, 2004; and March 31, 2006.

3.2 Stream Flow Gages

Historic stream gage records were used to develop the sub-basin analyses for the HEC-HMS model. Data sets came from nine stream gages throughout the Ala Wai Watershed, and these gages are shown in Figure 3-3 labeled with their USGS identification number. Stream gage data for three storms were essential for calibrating the HEC-HMS model (see calibration discussion in Section 3.8). These three storms occurred in 1967, 2004, and 2006 and are discussed in Section 3.8. Stream gage data for these events are limited depending on whether the gages' record continuously, such as by 15-minute intervals, or whether they simply record peak flow values. The characteristics of the stream gages are given in Table 3-2, and the stream flow gages are shown in Figure 3-3.

3.3 Stage Gages

The Waikīkī and Ala Wai Canal sub-watersheds are located on low-lying coastal land, and data from two stage gages were used in these areas, as shown in Figure 3-4. Stage gage data was essential for calibrating the Ala Wai Canal sub-watershed model detailed in Section 4.6. The nearest stage gage in the ocean was the National Oceanic and Atmospheric Agency's (NOAA's) tide level station 1612340 at Honolulu Harbor, which was used to calibrate the model. The other gage used was USGS 16247130 at Ala Wai Elementary School. These stage gages are located west of the study area as shown in Figure 3-2. Although there are no public published stage records, the local USGS office provided Oceanit with continuous stage data for the October 30, 2004, storm for calibration purposes (see Section 4).

3.4 Drainage Systems

The City's municipal storm drainage system drains the sub-watersheds of the study area. Runoff from storms flows into the streams or drainage systems throughout the study area. The City's drainage maps were used to identify the locations of the existing storm drainage system. These maps provided information about the characteristics of drainage system segments, including whether the segments are natural or channelized and the size of outlets throughout the system. The drainage systems evaluation results were used in determining the sub-basins boundaries. For example, the boundaries of sub-basin K4 were mainly determined from drainage evaluation.

University of Hawai'i at Mānoa provided utility maps showing the drainage systems through the campus area. Existing conditions of the UHM's storm drainage system, such as the size of relevant culverts, were gathered from these maps. Detailed drainage systems information can be found in the *Final Drainage Evaluation Report Ala Wai Watershed Project* (Oceanit 2008a). The drainage systems information within the UHM upper campus was used to determine the boundaries of sub-basin M12. Based on this information, the boundaries of sub-basins M12 were changed slightly. As a result, this sub-watershed's drainage area was different from the Manoa Watershed Study—it changed from 0.672 to 0.749 square miles.

3.5 Geospatial Data

Geospatial information [1] and field survey observations were used to determine hydrologic conditions, such as terrain roughness characteristics and stream channel cross sections. Information collected included LiDAR data and aerial maps. Numerous field visits to the various sub-watersheds of the study area were made over the course of January 2008 until September 2008 to confirm and/or describe any relevant existing condition of a drainage system facility or the existing conditions in a sub-basin.

LiDAR data were inputted into ArcView GIS 3.3 with the HEC-GeoHMS 1.1 extension to create a geospatial model of the Ala Wai Watershed. The HEC-GeoHMS (USACE 2003) model was used to delineate the initial sub-watershed boundaries, calculate sub-watershed areas, and determine flow path lengths and slopes. However, the sub-watersheds within the study area were not completely delineated by the HEC-GeoHMS model alone. The existing drainage infrastructure and the locations of potential conceptual design measures were important factors for sub-watershed delineation. The final sub-watershed delineation was the result of a combination of the HEC-GeoHMS model, an evaluation of the existing storm drainage system, and the potential locations of the conceptual design measures. LiDAR data were used to approximate the boundaries of sub-basins and sub-watersheds. In addition, ArcView GIS 3.3 and drainage maps were used to determine the boundaries of urbanized areas of the sub-watersheds' drainage areas because better resolution was available for evaluation.

3.6 Sub-Basin Delineation

For the purposes of this study, sub-watershed refers to the larger watershed areas of Makiki, Mānoa, Pālolo, and Waikīkī, and the term "sub-basin" refers to the smaller sub-watersheds within these sub-watersheds. These terms are used to avoid confusion. Also the term "sub-basin" is commonly accepted for the HEC-HMS model delineation of small drainage areas. Sub-basins provide clear boundaries for hydrologic study, and sub-basins were delineated according to a couple of assumptions. The key assumption is that the City's drainage systems, the underground storm sewers, does not cross a topographic sub-basin boundary for all return periods from 2-year through 500-year storms.

This assumption takes into account all the storm runoff for storms, but not all storm runoff necessarily flows through storm drainage systems. According to the United States Department of Agriculture (1990; Module 206A), "Storm sewers generally handle only a small portion of a large event. The rest of the peak flow travels by street, lawns, and so on to the outlet." This suggests that

[1] The aerial images that were used for the hydrologic analysis are from the National Geospatial-Intelligence Agency (NGA) supplied by the USGS. The specifications for these images are 0.3 meter pixel size, rectified natural color image orthoimage. The working image was re-sampled to 1-meter pixel size.

The digital elevation LiDAR data used in this hydrologic analysis were obtained from AIRBORNE 1, with an accuracy of 4 elevation points per square meter. The original data were reprojected to North American Datum (NAD) 83 HARN 1993 Universal Transverse Mercator (UTM) Zone 4 meters. The grid size was 2 meters by 2 meters.

storm runoff flows along the natural geographic flow path and not necessarily through the storm drainage system. Based on the City's storm drainage standards, the drainage capacities with catchment areas greater than 100 acres should meet 100-year storm drainage standards; the drainage capacities with catchment areas equal to or less than 100 acres should meet 10-year storm drainage standards. Consequently, at junctions with contributing drainage systems, peak discharges may be lower than predicted. Similarly, at junctions where drainage system catchment areas are not considered, actual peak discharges may be higher than predicted.

Some delineations of sub-basins and assumptions about sub-basins were necessary for the low-lying areas of Mānoa-Pālolo Canal, Ala Wai Canal sub-watershed, and Waikīkī sub-watershed. Because Mānoa-Pālolo Canal receives drainage from other sub-watersheds with relatively large drainage systems, only the junctions in the Mānoa-Pālolo Canal were examined and there were no sub-basins delineated around the canal itself. Also, delineation for the Waikīkī sub-watershed was particularly problematic because some of its sub-basins drain directly into the ocean with a relatively small flow directed through the outfalls designated on the drainage maps.

It should be noted that all the hydrologic analysis results in this study for Mānoa sub-watershed were exactly the same as performed in the *Mānoa Watershed Project Final Hydrology Report* (Oceanit 2008b) to keep consistency with the previous Mānoa Watershed Project hydrologic study. Another assumption was made about the UHM area in the Mānoa sub-watershed. The drainage area of sub-watershed M12 (UHM upper campus) was changed from the previous 0.672 square miles (Oceanit 2008) to 0.747 square miles. This drainage area determination accounts for the contribution of a 96-inch culvert storm drainage system at Dole Street Bridge. The characteristics of the storm sewer network were collected from the UHM Utility Map (2008).

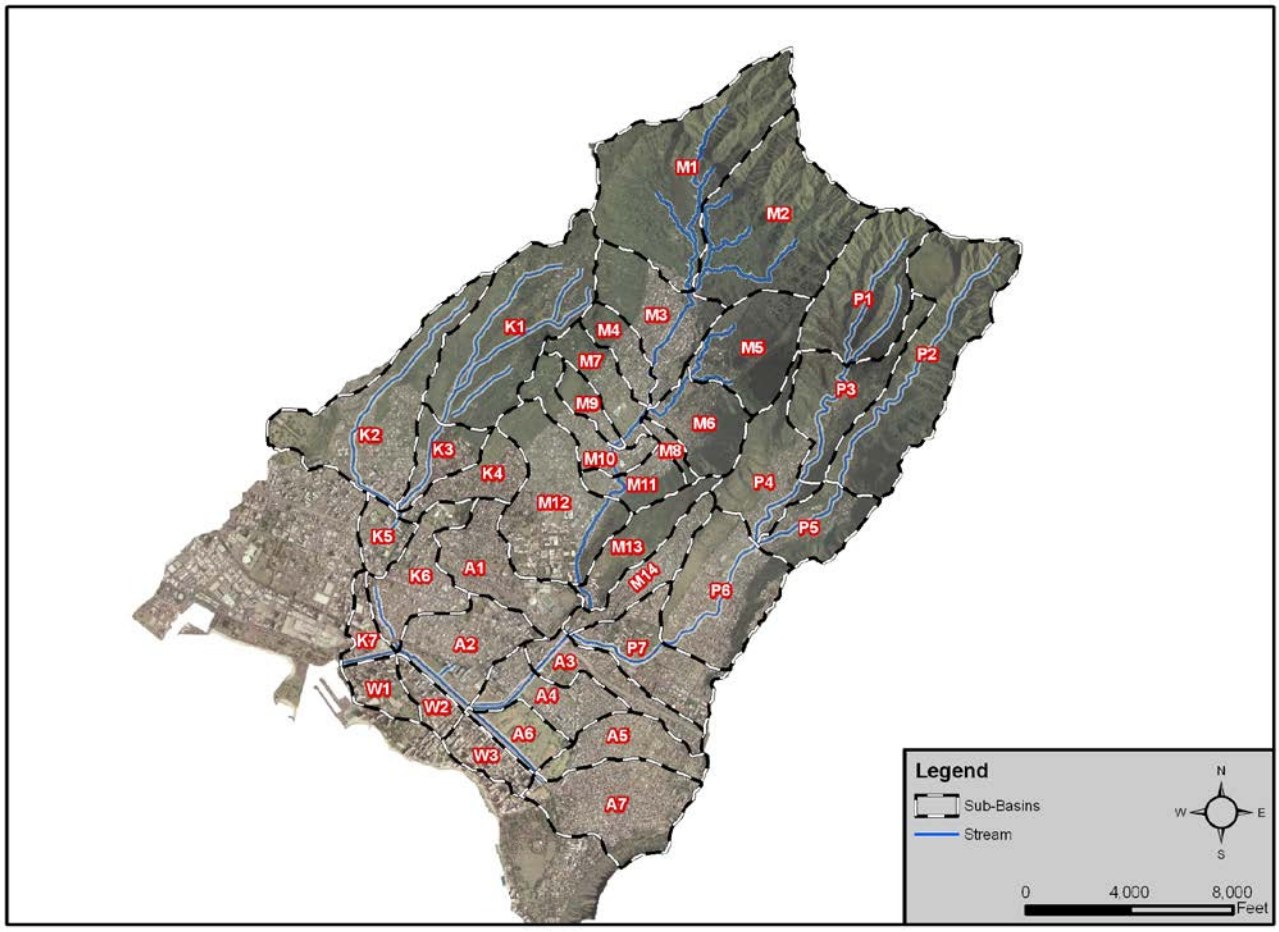

Figure 3-5. Ala Wai Watershed Sub-Basin Delineation

Ala Wai Watershed delineation of sub-basins was based on the junctions that are confluences of study area streams. The following table of sub-basin delineations designates the respective sub-watershed by the following.

- 'J' for junctions, or stream confluences, throughout the watershed
- 'K' for sub-basins in the Makiki sub-watershed
- 'M' for sub-basins in the Mānoa sub-watershed
- 'P' for sub-basins in the Pālolo sub-watershed
- Note that Mānoa-Pālolo Canal sub-watershed has junctions only and not sub-basins because other sub-basins empty into this canal but it does not drain its surrounding area
- 'A' for sub-basins in the Ala Wai sub-watershed; assumed to be a reservoir for the purposes of this study (see earlier discussion in Section 3.6)
- 'W' for sub-basins in the Waikīkī sub-watershed

Table 3-4 (Continued). Ala Wai Watershed Sub-Basin Delineation

Drainage systems collect the majority of runoff in Waikīkī, and thus, information about these systems was used to delineate the Waikīkī sub-watersheds. Most of the runoff flows through the City's drainage systems and discharges into the Ala Wai Canal. However, a small portion of runoff flows directly into the ocean. This small portion is overland flow or is emptied directly into the ocean by drainage pipes.

3.7 Storm Records Used for Calibration

Calibration of the HEC-HMS model relied on sub-basin analysis that used available records of three storms in December 17-18, 1967; October 30, 2004; and March 31, 2006. However, partial stream flow data were available for some gages and junctions had different recording equipment. Below is a list of the records available by location and storm. The locations refer to the HEC-HMS model layout.

- A partial data set from JM3 (Lowrey Ave. Bridge) from the 2004 storm was used for calibration
- At M2 (Waiakeakua sub-basin), peak flow data were used for the 1967 storm, and real-time data were used for the 2004 and 2006 storms
- At JMP2 (USGS stream gage 17247100 at Kaimukī High School), peak flow data were used for the 1967 storm, and real-time data were used for the 2004 and 2006 storms.
- At JP1 (USGS Pūkele Stream gage), peak flow data from the 1967 storm were used, and real-time data from the 2004 storm were used
- At JP3 (USGS stream gage 17247000 at Pālolo Stream), peak flow data from all three storms were used, but some of these data were discarded because they were clearly inaccurate—comparison to other gage readings downstream during the same storm showed clear inconsistencies

3.7.1 December 1967 Storm

On December 16, 1967, a surface weather front appeared to be stationary west of Hawai'i (DLNR 1968). Torrential rains started falling on O'ahu around the middle of the night on December 17. Many rainfall stations reported excessive rainfall during the storm. Pālolo Valley, Wai'alae-Kāhala, Niu Valley, and Waimānalo suffered extensive flood damage. Rainfall amounts registered in the windward area had a rainfall frequency of about a 25-year storm (DLNR, 1968). The Tantalus Peak rain gage registered 5 inches of rainfall for a 3-hour period ending at 3:00 AM. The Pālolo Tunnel rain gage, maintained by the BWS, recorded 10.06 inches between the middle of the night and 8:00 AM hours, with 2.4 inches from 4:00 AM to 5:00 AM. The rainfall intensity was almost uniformly distributed from the coastal area to the Ko'olau Mountains. The USGS stream gage 16247000 at the Pālolo Stream recorded a record high peak discharge of 4,270 cubic feet per second (cfs); the USGS stream gage 16247100 at the Mānoa-Pālolo Drainage Canal recorded its highest estimated discharge at 10,100 cfs.

3.7.2 October 2004 Storm

A storm on October 30, 2004, that caused flooding in the Mānoa Valley was characterized as about a 20-year storm (NWS 2005). This return period corresponds to a 5% probability of occurrence. The persistent and heavy rainfall created swift and high stream flows that were recorded throughout the Mānoa Stream by various rain and stream gages. The heaviest rainfall happened around 7:30 PM, at which time the Lyon Arboretum rain gage recorded 1.29 inches in 15 minutes. The gage records for the October 2004 storm were used to calibrate the HEC-HMS model.

3.7.3 March 2006 Storm

On March 31, 2006, a strong storm caused the NWS to issue flash flood warnings for O'ahu because rain fell on already saturated ground. The storm moved over the windward (eastern) half of O'ahu during the late morning, and rainfall of 1 to 2 inches were recorded within one-hour periods by several NWS gages (NWS 2006). The NWS Waimānalo rain gage recorded over 3 inches of rainfall within a two-hour period. During the six weeks prior to this storm, O'ahu had experienced heavy rains that saturated lands on the windward side of the island. The March 31 rainfall, coupled with the saturated character of the land, produced flash floods throughout the island (NWS 2006). The Moanalua, Makiki, and Mānoa Streams overtopped their banks, and residents of Mānoa valley were alerted of flash flooding in the area. Various intersections and flooding forced the partial closure of the area's major highway, H-1 Freeway, and downtown streets were clogged with traffic (Pacific Business News 2006).

4 Hydrologic Analysis Procedure

Hydrologic analysis of sub-watersheds of the Ala Wai Watershed utilized up to five hydrologic modeling methods. Given the HEC-HMS model layout for the Ala Wai Watershed, the hydrologic analyses for sub-watersheds were completed on the basis of the existing conditions—particularly whether or not sub-watersheds are urbanized. For the sub-watersheds without much urbanized area, hydrologic models were calibrated using the storm records outlined in Section 3.8. The hydrologic model, as shown in Figure 4-1 was based on the sub-watersheds delineated. These sub-watersheds include the upper Makiki, upper Mānoa, and upper Pālolo. Thus, Sections 4.2 through 4.5 outline the necessary parameters that were calculated: rainfall amount, time of concentration, and curve numbers. As mentioned earlier, the Clark Unit Hydrograph was used as the transform method for these areas that are not urbanized.

For the sub-watersheds with more urbanized area, the hydrologic models used the Kinematic Wave Transform Method. Section 4.7 provides the Kinematic Wave Transform Method analyses of the urbanized areas of the Ala Wai Canal and Waikīkī sub-watersheds, alongside the Mānoa-Pālolo Canal junctions considered.

4.1 Hydrologic Model Layout

Stream junctions of interest that are listed in Table 3-3 are illustrated as the final hydrologic model layout as shown below in Figure 4-1.

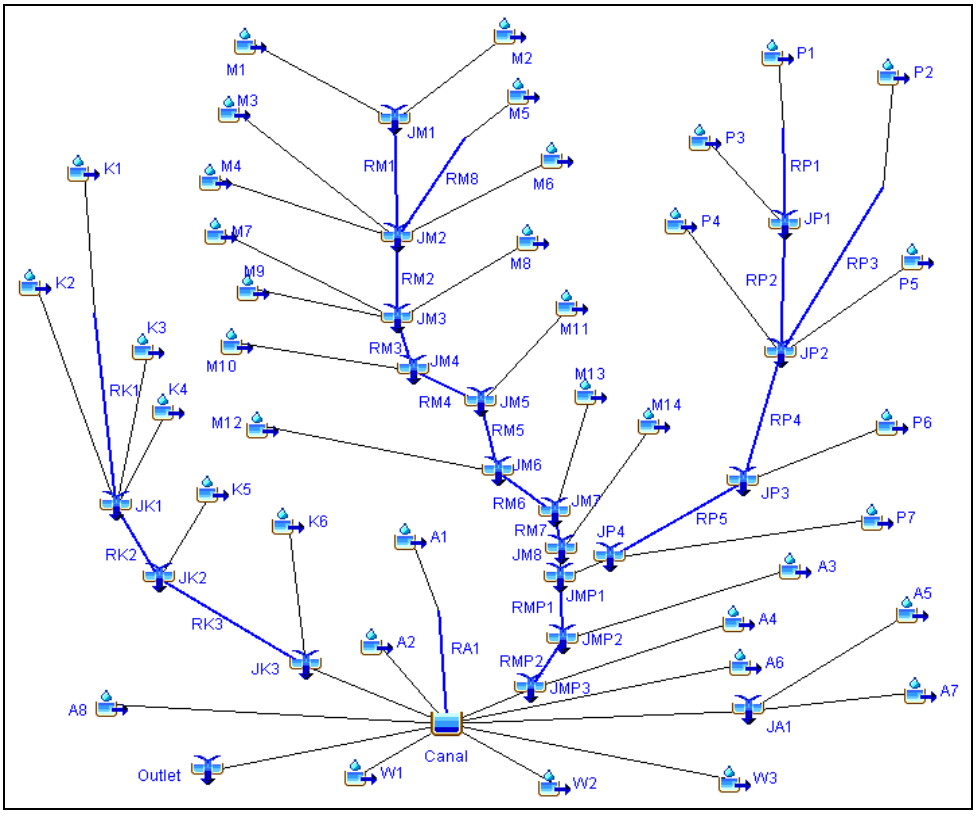

Figure 4-1. Ala Wai Watershed HEC-HMS Model Layout

4.2 Meteorological Model

The storm rainfall amounts that were the input for the hydrologic model are considered the meteorological model. The rainfall and stream flow data were collected from rain gage and stream flow gage records as available for the study area (see Sections 3.1 through 3.2).

4.2.1 Rainfall Amount Determination

Rainfall amount determination was necessary for 50, 20, 10, 5, 2, 1, 0.5, and 0.2 percent chance exceedance storms. These amounts were interpolated and/or extrapolated from "Rainfall Frequency Study for O'ahu", Report R-73, by Giambelluca, Lau, Fok and Schroeder (1984). For the 1-, 6-, and 24-hour rainfall amounts for the recurrence periods of 50, 10, 2, and 1 percent chance exceedance, values (shown in Table 4-1) were obtained directly from R-73 (Giambelluca 1984). The rainfall depths from R-73 were plotted, and the resulting smooth curve-function was used to estimate the rainfall depths that were not directly shown in R-73. Thus, for the percent chance exceedance storms less than the 1 percent storm, the rainfall amounts for various durations between 1 hour and 24 hours were determined from the duration nomographs presented in R-73. These curves are shown in Figure 4-3. The 0.5 and 0.2 percent chance exceedance storms' rainfall amounts were estimated by extrapolation using the rainfall depths relationships above the 1 percent chance exceedance storm. Rainfall values less than 1-hour were computed using 1-hour value. According to R-73, the 30-, 15-, and 5-minute rainfall values were determined by multiplying the 1-hour value by 0.714, 0.539, and 0.264, respectively.

Flow in the upper sub-watersheds may be underestimated due to sudden rainfall events that concentrate quickly as runoff because of high amounts of rainfall. Conversely, low rainfall is apparent in the lower sub-watersheds, and the relatively flat topography lends to underestimates of peak flows because runoff along the coastal areas may flow directly into the ocean. Thus, rainfall presented here is an average, based on the center point of the sub-basin and interpolated and extrapolated from the rainfall data available. The center point of each sub-basin was determined using the geospatial data discussed in Section 3.5. It should be noted that the 2001 Ala Wai Flood Study (USACE 2001) used a different approach for determining one rainfall value by averaging rainfall in the upper watershed and lower watershed rather than by averaging by the entire watershed.

Rainfall Intensity Duration Values for the Ala Wai Watershed

Percent Chance Exceedance	Recurrence Interval Year	Duration								
		5-min	15-min	30-min	1-hr	2-hr	3-hr	6-hr	12-hr	24-hr
50%	2	0.40	0.81	1.07	1.50	2.20	2.65	3.50	4.40	5.30
20%	5	0.49	1.00	1.32	1.85	2.80	3.40	4.45	5.70	7.15
10%	10	0.63	1.28	1.70	2.38	3.35	4.10	5.50	7.00	8.60
5%	20	0.70	1.43	1.89	2.65	3.80	4.65	6.25	8.05	10.05
2%	50	0.83	1.70	2.25	3.15	4.35	5.35	7.20	9.45	11.80
1%	100	0.91	1.86	2.46	3.45	4.85	6.00	8.25	10.90	13.65
0.5%	200	1.02	2.08	2.75	3.85	5.35	6.55	9.15	12.10	15.20
0.2%	500	1.16	2.37	3.14	4.40	6.10	7.55	10.40	13.65	17.00

Table 4-1. Determined Rainfall Intensity Duration Values in inches for Ala Wai Watershed, Oahu, Hawaii. Note: rainfall intensity frequency data determined from maps and nomographs in Giambelluca and others, 1984, DLNR Report R-73.

4.2.2 Rainfall Intensity-Duration-Frequency Curves

The rainfall-depth duration curves graph in Figure 4-2 shows the rainfall data as determined in average amounts for the percent chance exceedance storms. The rainfall amounts are for a 24-hour period, and were converted to intensity-duration-frequency (IDF) curves to offer rainfall intensities according to the range of storms examined (see Figure 4-3). The IDF curve is a crucial input into the HEC-HMS model analysis.

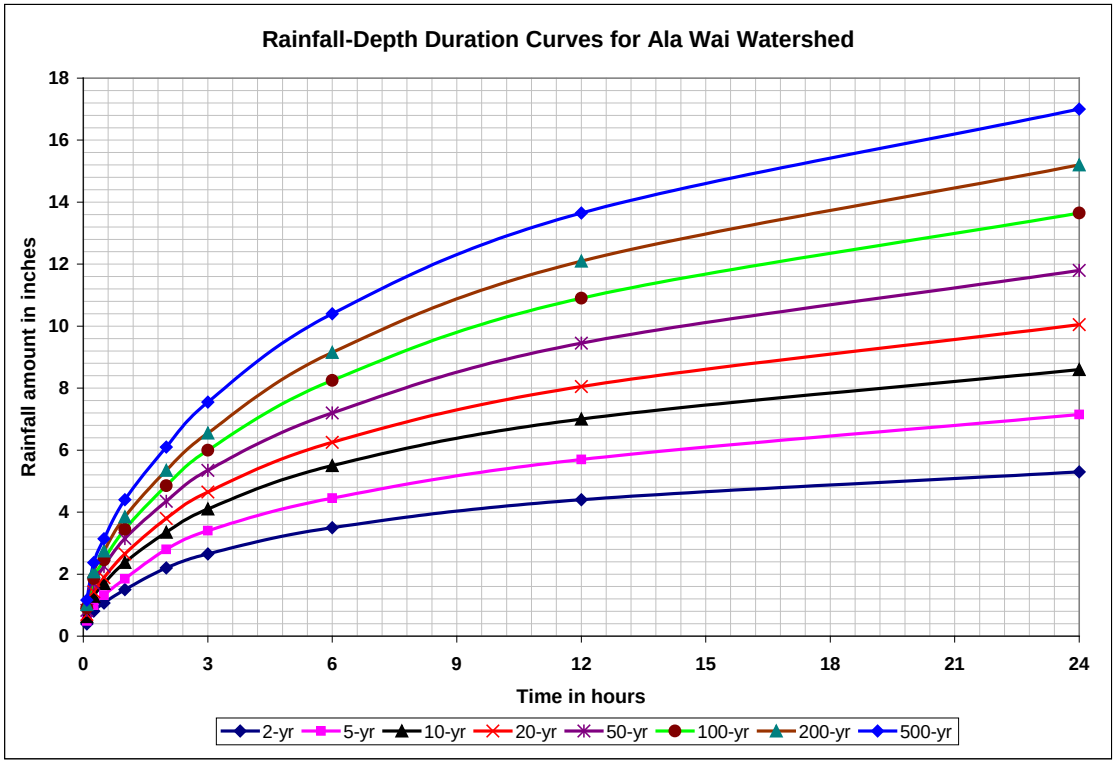

Figure 4-2. Rainfall-Depth Duration Curves for Ala Wai Watershed

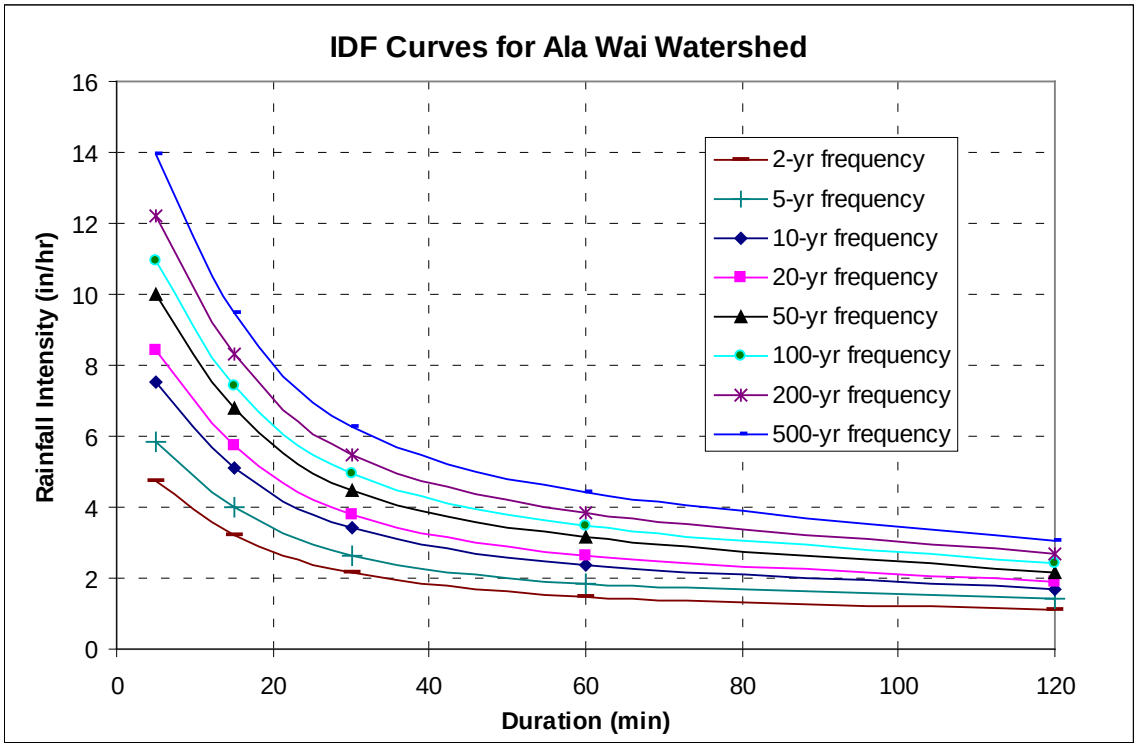

Figure 4-3. IDF curves for Ala Wai Watershed

4.2.3 Time of Concentration Calculation

The Clark Unit Hydrograph requires the parameter of the time of concentration (T_c) for each sub-basin. According to the TR-55 method, three types of flow path constitute the water flow: sheet flow, shallow concentrated flow, and channel flow; these three flows were added together to calculate time of concentration. According to the NRCS's Technical Report 55 (1986), "Time of concentration is the time for runoff to travel from the hydraulically most distant point of watershed to a point of interest within the watershed." The majority of the flow path may be channel flow as appropriate. Calculation of time of concentration is necessary for preparing the transform method for a unit hydrograph. The TR-55 velocity approach method was used to calculate time of concentration; that means the traveling time is a function of watercourse length and the velocity. The average velocity is a function of watercourse, slope, and type of channel.

A certain number of assumptions were made regarding sheet flow. The sheet flow segment describes the time period from raindrop impact until overland flow accumulates to a depth of about 0.1 foot, and one assumption made for time of concentration calculations was that the flow length for the stream reaches analyzed were not longer than 100 feet. The sheet flow segment T_c is calculated using Manning's kinematic solution, dependent on Manning's roughness coefficient *n*, the flow length, the rainfall amount, and the land slope. According to the SCS training material module 206A, "in most watersheds the overland [sheet] flow length is probably about 50 ft." (USDA, 1990) A maximum length of 100 feet is allowed in WinTR-55, and SCS suggests that a visit to the watershed is the best manner of determining the appropriate sheet flow length. Because this study lacked the appropriate observations for sheet flow during site visits, and considering previous studies and engineering judgement, a sheet flow length of 80 feet was set for all sub-watersheds in the Ala Wai Watershed for the calculation of time of concentration.

Overall, the flow length was determined from the City drainage maps and the known characteristics of the stream reach. Also, estimated flow length and land slope data were gathered from the geospatial data collected (see Section 3.5) using ArcView GIS 3.3. LiDAR topographic data and 5-foot elevation contours were used to calculate the slope of each sub-watershed.

4.2.4 Manning's *n* Roughness Coefficients

The surface Manning's roughness coefficients, based on the ground surface conditions, were determined as either 0.4 (woods with light underbrush) or 0.24 (dense grasses) using Table 3-1 from TR-55 (NRCS 1986). Where storm drainage systems are present in the sub-watershed, the appropriate flow path was used to estimate the time of concentration. Drainage pipe flow not under a pressure condition is treated as a portion of channel flow. The wetted perimeter condition assumes the full-flow condition for the drainage system pipes and the natural channel of the streambed. Altogether, the Manning's roughness coefficient for storm drainage facilities was selected as 0.015.

Table 4-2. TR-55 Method Time of Concentration Parameters

Table 4-2 shows the values for sheet flow, shallow concentrated flow, and channel flow that were used to calculate the times of concentration. The times of concentration range from 0.152 hours in the Mānoa 14 sub-basin to 0.313 hours in the Pālolo 2 sub-basin, as shown in Table 4-3.

4.3 Curve Numbers Calculation

Runoff curve numbers, according to the TR-55 method (NRCS 1986), were used to determine the loss method of the HEC-HMS. Soil types in the study area were identified, and assigned to their appropriate hydrologic soil group (HSG in Table 4-3) classification. Geospatial data collected were used to determine land cover appropriate to each sub-basin, and for the various sub-watersheds. The different types of land cover and associated curve numbers are shown in Table 4-3. For the specific sub-basins, curve numbers were multiplied by the areas of the soil types by sub-watershed. For each sub-watershed, the product of these calculations was averaged over the total sub-watershed area to arrive at a composite curve number.

Table 4-3 (Continued). Calculation of Composite Curve Numbers for Ala Wai Watershed

4.4 Mānoa-Pālolo Model Calibration

The final HEC-HMS model for the Ala Wai Watershed consisted of 38 sub-basins. The model used the SCS runoff curve number method as the loss method to be consistent with the previous Mānoa Watershed Project hydrologic study. The model for the Ala Wai Watershed used the Clark Unit Hydrograph as the transform method for the sub-basins that are not fully urbanized. The Clark Unit Hydrograph was used as the transform method for the sub-basins in Makiki Valley (K1-K4), Mānoa Valley (M1 to M14), and Pālolo Valley (P1 to P7). The urbanized sub-basins of lower Makiki, Ala Wai Canal, and Waikīkī applied the Kinematic Wave Transform Method. Because there are insufficient rainfall and stream flow data in the low-lying areas of the Ala Wai Watershed, it was difficult to calibrate the sub-basin parameters within in the Ala Wai Canal and Waikīkī sub-watersheds. Most of the parameters of the Kinematic Wave Transform Method were based on physical measurements; it is assumed that the peak discharges of the urbanized sub-basins are correct. The actual calibration models are those of Mānoa and Pālolo valleys (Section 4.4), a pilot calibration model for Makiki valley (Section 4.5), and a reservoir calibration model for Ala Wai Canal (Section 4.7). This last model represents the calibration for the entire watershed. Figure 4-4 shows the calibration model layout for the Manoa-Palolo valleys.

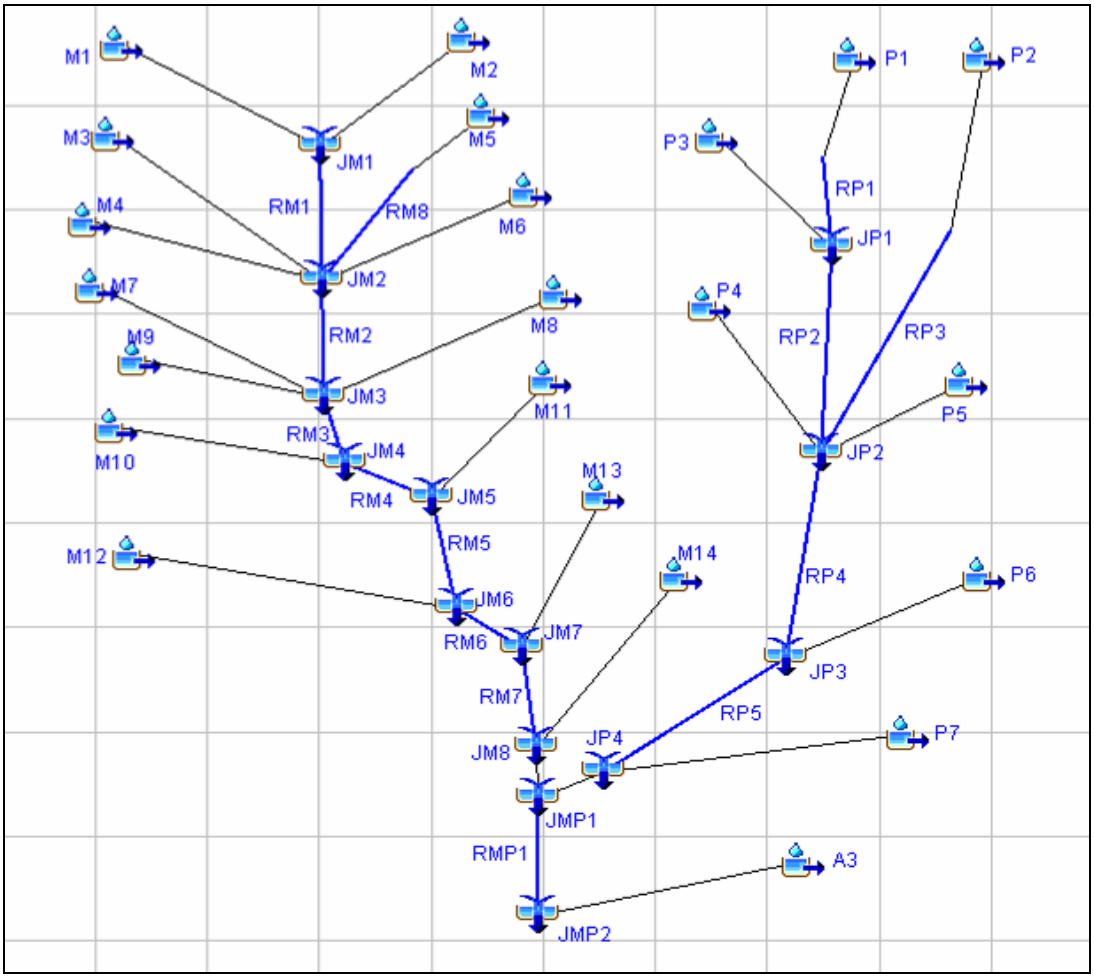

Figure 4-4. HEC-HMS Mānoa-Pālolo Calibration Model Layout

4.4.1 October 2004 Storm Calibration for Mānoa-Pālolo Area

The calibration for the storm of October 30, 2004, was based on the method used in the previous Mānoa Watershed Project hydrologic study. The calibration parameters used for the Mānoa sub-watershed in the Mānoa Watershed Project hydrologic study were used for the HEC-HMS model in the Ala Wai Watershed hydrologic study. The gage weights for sub-basins in Mānoa valley were the same as those used in the Mānoa Watershed Project described earlier. The main task of the calibration for the Ala Wai Watershed hydrologic study focused on the Pālolo sub-watershed and the area downstream of Kānewai Field gage, to the USGS stream gage 16247100. This stream gage is located on Kaimukī High School and had full stream flow records for the event. Gage weights were used for calibration purposes. The Thiessen polygon method was initially applied to determine the gage weight for each sub-basin. Figure 4-5 shows the Thiessen polygons for the October 2004 storm for the Ala Wai Watershed. The Thiessen polygon method does not account for orthographic rainfall effect in mountain areas. After taking into consideration the rainfall pattern, data quality, and storm movement and distribution, the final gage weights and relevant 24-hour rainfall of the October 2004 storm for each sub-basin were determined as shown in Table 4-4. (Note: 'MP' is used to abbreviate the Mānoa-Pālolo area.)

Table 4-4. Meteorological Model: Gage Weights for October 30, 2004, Storm for MP

The HEC-HMS meteorological model's parameters were calibrated using the October 30, 2004, storm data. Table 4-5 lists the final parameters for the HEC-HMS model in the Mānoa and Pālolo sub-watersheds. The parameters of the calibrated times of concentration are close to those calculated using the TR-55 method. The meteorological model used storm hydrographs for calibration and frequency based rainfall to compute the synthetic flood events.

Table 4-5. Calibrated Model Parameters for October 2004 Storm for MP

At junctions JP1 and JMP2, the observed rainfall from the October 2004 storm and the modeled stream flows are shown in Figures 4-6 and 4-7. The modeled peak flows occur slightly after the observed peak flows; and the peak flow for junction JP1, Pūkele Stream gage, was modeled at a higher amount than the observed peak flow in 2004. The time of concentration values may be too high in this case. For the October 2004 storm, real-time data from M2, partial data from JM3, partial real-time data from JM7, real-time data from JP1, peak flow data from JP3, and continuous data from JMP2 were used. Because the HEC-HMS model was calibrated using the October 2004 storm

data in the Mānoa Watershed Project hydrologic study (Oceanit 2008), the parameters for all Mānoa sub-basins except M14 in the Ala Wai Watershed hydrologic study were kept the same as they were in the Mānoa Watershed Project study.

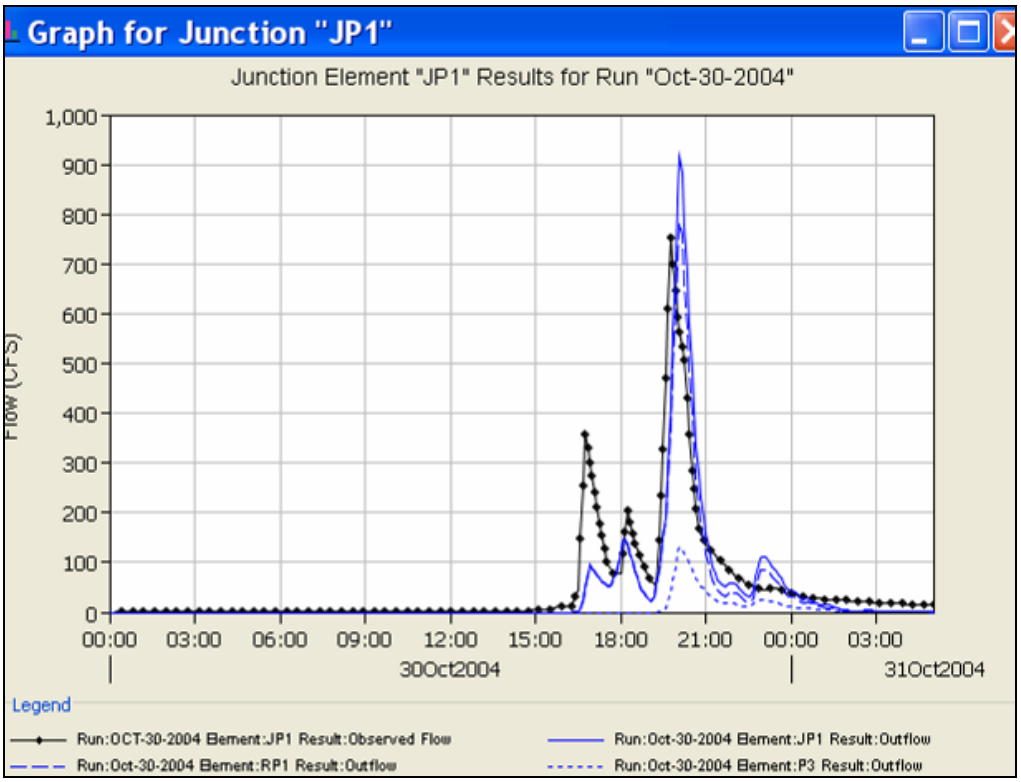

Figure 4-6. Observed and Modeled Stream Flows at Junction JP1 (Pūkele Gage [2440]) October 2004 Storm [calibration parameters: Simulated peak flow=775 cfs; observed peak flow=753 cfs; percent difference of peak discharge=2.9; percent difference of runoff volume=-15.4; peak-weighted root mean square error=96.6 cfs; Nash-Sutcliffe efficiency coefficient=0.256]

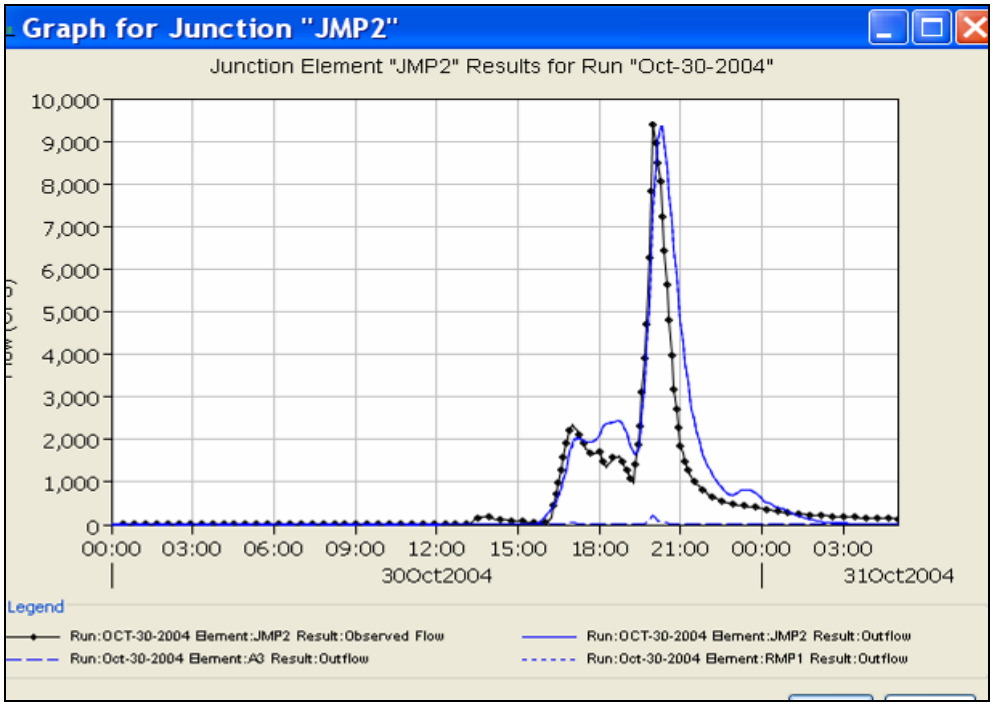

Figure 4-7. Observed and Modeled Flows at Junction JMP2 (Mānoa-Pālolo Gage [2471]) October 2004 Storm [calibration parameters: Simulated peak discharge=9,670 cfs; observed peak discharge=9,380 cfs; percent difference of peak discharge=3.1; percent difference of runoff volume=-24.6; peak-weighted root mean square error=571.2 cfs; Nash-Sutcliffe efficiency coefficient=0.826]

4.4.2 December 1967 Storm Calibration for Mānoa-Pālolo Area

The calibration for the storm of December 17–18, 1967, was based on the method used in the previous Mānoa Watershed Project hydrologic study. The calibration parameters in the Mānoa Watershed Project study for the Mānoa sub-watershed were not changed. The gage weights for sub-basins in the Mānoa sub-watershed were the same as that in the Mānoa Watershed Project study. The Thiessen polygon method was initially applied to determine the gage weight for each sub-basin. Figure 4-8 shows the Thiessen polygons for the December 1967 storm for the Ala Wai Watershed. After taking into consideration the rainfall pattern, data quality, and storm movement and distribution, the final gage weights and relevant 24-hour rainfall of the December 1967 storm for each sub-basin were determined as shown in Table 4-6. (Note: 'MP' is used to abbreviate the Mānoa-Pālolo area.)

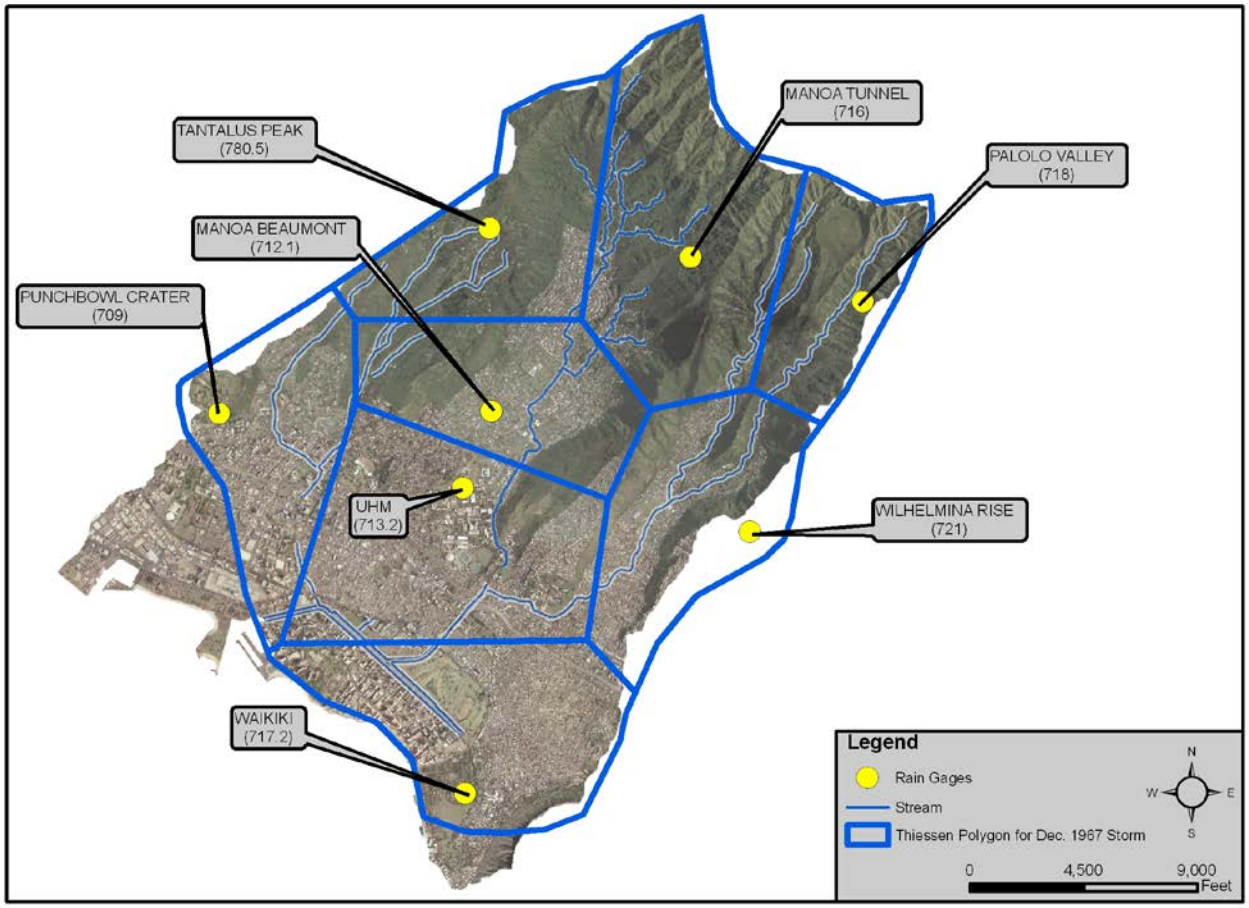

Figure 4-8. Rain Gages and Thiessen Polygons for December 1967 Storm for MP

The gage weights for the December 1967 storm, shown in Table 4-6, were calculated by considering the Thiessen polygons shown in Figure 4-8, the rainfall pattern, and the storm movement and distribution.

Meteorological Model: Gage Weights for December 17–18, 1967, Storm for MP

P7			0.45		0.1	0.15	0.3	9.18

Table 4-6. Meteorological Model: Gage Weights for December 17–18, 1967, Storm for MP

The meteorological model used storm hydrographs for calibration and frequency based rainfall to compute the synthetic flood events. For creating the peak discharges for various return periods, the frequency storm with an intensity position at 50% was used in computing the peaks and hydrographs. Table 4-7 lists the final parameters for the HEC-HMS model in the Mānoa and Pālolo sub-watersheds. The parameters of the calibrated time of concentrations are close to those calculated using the TR-55 method. At junctions JP1, JP3, and JMP2, the modeled stream flows for the December 1967 storm show a series of stream flow peaks as shown in Figures 4-9 to 4-11. For the December 1967 storm, peak flow data from M2, data from JP1, peak flow data from JP3, and continuous data from JMP2 were used.

	Loss Method --- SCS Curve Number		Transform--Clark Unit Hydrograph

4.4.3 March 2006 Storm Calibration for Mānoa-Pālolo Area

The Thiessen polygon method was initially applied to determine the gage weight. Figure 4-12 shows the Thiessen polygons for the March 31, 2006, storm for the Ala Wai Watershed. After taking into consideration the rainfall pattern, data quality, and storm movement and distribution, the final gage weights and relevant 24-hour rainfall of the March 2006 storm for each sub-basin were determined as shown in Table 4-8. The March 31, 2006, storm is a significant example because the storm produced a small amount of rain that generated a large amount of runoff because the soils in the study area were already saturated from six weeks of heavy rains. (Note: 'MP' is used to abbreviate the Mānoa-Pālolo area.)

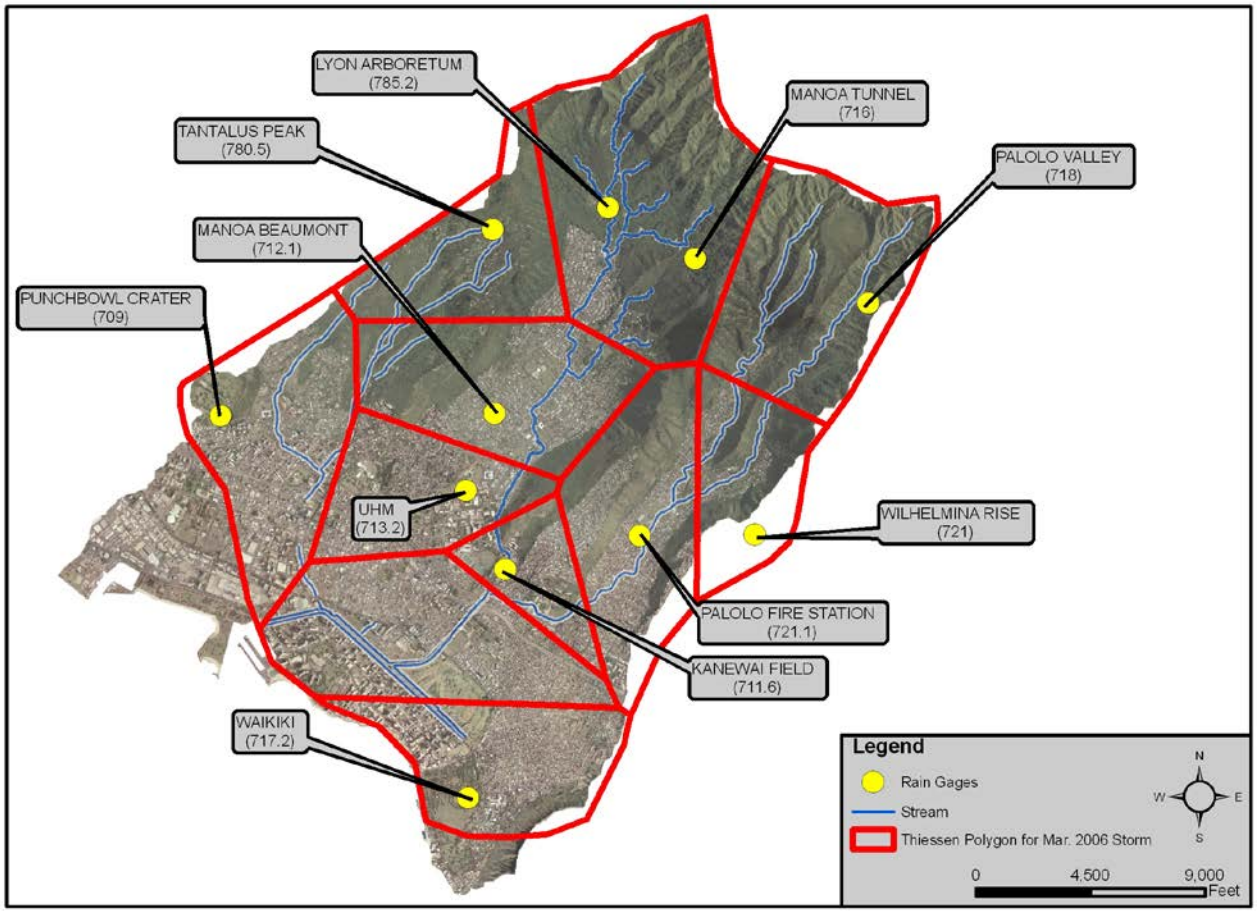

Figure 4-12. Rain Gages and Thiessen Polygons for March 2006 Storm for MP

Table 4-8. Meteorological Model: Gage Weights for March 2006 Storm for MP

The HEC-HMS meteorological model's parameters were calibrated using the March 31, 2006, storm data. Table 4-9 lists the final parameters for the HEC-HMS model in the Mānoa and Pālolo sub-watersheds. The parameters of the calibrated time of concentrations are close to those calculated using the TR-55 method. The meteorological model used storm hydrographs for calibration and frequency based rainfall to compute the synthetic flood events.

P7	0	90	0.10	0.10

Table 4-9. Calibrated Model Parameters for March 2006 Storm

The modeled stream flow for the March 2006 storm in M2 and at JMP2 show a small flow peak flow followed by a higher peak flow, as shown in Figures 4-13 and 4-14. The modeled peak flows are higher and earlier than the observed flows; however, the highest peaks match well. Due to the extremely saturated soil within the study area during this storm, the sub-basins' curve numbers were allowed to change to match the peak at JMP2 for calibration.

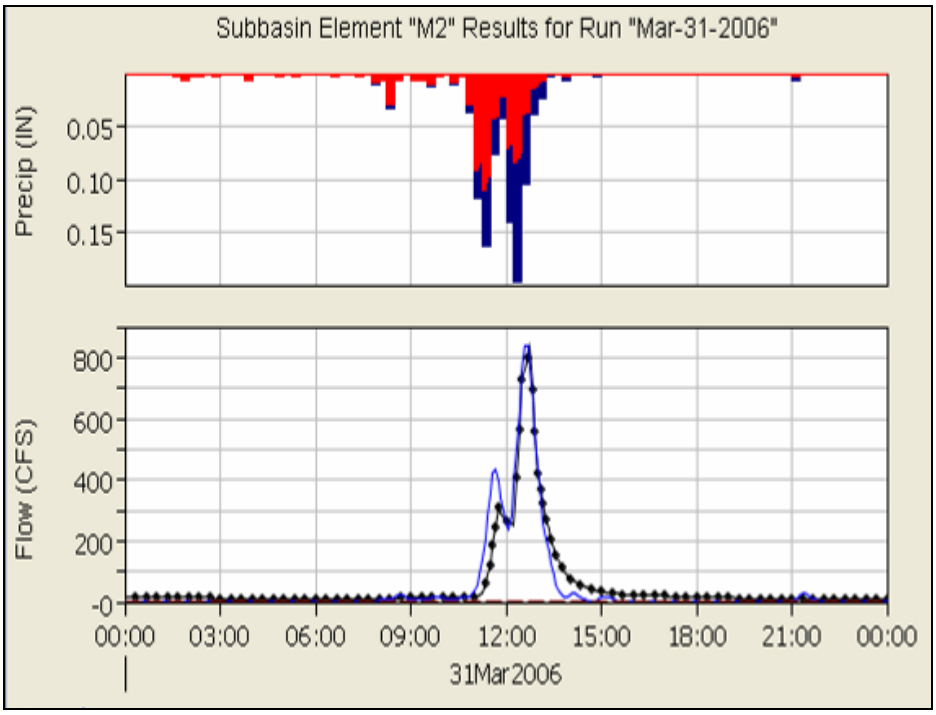

Figure 4-13. Observed and Modeled Stream Flows at Waiakeakua Stream (Sub-basin M2), March 2006 Storm [calibration parameters: Simulated peak discharge=837 cfs; observed peak discharge=832 cfs; percent difference of peak discharge=0.6; percent difference of runoff volume=-8.7; peak-weighted root mean square error=36.2 cfs; Nash-Sutcliffe efficiency coefficient=0.914]

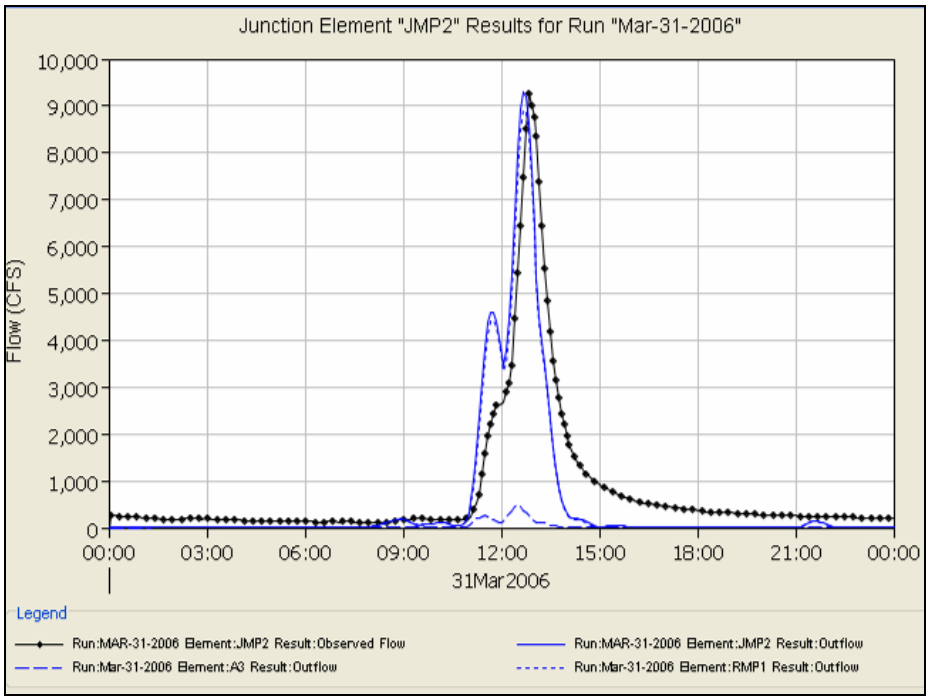

Figure 4-14. Observed and Modeled Stream Flows at JMP2 (USGS Stream Gage [16247100]), March 2006 Storm [calibration parameters: Simulated peak discharge=9,200 cfs; observed peak discharge=9,260cfs; percent difference of peak discharge=-0.7; percent difference of runoff volume=-28.6; peak-weighted root mean square error=734.2 cfs; Nash-Sutcliffe efficiency coefficient=0.776]

4.4.4 Final Loss and Transform Parameters for Mānoa-Pālolo Area

The loss method was determined by using the NRCS runoff CN method to take advantage of the results from the Mānoa Watershed Project hydrologic study. The parameters of initial abstraction were optimized for the Waiakeakua sub-basin and then were assigned to all the other sub-basins. Impervious parameters were set to zero because the percentage of the sub-basin that is impervious is specified in the CN. The optimization was used in each individual calibration (see Section 4.2). The final model parameters were the weighted average ones.

There is more confidence with the storms of October 30, 2004, and December 17–18, 1967, and less confidence with the storm of March 31, 2006. More weighting values were given to the calibrated parameters of the storm events of October 2004 and December 1967. The calibrated parameters of the October 2004 and December 1967 storm events were assigned twice the weight of the calibrated parameters for the March 31, 2006, storm. The finalized calibrated parameters of the HEC-HMS model were weighted as (2*2004 + 2*1967 + 1* 2006)/5. The weighted averaged loss method and transform method parameters for the Mānoa-Pālolo area are listed in Tables 4-10 and 4-11.

Note: T_c is the time of concentration, S_c is the storage coefficient

4.5 Makiki Model Calibration

Data from the USGS Makiki Stream Gage (16238000) at King Street Bridge was used to calibrate the Makiki HEC-HMS model. This gage measured two peaks in 2004. One peak was 487 cfs recorded on February 28, 2004, and the other peak was 1,000 cfs recorded on October 30, 2004. There were no sufficient rainfall data for February 28, 2004, so the 1,000 cfs peak on October 30, 2004, was used to calibrate the Makiki HEC-HMS model. The Thiessen polygons for October 30, 2004, in the Makiki sub-watershed can be seen in Figure 4-15, and they are the same as those for the Mānoa-Pālolo calibration of the October 30, 2004 storm. Because there was no timing rainfall gage within the Makiki sub-watershed, the Lyon Arboretum rainfall gage (785.2) was selected as the time weight gage for all sub-basins in the sub-watershed (see Table 3.1 for rainfall gage information). (Note: 'K' is used to abbreviate for the Makiki sub-watershed.)

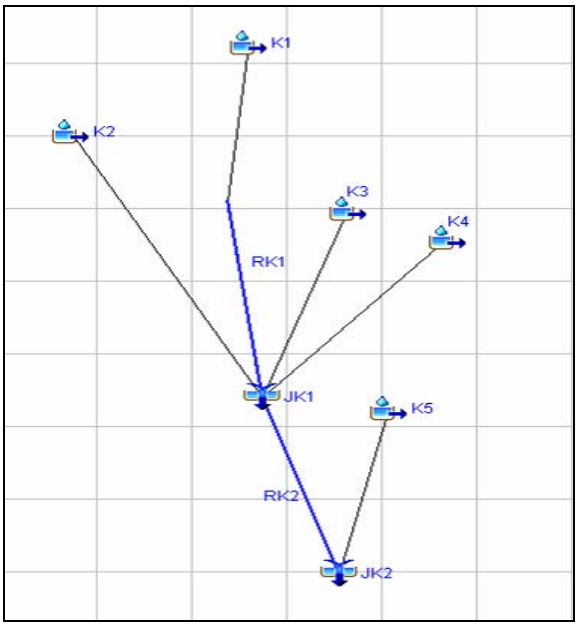

Figure 4-15. HEC-HMS Makiki Sub-Watershed Calibration Model Layout

4.5.1 October 2004 Storm Calibration for the Makiki Sub-Watershed

Due to the limited data available for the Makiki sub-watershed, the October 30, 2004, storm data were the only storm data used to calibrate the Makiki meteorological model. The calibration was based on the peak discharge of 1,000 cfs at King Street Bridge (USGS stream gage 16238000). Figure 4-5 shows the Thiessen polygons for the October 2004 storm for the Ala Wai Watershed. The Thiessen polygon method does not account for orthographic rainfall effect in mountain areas. The rainfall pattern, data quality, and storm movement and distribution were taken into consideration for the final gage weights. For the Makiki sub-watershed, the final gage weights for the 24-hour rainfall of the October 2004 storm were calculated and are given in Table 4-12.

Gage Weights for Makiki Sub-Watershed October 30, 2004, Storm						
Gage Weights	Thiessen Polygons (Gages in red recorded)

Table 4-12. Gage Weights for October 2004 Storm Makiki Sub-Watershed

The HEC-HMS meteorological model's parameters were calibrated using the October 30, 2004, storm data for the Makiki sub-watershed. Table 4-13 lists the calibrated parameters for the HEC-HMS model in the Makiki sub-watershed. The parameters of the calibrated times of concentration are close to those calculated using the TR-55 method. The meteorological model used storm hydrographs for calibration and frequency-based rainfall to compute the synthetic flood events. The final model parameters for the Makiki sub-watershed are given in Table 4-14.

Sub-basin	Initial Loss (inch)	Curve Number	Time of Concentration (hour)	Storage Coefficient (hour)
K1	1	42	0.18	0.45
K2	1	62	0.23	0.25
K3	1	68	0.12	0.2
K4	1	68	0.12	0.25
K5 (Plane 1)	0.7	85		
K5 (Plane 2)	0.1	98		

Table 4-13. Calibrated Parameters of Makiki Sub-Watershed

Sub-basin	Initial Loss (inch)	Curve Number	Time of Concentration (hour)	Storage Coefficient (hour)
K1	1	42	0.18	0.45
K2	1	62	0.23	0.35
K3	1	68	0.12	0.32
K4	1	68	0.12	0.35
K5 (Plane 1)	0.7	85		
K5 (Plane 2)	0.1	98		

Table 4-14. Finalized Parameters in HEC-HMS Model Makiki Sub-Watershed

The calibrated and final parameters of the HEC-HMS Model for the Makiki sub-watershed only differ by a few storage coefficients. These differences are due to the differing use and character of land in upper versus lower Makiki. The land use of the upper Makiki sub-watershed, a natural area with preservation land use, is similar to those of the upper Mānoa and Pālolo sub-watersheds. This similarity is reflected in the storage coefficient calculated. That is, the calibrated Clark Unit Hydrograph storage coefficient of the K1 sub-basin is 0.45 hour (hr), as shown in Tables 4-13 and 4-14, and the calibrated Clark Unit Hydrograph storage coefficients of sub-basins M5, P2, and M2, are 0.50, 0.32, and 0.57 hr respectively. In contrast, for lower Makiki sub-basins of K2, K3, and K4, the storage coefficients were increased slightly to match the calibrated storage coefficients in the Mānoa and Pālolo sub-watersheds. Figure 4-16 shows the modeled stream flows for JK2.

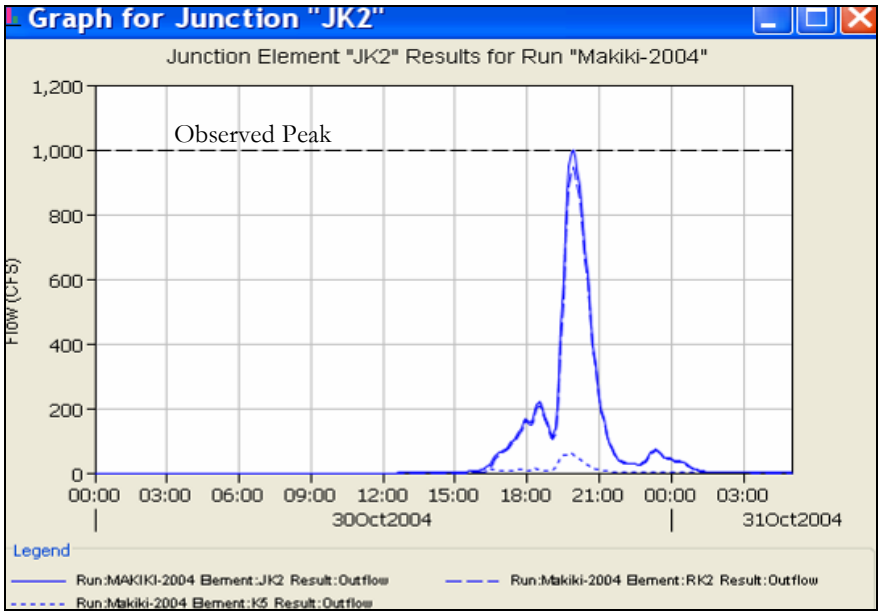

Figure 4-16. Modeled Stream Flows at JK2 (King Street Bridge, USGS stream gage 16238000) [Simulated peak discharge =1,000 cfs; observed peak discharge=1,000 cfs]

4.6 Kinematic Wave Transform Method Parameters

The Kinematic Wave Transform Method was used for the urbanized sub-basins. The Kinematic Wave technique is widely accepted for use in urbanized runoff modeling (USACE, 2001) because the parameters for various elements constituting the model are directly related to measurable, physical basin features. Parameters such as storm drain catchment length, drainage area, roughness, slope, and channel geometry are used to define the flow of water over basin surfaces into the stream channel. For the urbanized sub-basins, two overland flow plane elements were used to represent pervious land areas such as lawns and gardens and impervious areas such as streets and roofs. In this study, a sub-basin was modeled by combining two overland planes, a collector channel, and a main channel. The lengths, slopes, and roughness coefficients of the overland flow planes were based on the average of several values within the sub-watershed. Table 4-15 lists the values of the flow planes. Urbanized watersheds typically have various storm drainage systems, man-made channels, and natural channels. To model complex urban systems in a manageable fashion, the concept of typical collector channels was employed. The collector system was formulated from average parameters, in the sub-watershed. Tables 4-16 and 4-17 summarize the values of the collector channels and main channels.

In order to use the composite runoff curve number in a kinematic wave model, the sub-watershed must be divided into its pervious and impervious components. A curve number of 98 was used for the impervious areas (USACE 1973). The following equation can be applied to calculate the adjusted pervious curve number. The adjusted pervious curve number was used as the loss rate for the pervious areas.

$$X = \frac{CNc - 98 \times f}{1 - f}$$

Where $X = Adjusted\ \ pervious\ curve\ number$

$CNc = Composite\ curve\ number$

$f = total\ \ percent\ impervious, 0 \le f \le 1$

4.7 Reservoir and Reach Modeling

A number of assumptions were made during hydrologic modeling using the HEC-HMS method. These assumptions were made regarding the reservoir, reach, and junction modeling for the Ala Wai Watershed study area. Building upon the other sub-watershed model calibration, this final model represents the calibration of the entire watershed.

4.7.1 Ala Wai Canal as Reservoir

In order to consider backwater effect caused by the ocean tides, the Ala Wai Canal was modeled as a reservoir by assuming there is an imaginary boundary between the mouth of Canal and the ocean. "A reservoir is an element with one or more inflow and one computed outflow and is modeled by the assumption that water surface in the reservoir is level" (USACE 2008). The routing method was selected as the outflow structure. The size and type of imaginary outlet structure were mainly selected based on the cross section at the mouth of Ala Wai Canal. Noda and Associates (1994) study showed that the channel is a rectangular shape with a dimension of 152 feet x 14 feet near Ala Moana Bridge. The GeoRAS model also created similar cross sections at the mouth of the canal. The inlet elevation for this outlet structure was selected as -6.2 feet which was obtained from the October 30, 2004 storm calibration; then the rise of structure should be about 8 ft. The span of the structure was selected as 152 ft to match the field measurement. Figure 4-17 lists the reservoir model settings and Figure 4-18 shows its related outflow structure. There is no tide gage at the Ala Wai Canal mouth, the tide gage in Honolulu Harbor (NOAA tide level station 1612340) was used to represent the tail water effect. Consequently, the specified stage method was used to represent the main tail water. The elevation-storage function for the reservoir (Ala Wai Canal) was estimated by applying the bathymetric survey data for Ala Wai Canal conducted by Oceanit (2008c) and the LiDAR data for surrounding areas, as show in Table 4-18 and Figure 4-18.

Table 4-18. Elevation-Storage Curve Function Data

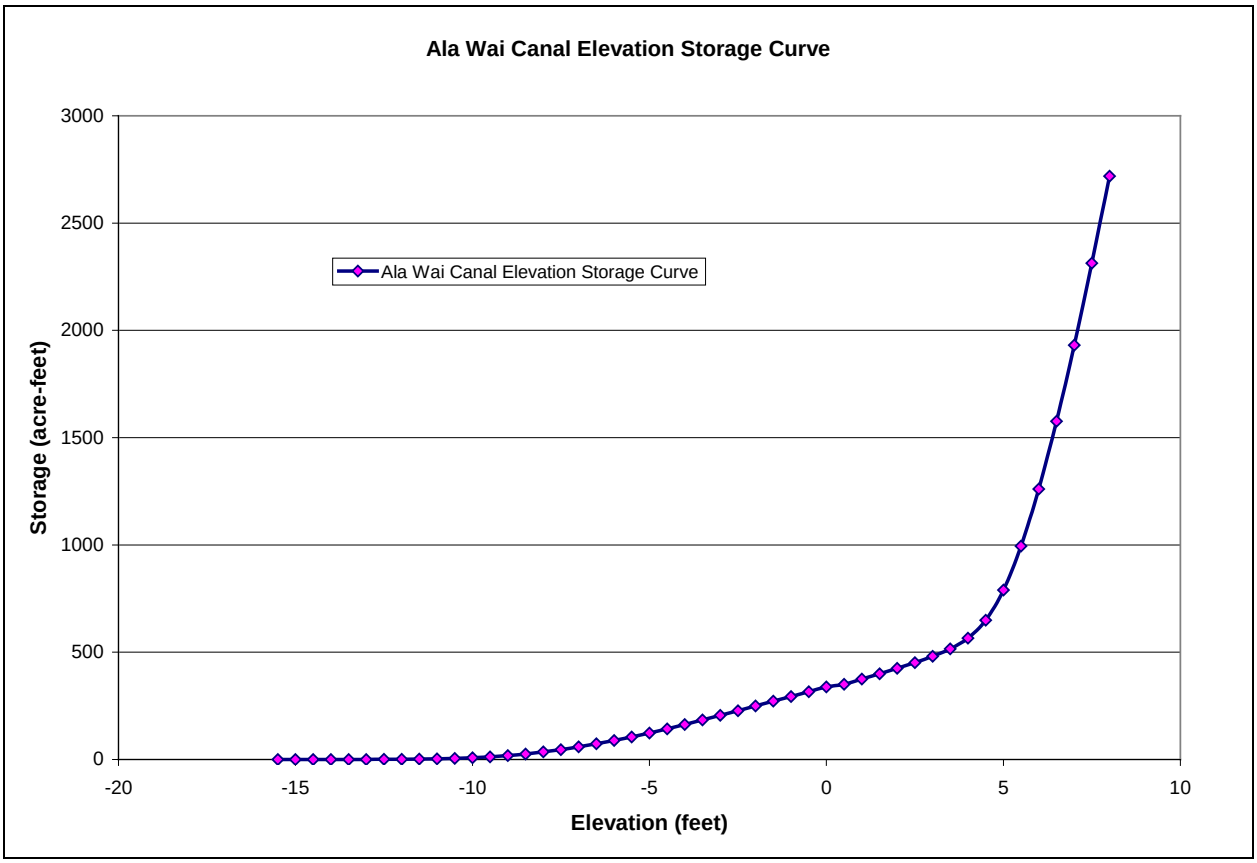

Figure 4-19. Elevation Storage Curve for Ala Wai Canal

The reservoir model was calibrated using the observed stage in the Ala Wai Canal from the October 2004 and December 1967 storm events. For modeling of the 2004 storm, the recorded stream flow hydrograph at USGS stream gage 16247100 was used to represent the inflow from upstream of Manoa and Palolo Streams; and Makiki calibrated model hydrograph at JK2 (USGS stream gage 16238000) was used to represent the inflow from Makiki area. Figure 4-20 illustrates the HEC-HMS model layout for October 30, 2004 storm calibration. Figure 4-21 shows the modeled and observed stages in Ala Wai Canal. The stage peak time matched very well at about 20:15pm with only 0.1 foot difference between the observed stage and the modeled stage.

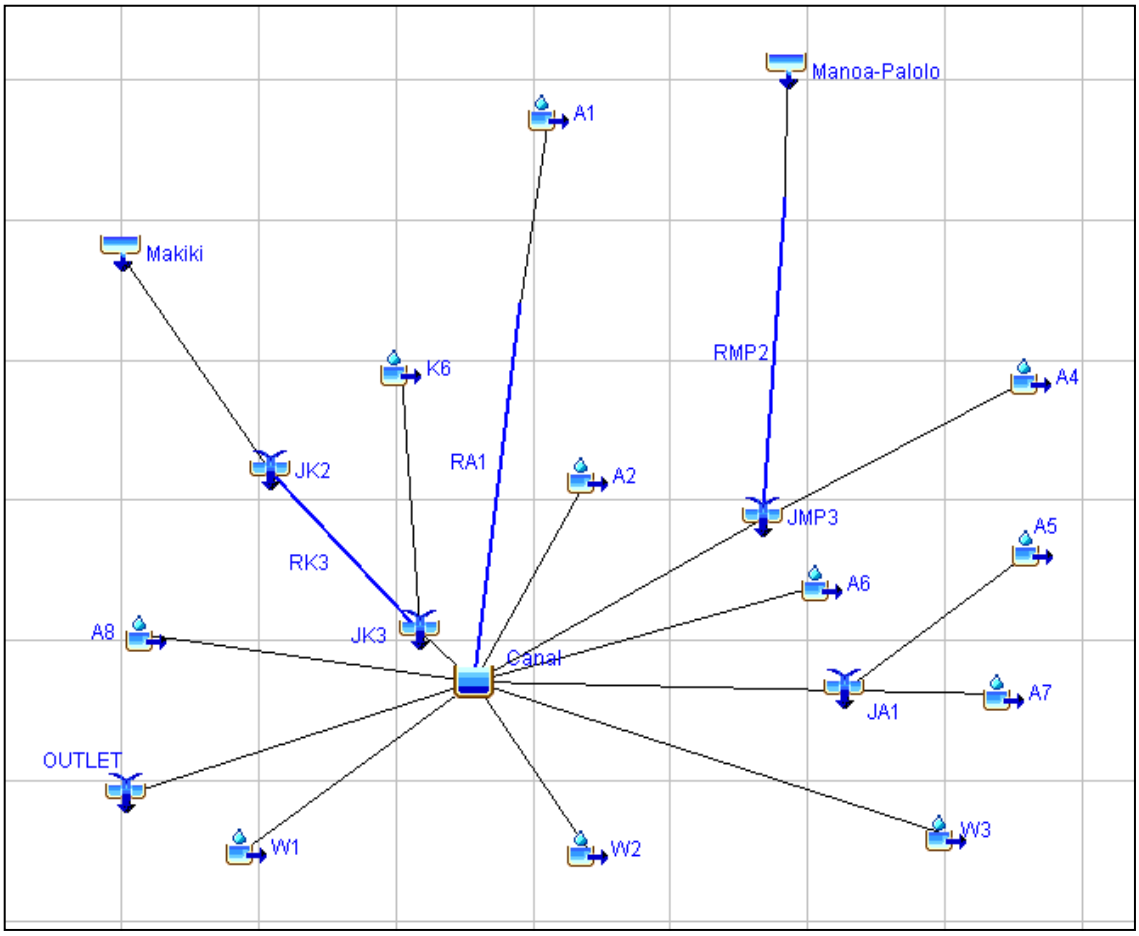

Figure 4-20. Model Layout for 2004

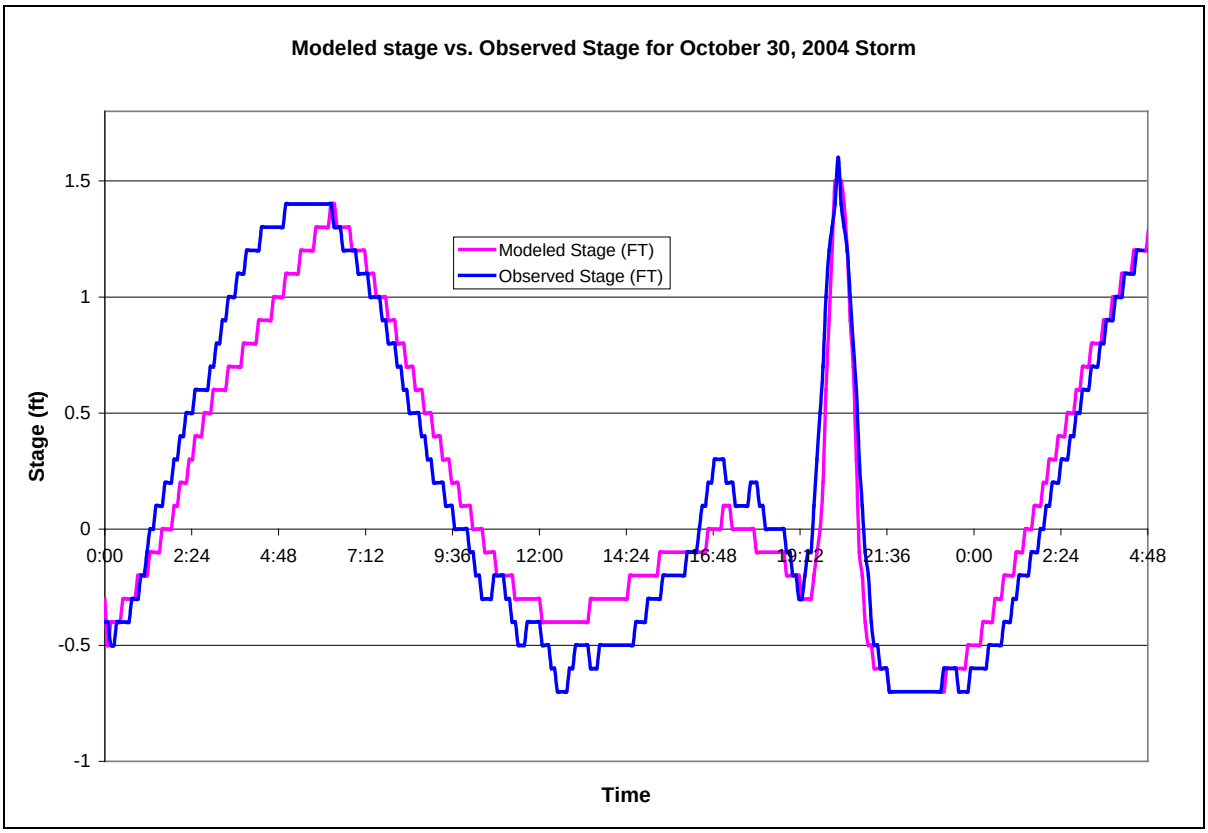

Figure 4-21. Calibrated Water Elevation vs. Observed Stage for Ala Wai Canal on October 30, 2004 Storm

For modeling of the December 17—18, 1967 storm, the calibrated Mānoa-Pālolo model hydrograph at USGS stream gage 16247100 was used to represent the upstream inflow. The finalized Makiki model described in Section 4.5 was used to represent the Makiki sub-watershed. Figure 4-22 shows the HEC-HMS model layout for calibrating this storm. The DLNR post flood report (1968) noted that Ala Wai Canal in Waikiki overflowed at the confluence with Mānoa-Pālolo Drainage Canal. Ala Wai Boulevard and adjacent streets near the confluence were flooded with water up to two feet deep (DLNR, 1968). The modeled peak stage was about 4.4 feet, or about 2.2 feet above Ala Wai Boulevard. Figure 4-23 shows the modeled stage in feet.

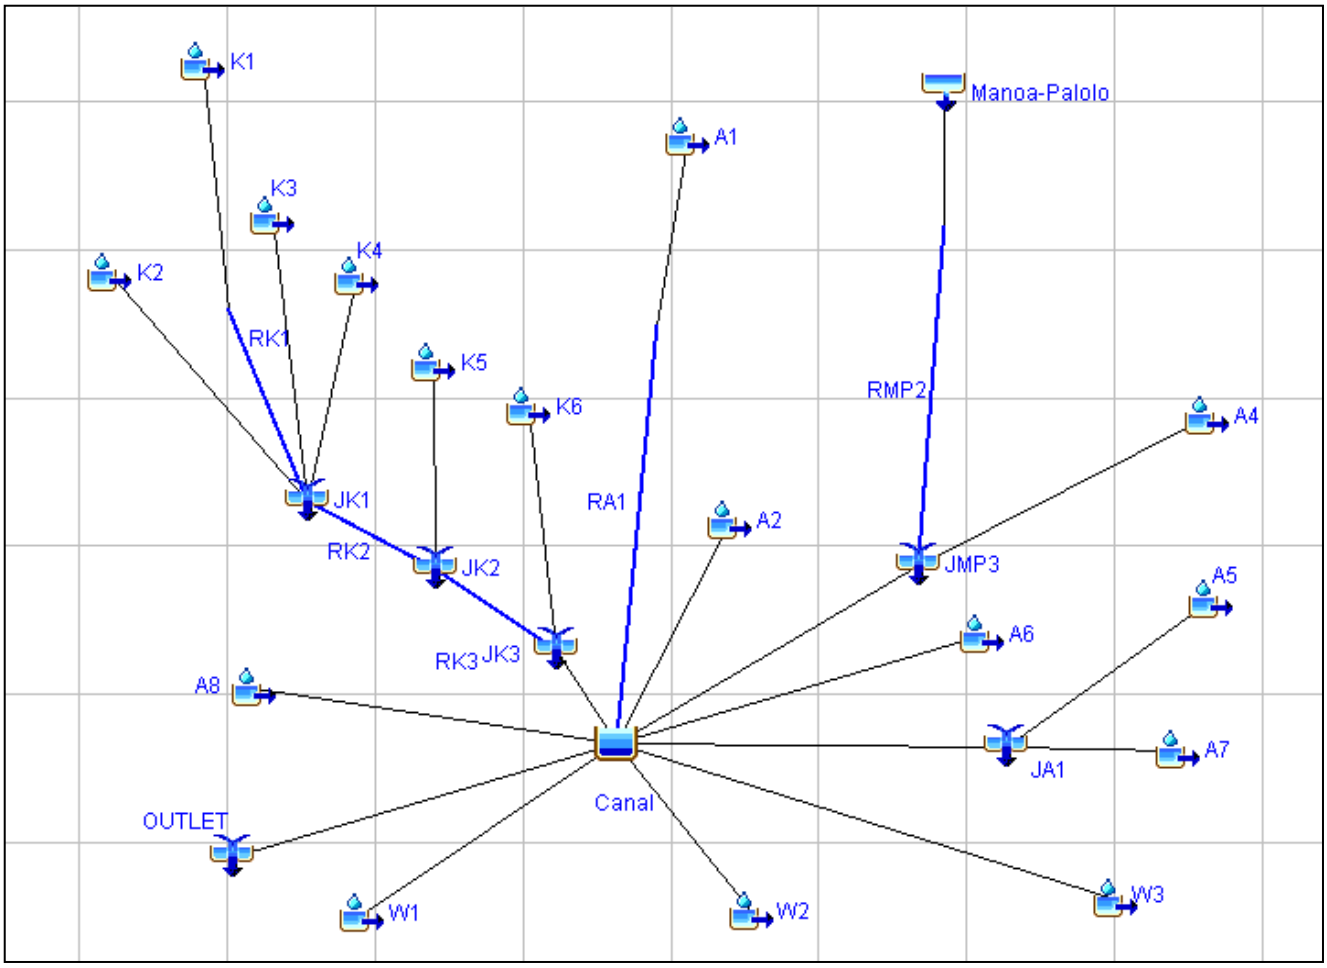

Figure 4-22. Model Layout for 1967

4.7.2 Reaches: Muskingum-Cunge and Modified Puls Channel Routing

The Muskingum-Cunge channel routing parameters were used and included the Manning's *n* values, length, slope, and cross-sections. The Manning's *n* values for the stream channel and its banks were determined using Chow's (1959) guidelines and channel conditions. The length of each reach was determined using GIS Arcview 3.3 maps; the slopes were estimated using contours generated from LiDAR data; and the widths were determined from field measurements and the cross-sectional data obtained from GeoRAS. The channel routing parameters are shown in Table 4-19.

Muskingum-Cunge Channel Routing for HEC-HMS Model

Reach	Length (ft)	Slope (ft)	Manning's n	Shape	Width (ft)	Side Slope (xH:V)
RK1	4350	0.0415	0.05	Trapezoid	10	2
RK2	2650	0.0101	0.03	Trapezoid	20	2

RP5	4300	0.0186	0.0162	Rectangle	30	----

Table 4-19. Muskingum-Cunge Channel Routing for HEC-HMS Model

The Modified Puls Routing Method was used for the Ala Wai Canal modeling to take backwater effects into consideration. The Modified Puls Routing Method is also called storage routing or level pool routing and is most often applied to reservoir routing. Because the Ala Wai Canal was modeled as a reservoir, the stream reaches that discharge into the reservoir were modeled using the Modified Puls Routing Method. The storage-discharge functions for reaches RMP2 (Mānoa-Pālolo Canal) and RK3 (Makiki Stream) were defined based on the elevation-discharge measurements of stream gages 16247100 at the Mānoa-Pālolo Canal and 16238000 at King Street bridge. The storage-discharge function for reach RA1 (Alanaio Stream) was defined by using Manning's equation. Figure 4-24 shows the locations of these three reaches. Figures 4-25, 4-26, and 4-27 Show the storage-discharge curves for these three reaches, respectively.

4.8 Inflow Hydrographs at Kānewai Gage

For consistency with the previous Mānoa Watershed Project hydrologic study, the final results from that study were used to represent the whole Mānoa sub-watershed at the Kānewai Field stream gage. Inflow hydrographs were obtained from the HEC-HMS model of the Mānoa Watershed Project study for the storm chance exceedances of 50 through 0.2 percent. Table 4-20 lists the peak discharges at the Kānewai Field stream gage (USGS 16242500). Figures 4-28 and 4-29 provide the modeled stream flow at Kānewai Field, based on the results from the Mānoa Watershed Project hydrologic study (Oceanit 2008).

Peak Discharges at Kānewai Field Stream Gage from Mānoa Watershed Project								
Return Period (yr)	**2**	**5**	**10**	**20**	**50**	**100**	**200**	**500**

4.9 Peak Flow Results

For predicting the peak discharges for various return periods, the frequency storm with an intensity position at 50 percent was used in computing the peaks and hydrographs. The HEC-HMS model predicted peak discharges at various junctions in the Ala Wai Watershed are listed in Table 4-21. The final HEC-HMS model layout is shown below in Figure 4-30.

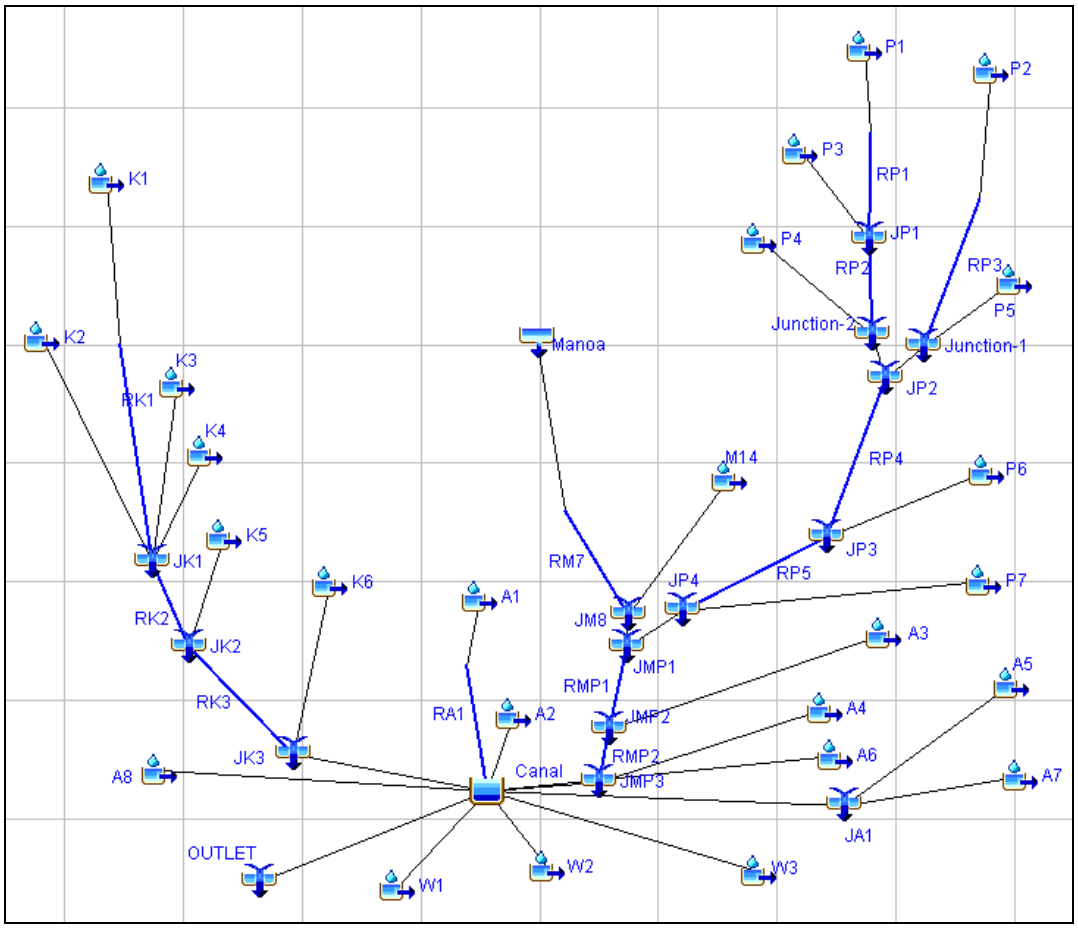

Figure 4-30. Ala Wai Watershed HEC-HMS Model

Table 4-21. HEC-HMS Model Predicted Peak Discharges at Junctions

4.10 USGS Regression Equations and City and County's Plate 6

Regional regression equations developed by the USGS (Wong, 1994) for estimating peak discharges for the 50-, 20- 10-, 4-, 2-, and 1-percent chance exceedance probabilities at gaged and ungaged sites were used to calculate peak flows in the sub-watersheds. The equations for Leeward O'ahu were used for the sub-watersheds in this study. The drainage area (DA) and median annual rainfall (P) in these equations are independent parameters. These regression equations are valid for ungaged sites when (1) the drainage areas are between 0.03 and 45.7 square miles; (2) where less than 36 percent of the area is urbanized; and (3) the median rainfall is between 29 and 239 inches. The median annual rainfall for each sub-watershed was determined from DLNR (1982). The median annual rainfall amounts for the junctions were calculated by the weighting mean method with respect to the sub-watershed areas. The equations used bias-correction factors along with the accuracy of the estimates in equivalent years of record (Wong, 1994). The peak discharges calculated using these regression equations and Plate 6 of the City's drainage standards (2000) for each junction are presented in Table 4-22. The accuracy of these results is 16 years for the 1 percent chance exceedance event and 15 years for the other storm events.

The City storm drainage standards (2000) specify the use of the rational method for drainage areas of 100 acres or less and Plate 6 for drainage areas greater than 100 acres, and this method was used for some of the sub-basins in the Ala Wai Watershed study area. Plate 6 is an envelope curve developed from maximum known peaks and regression analysis of 100-year peak flows. This curve is assumed to represent a 100-year peak flow but actually has a slightly higher return period (Wong 1994). The accuracy of this curve is based not on the average years of recorded data but by the

standard error of regression. The accuracy of data used for peak determination of the 100-year envelope is unknown. In the absence of accurate data, an equivalent years of record of 10 years is assigned (Interagency Advisory Committee on Water Data 1982).

Plate 6 was applied to calculate the 100-year peak discharges in all sub-basins because the corresponding drainage areas exceed 100 acres. Plate 6 provides three curves relating to the peak discharge of the 100-year return period storm (1 percent chance exceedance probability). Curve B from Plate 6 was used for the Mānoa sub-watershed.

Table 4-22. USGS Regression Equations and Plate 6 Calculation

4.11 FEMA Flood Insurance Study

The hydrologic and hydraulic analysis for the original Flood Insurance Study (FIS) for the City and County of Honolulu was performed by R.M. Towill Corporation in 1976. FEMA revised the previous FIS for the City and published the most updated FIS in 1979.

For Makiki Stream, USGS regression equations were used to obtain peak flow discharges for the 10-, 50-, and 100-year flooding events (FEMA, 2004). The 500-year flood was determined by a regression equation utilizing the same basic data and regression techniques as applied by USGS. These regression equations applied the ratio of the drainage area covered by forests and vegetation to total drainage area in percent instead of the median rainfall that current USGS regression equations applied to determine the peaks. Figure 18 in FIS (FEMA, 2004) was the results that only applied to one place with the drainage area as about 2.49 square miles. This drainage area is equal to the drainage area of junction JK2; in other words, only junction JK2 is available to have FEMA flood insurance analysis peak flow discharges.

For Palolo Stream, peak discharges were based on a statistical analysis results by using the 25-year recording annual peaks at USGS Gaging Station 16247000. The analysis followed the standard log-Pearson type III method procedures as outlined by the Water Resources Council. So the FEMA FIS analysis for Palolo Stream is only applied to junction JP3 that USGS gage 16247000 located.

For Manoa-Palolo and Ala Wai Canals, the peak discharges were determined by using SCS hydrograph method. Probably because of the higher proportion of urbanized areas, the SCS method resulted in slightly higher peak discharges.

For JM8, which is part of Manoa sub-watershed, same analysis was used as previous Manoa watershed study conducted by Oceanit (2008b).

Table 4-23 shows the FEMA flood insurance study analysis for Makiki, Palolo, Manoa-Palolo Canal and Ala Wai Canal.

Peak Flow Discharges in cfs Calculated by FEMA				
Return Period (yr)	10	50	100	500
Percent Chance Exceedance	10%	2%	1%	0.2%
JK2	1,850	3,250	3,950	5,950
JM8	7,600	11,500	13,600	17,000
JP3	2,790	4,510	5,340	7,530
JMP2	12,000	19,200	23,000	28,500
Ala Wai Canal	13,700	23,000	28,200	36,200

Table 4-23. Peak Flow Discharges Calculated by FEMA

4.12 Flow Frequency Analysis

HEC-SSP version 1.0 Beta was used to perform the flow frequency analysis. This software is limited to performing flood flow frequency analysis based on Bulletin 17B, "Guidelines for Determining Flood Flow Frequency" (Interagency Advisory Committee on Water Data 1982). Three USGS stream gages that have sufficient data to perform the flow frequency analysis are within the study area. The USGS stream gage 16247100 at the Mānoa-Pālolo Canal (Junction JMP2), adjacent to the Kaimukī High School, has a drainage area of 10.34 square miles. Thirty-eight effective annual peaks were used in the HEC-SSP model to predict the peaks for the various return periods at this junction. The USGS Pālolo Stream gage 16247000 (Junction JP3) has a drainage area of 3.62 square miles. Thirty-two effective annual peaks were used at this junction. The USGS Pūkele Stream (tributary of Pālolo Stream) gage 16244000 (Junction JP1) has a drainage area of 1.15 square miles. Fifty-nine effective annual peaks were used at this junction. The following figures and tables show the flow frequency results from HEC-SSP model (Figures 4-31-33 and Tables 4-24 through 4-26).

At USGS Gaging Station 16247000, there are 32 effective annual peaks available to perform the statistical frequency analysis. The continuous recorded annual peaks are from 1953 to 1979 and from 2003 to 2007, but no data is available between 1980 and 2002. The recorded annual peaks from 2003 to 2007 seem incorrect for the following two reasons.

(1) On October 30, 2004, the recorded peak at this gage was 776 cfs. The tributary stream gage upstream (Pukele) recorded a 753 cfs peak, and another tributary (Waiomao Stream) received the same rain as Pukele Stream received. At USGS gage 16247100 downstream, the recorded peak was 9,380 cfs and the Manoa Stream at Kanewai gage recorded a peak at 5,860 cfs. Thus, the peak flow at the Palolo gage should be in a range of 1,500 to 3,000 cfs rather than the 776 recorded because it received similar rainfall as Manoa.

(2) The peak for March 31, 2006 storm at Palolo Stream Gage was 1,390 cfs, at downstream gage USGS 16247100, the recorded peak was 9,320 cfs, the rainfall was uniformly distributed into the study area, the Palolo valley should have generated a range 2,000 to 3,000 cfs peak flow. Since there was possible channel conditions changed during the last 50 years, the data in this gage may be lower than actual stream flows, as a result, the HEC-SSP and FEMA analysis (used 25-year annual peaks) got lower peak discharges.

5 Results of Hydrologic Model

All of the hydrologic analysis methodologies estimate peak flow discharges (cfs) for return periods (percent chance exceedance storms) by junction; the methodologies include the HEC-HMS modeling, the USGS regression method, City Plate 6, FEMA Flood Insurance Study, and the HEC-SSP model. Each of these methodologies provides a predictive measure for peak discharges, and used together they offer a clear and accurate depiction of where peak flows will occur during 50, 20, 10, 5, 2, 1, 0.5, and 0.2 percent chance exceedance storms.

5.1 Determination of Final Peak Flow Discharges

The USACE Engineer Manual (EM) 1110 – 2 -1619 (1996, Table 4-5, page 4-5) provides guidelines to assign accuracies to flood frequency estimates determined by various methods in term of equivalent years of record. Estimates assigned higher equivalent years of record are considered more reliable than those with lower equivalent years of record. Equivalent years of record is an assigned unit of accuracy. In comparing methodologies, those with higher equivalent years of record were considered more accurate and given greater weight. Based on engineering judgment following the guidelines, the HEC-SSP model is the most reliable with equivalent years of record 59, 32, and 38 for junctions JP1, JP3, and JMP2, respectively. The HEC-HMS model was calibrated to three historical storms for Manoa and Palolo sub-watersheds, two historical storms for Ala Wai Canal reservoir model, and one historical storm event for Makiki sub-watershed. Although there was no calibration to the urbanized sub-basins, the parameters physical measurable Kinematic Wave transform method was applied. An equivalent record length of 20 years was assigned to the results generated by HEC-HMS model based on guidelines provided in EM 110-2-1619 (USACE, 1996) and the confidence in the calibration data sets.

FEMA flood insurance study within Ala Wai watershed area applied various methods to determine the peak discharges, based on the analysis done with equivalent record lengths of 15 years and were assigned to FEMA results in junctions JK2, JM8, JMP2, and Ala Wai Canal. An equivalent record length of 25 years was assigned to FEMA results in junction JP3 in response to its statistic analysis using 25-year recorded annual peaks. The weighting factors for the HEC-HMS modeling, the USGS regression, City Plate 6, FEMA Flood Insurance Study, and the HEC-SSP methodologies are shown in Table 5-1.

Weighting Factors for Peak Discharges Development								
Methodology	Accuracy in Equivalent Years of Record							
Percent Chance Exceedance	50%	20%	10%	5%	2%	1%	0.5%	0.2%
HEC-HMS	20	20	20	20	20	20	20	20
Regression	15	15	15	15	15	16		
Plate 6						10		
FEMA			15 25(JP3)		15 25(JP3)	15 25(JP3)		15 25(JP3)
HEC-SSP	59(JP1) 32 (JP3) 38(JMP2)	59(JP1) 32 (JP3) 38(JMP2)	59(JP1) 32 (JP3) 38(JMP2)	59(JP1) 32 (JP3) 38(JMP2)	59(JP1) 32 (JP3) 38(JMP2)	59(JP1) 32 (JP3) 38(JMP2)	59(JP1) 32 (JP3) 38(JMP2)	59(JP1) 32 (JP3) 38(JMP2)

Table 5-1. Weighting Factors Used To Develop Final Peak Flow Values

Determination of the final peak flow discharges at junctions of interest for the sub-watersheds studied was conducted in three steps: (1) the peak flow discharge values produced by each method were weighted; (2) all the available peak flow discharge values were plotted on log probabilistic graph paper by percent chance exceedence; and (3) the best fit curve of the peak flow discharges was graphed assuming watershed linearity, that is, that the peak flow discharge-frequency curves should be defined by a single function (illustrated as a smooth curve) for each sub-watershed. Engineering judgment was used in the selection of the best fit curve to account for the relative accuracies of each method and for the up and downstream relationships to determine the resulting final peak flow discharge values.

The determination of final peak flow discharges assumes that the sub-watersheds examined in this study exhibit linearity, meaning that a single function may describe the runoff from a sub-watershed. Sub-watershed linearity is based on the concept that peak flow discharge frequency curves serve their descriptive purpose as continuous, smooth curves. Thus, even after peak flow discharges were weighted and plotted on log-probabilistic graph paper, the best curve fit for these discharge values was determined using engineering judgment. The best fit curve was the final step in determining peak flow discharge values at the junctions of interest.

5.2 Makiki Peak Flow Discharges

Peak flow discharges at junctions of interest in the Makiki sub-watershed were weighted according to the process detailed in Section 5.1, plotted on log-probabilistic graph paper, and a best fit curve was analyzed. Table 5-2 provides peak flow discharge results for the Makiki sub-watershed at junctions of interest by methodology, the weighted values, and the 'FINAL' best fit values.

Methodology	Peak flow discharge (cfs)							
Return Period (yr)	**2**	**5**	**10**	**20**	**50**	**100**	**200**	**500**

Table 5-2. Peak Flow Discharges at Makiki Junctions by Methodology

The junction near the confluence of the Makiki Stream and Ala Wai Canal (JK3) received the highest amount of peak flow discharge in the Makiki sub-watershed. This was expected, because JK3 represents the flow exiting the entire Makiki sub-watershed. The peak discharge values attained by the Plate 6 and Regression methods appear higher than the peak discharge values attained through HEC-HMS modeling, as seen in Figures 5-1 through 5-3. As mentioned in Section 5.1, the peak discharge values were not only weighted, but also the final values were determined by the best fit curve shown in Figures 5-1 through 5-3. This best fit curve takes into account all of the methods used. In short, the final best fit curve was used to calculate the final peak discharges. Figures 5-1 through 5-3 graph the peak flow discharge by methodology over the percent chance exceedance for Makiki junctions of interest.

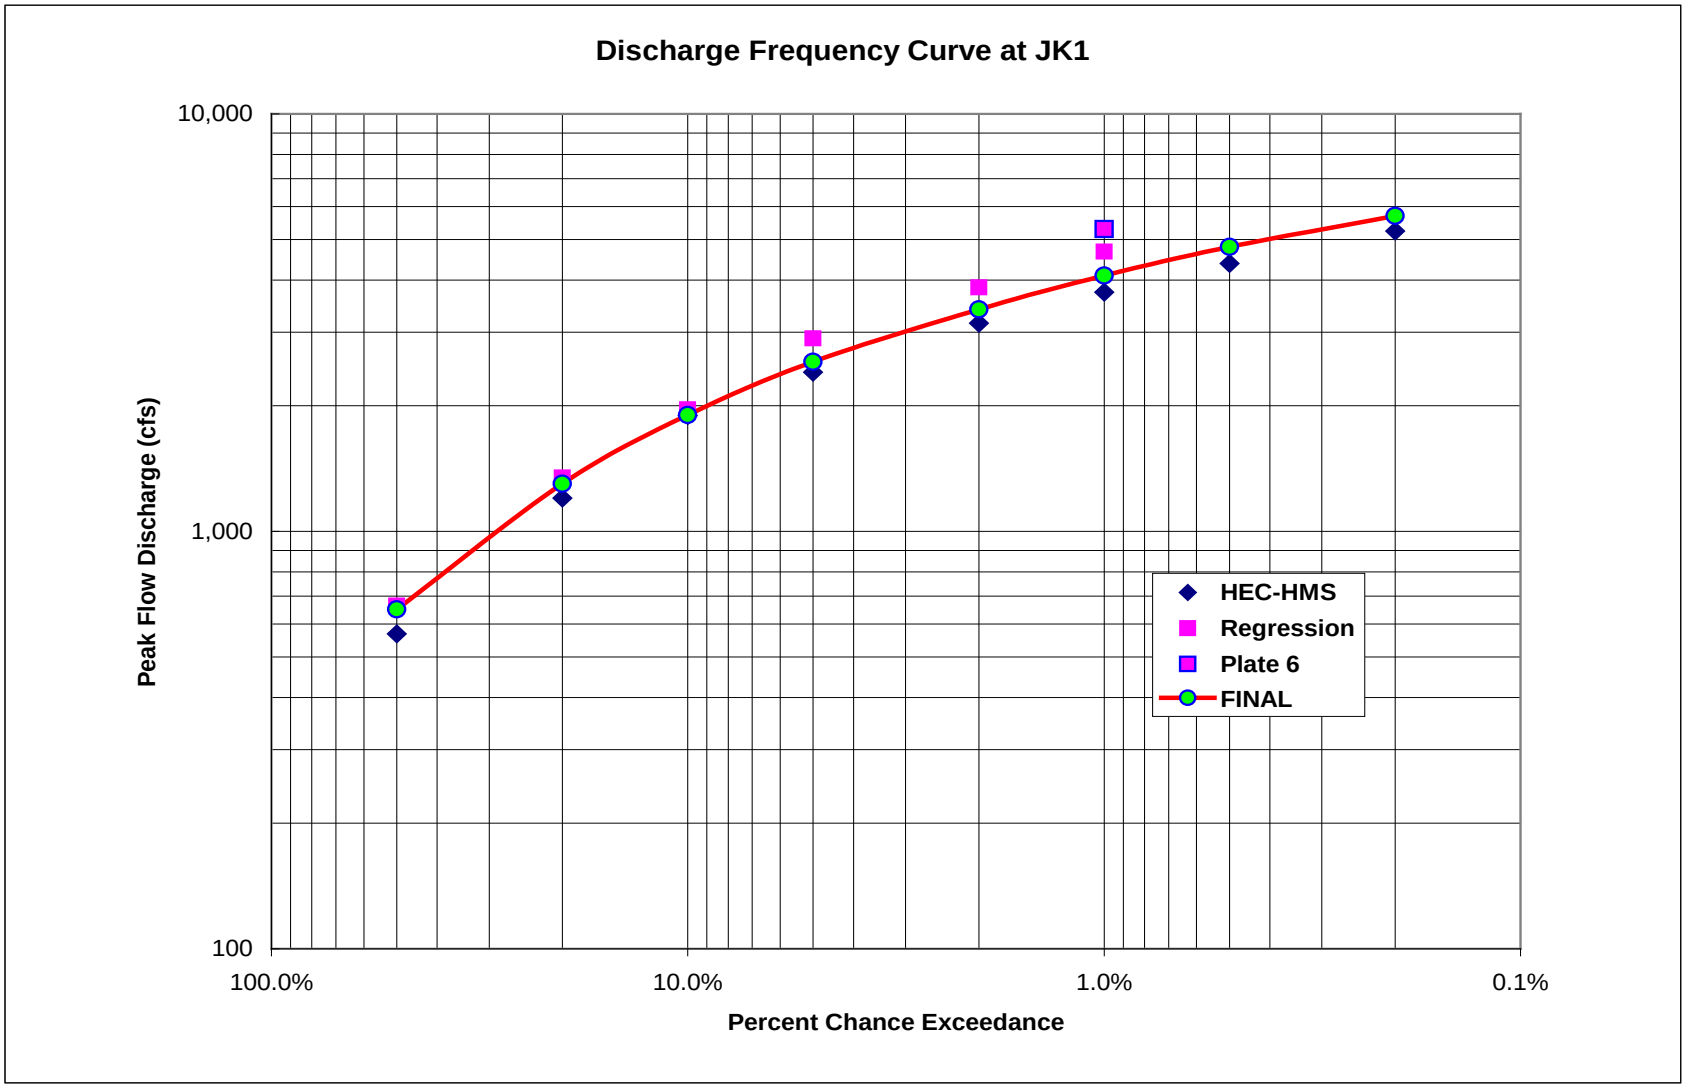

Figure 5-1. Final Discharge Frequency Curve at JK1 (Confluence of Makiki and Kanahā Streams)

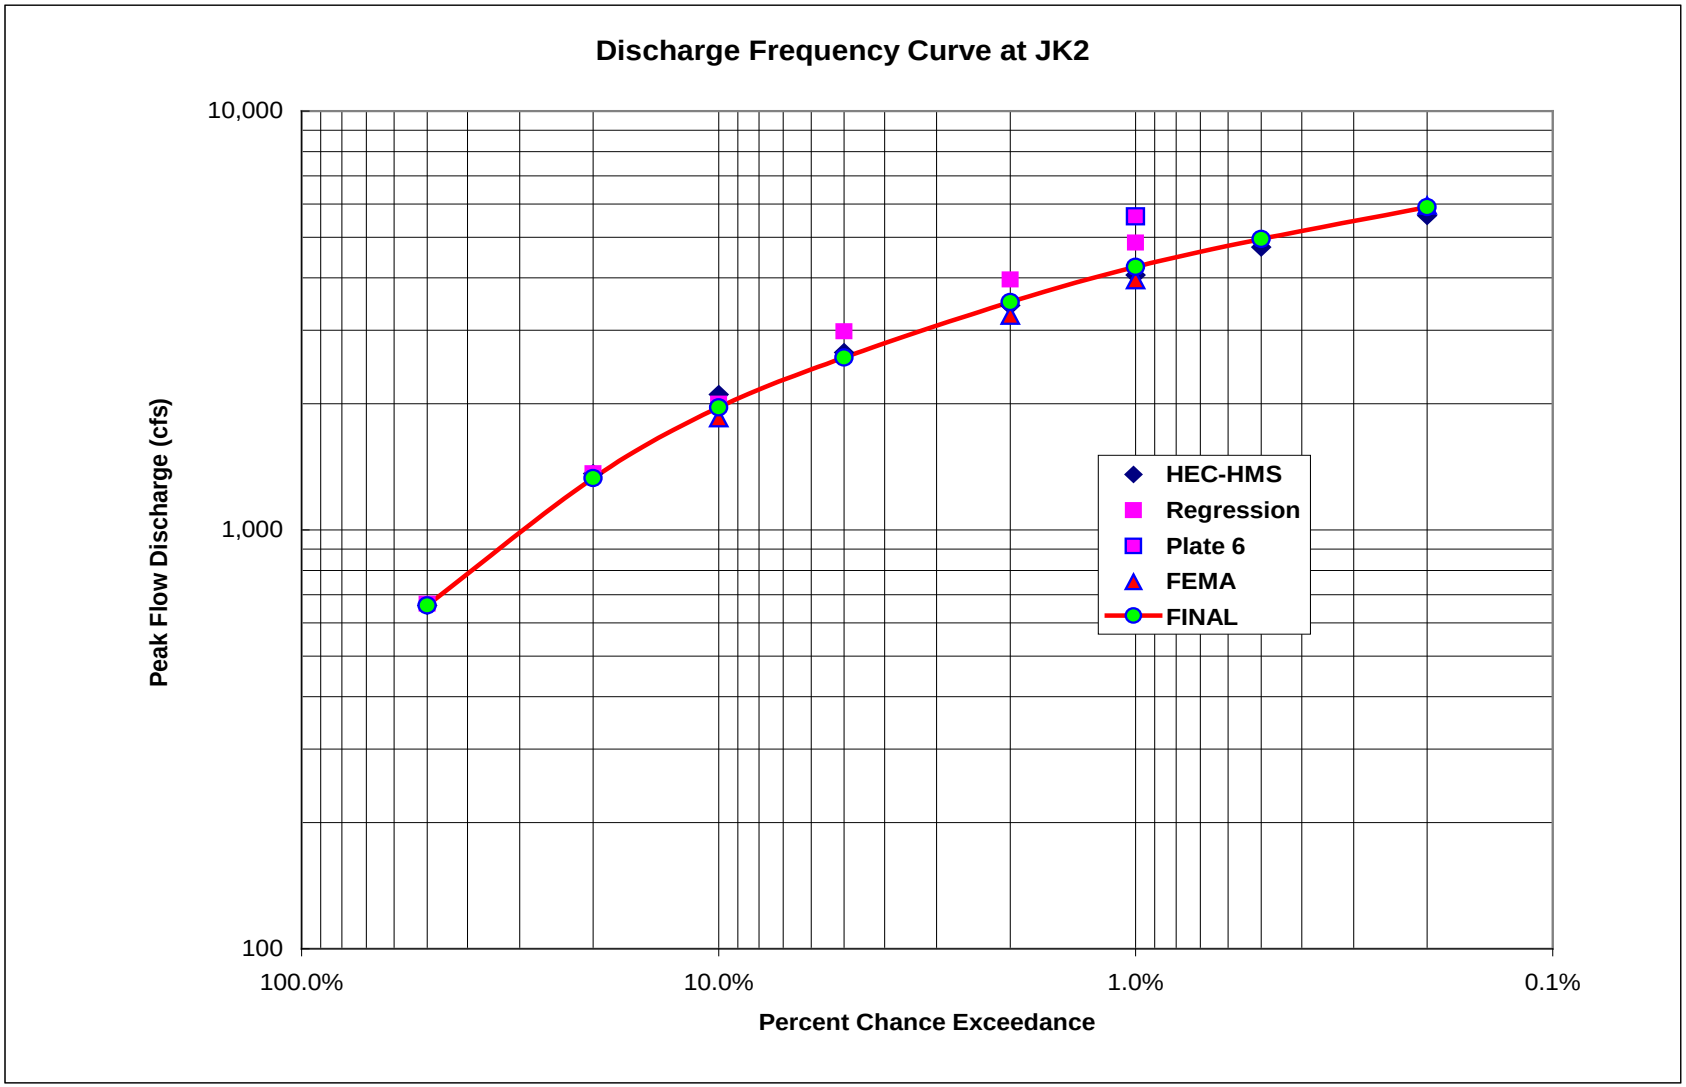

Figure 5-2. Final Discharge Frequency Curve at JK2 (USGS Stream Gage [16238000])

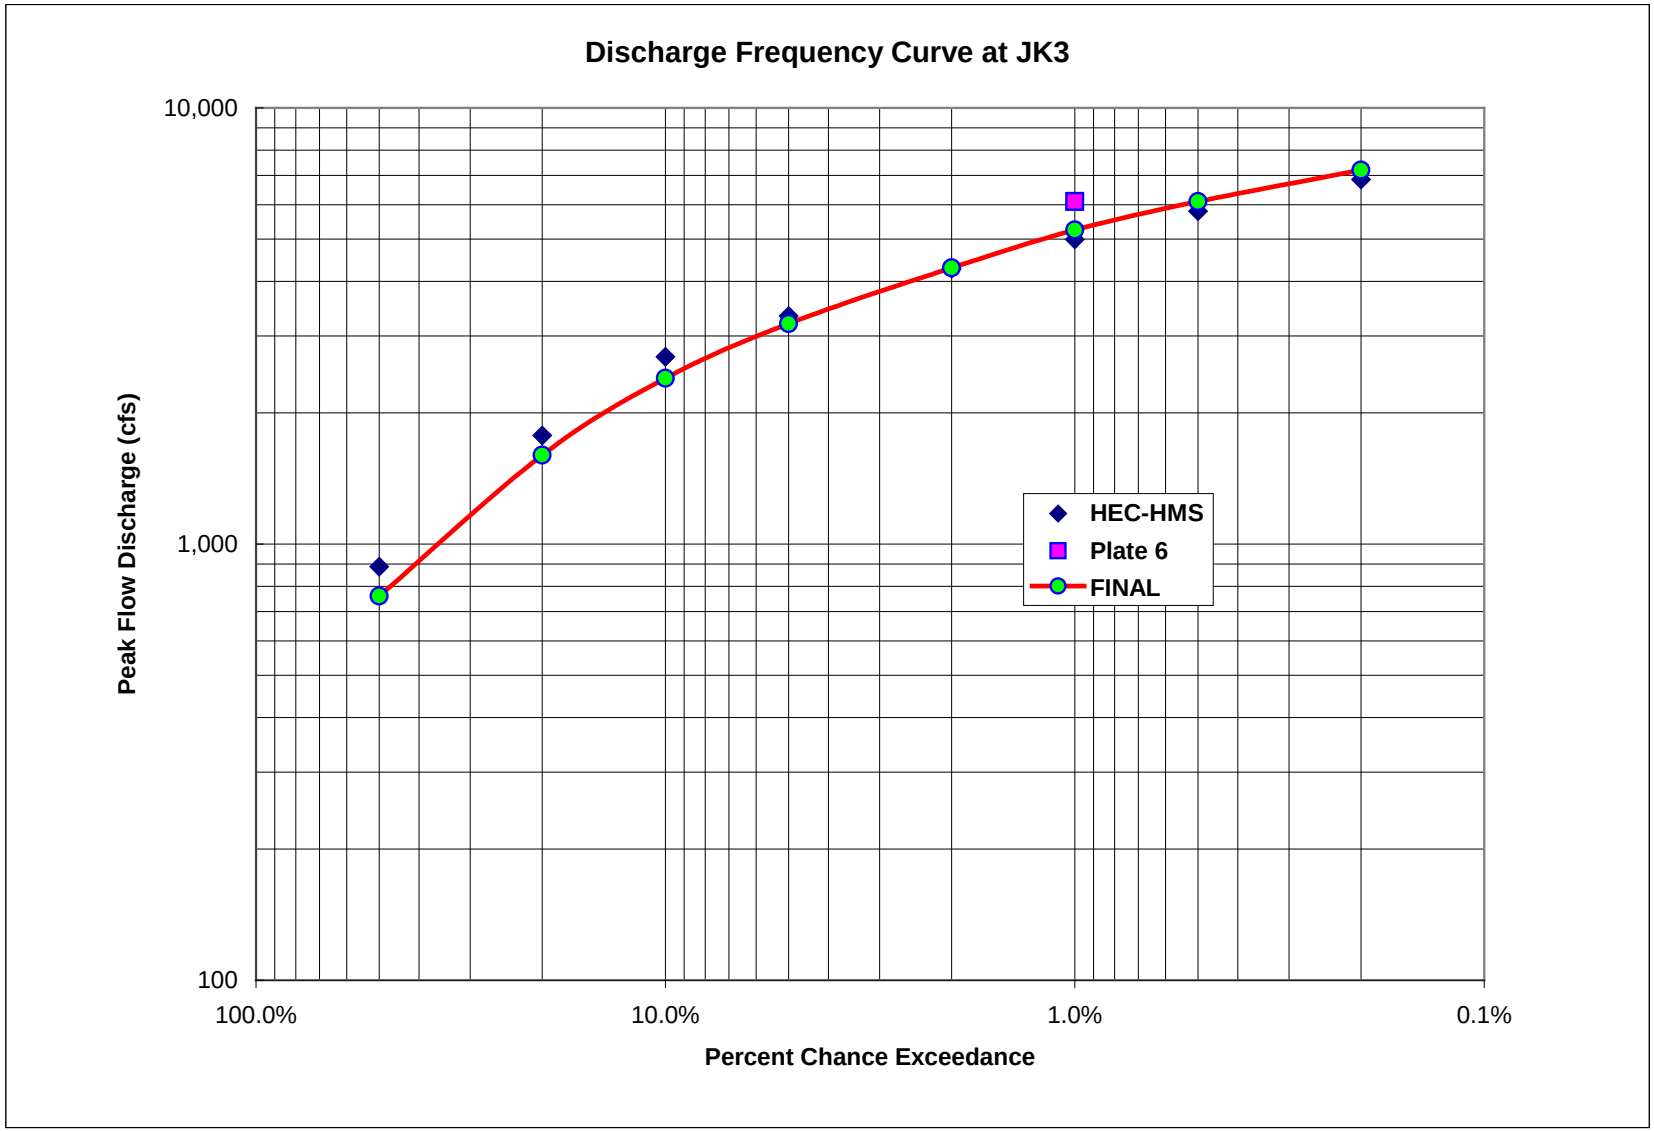

Figure 5-3. Final Discharge Frequency Curve at JK3 (Confluence of Makiki Stream and Ala Wai Canal)

5.3 Mānoa Peak Flow Discharges

Peak flow discharges for the Mānoa sub-watershed were determined in a previous study, and these values were used for the current study. The HEC-HMS peak flow discharges calculated in the Mānoa Watershed Project hydrology report (Oceanit 2008b) at the junction just upstream of the confluence of the Mānoa and Pālolo Streams (JM8) were used. This junction, JM8, is where flow exits the Mānoa sub-watershed, and thus this peak discharge value accounts for all the runoff exiting the Mānoa sub-watershed. Table 5-3 provides the peak flow discharge results by methodology and the 'FINAL' values. The final peak flow discharges from this study are plotted in Figure 5-4.

Methodology	Peak flow discharge (cfs)							
Return Period (yr)	**2**	**5**	**10**	**20**	**50**	**100**	**200**	**500**
Percent Chance Exceedance	**50%**	**20%**	**10%**	**5%**	**2%**	**1%**	**0.5%**	**0.2%**

Table 5-4. Peak Flow Discharges at Pālolo Junctions by Methodology

The junction that is just upstream the confluence of the Mānoa and Pālolo streams (JP4) receives the highest amount of peak flow discharge in the Pālolo sub-watershed, as it is situated at the downstream (*makai*) end of the watershed and drainage system. In the Pālolo sub-watershed, at the Pūkele Stream gage junction (JP1), the regression method calculates higher flow discharge values than other methods, and the HEC-HMS model seems to underestimate the peak flow discharges for many of the storms under study; the discharge frequency curve fit closely mirrors the findings of the

HEC-SSP analysis which applied 59 historical annual peaks. However, at the next junction downstream, the confluence of the Pūkele and Waiʻōmaʻo Streams (JP2), all the methodologies used provide similar peak flow discharge values. The HEC-SSP analysis was not used for this junction. The discharge frequency curve for the junction at the Pālolo Stream gage (JP3) seems to be higher than HEC-SSP findings at lower exceedance probabilities, this is probably due to the shorter historical annual peak records and the incontinuous and incorrect records. Downstream at the junction just upstream of the confluence of the Mānoa and Pālolo Stream (JP4), the frequency curve fit is close to the low regression equation values. All of these results are illustrated by junction for the Pālolo sub-watershed in Figures 5-5 through 5-8. These figures graph the peak flow discharge by method over the percent chance exceedance storm.

Table 5-5. Peak Flow Discharges at Mānoa-Pālolo Junctions by Methodology

The junction directly upstream of the confluence of the Mānoa-Pālolo and Ala Wai Canals (JMP3) receives the highest amount of peak flow discharge in the Mānoa-Pālolo Canal sub-watershed. This junction is located at the downstream (*makai*) end of the watershed and drainage system, and so it is not surprising that peak flow discharge would occur at the 'bottom' of the sub-watershed as the water flows down toward sea level. For the Mānoa-Pālolo Canal junctions studied (JMP1 and JMP3), the HEC-HMS modeling results provide higher peak flow discharges than the other methodologies used, particularly the Regression method and HEC-SSP calculation. At junction JMP2 (USGS gage 16247100), the final *best* estimates are lower than HEC-SSP findings but parallel to those values. Noda and Associates (1994) used 24 historical annual peaks to determine the peak flow discharges; their result for 100 year was at 12,429 cfs, whereas in this study, HEC-SSP provided 13,700 cfs. These results are illustrated in the final discharge frequency curves Figures 5-9 through 5-11. These figures show the peak flow discharge by method and junction, and dependent on the percent chance exceedance storm.

5.6 Ala Wai Canal Peak Flow Discharges

As mentioned earlier, Ala Wai Canal was modeled as a reservoir, considering backwater effects caused by the tides due to the sub-watershed location near mean sea level. The reservoir model treated Ala Wai Canal and the adjacent lower area as a detention basin. As the modeled flood wave passes through the reservoir, storage occurs that can greatly reduce the peak flow. The magnitude of this reduction depends on the boundary setting of the modeled reservoir. The storage-elevation function for the Ala Wai Canal reservoir model was determined using bathymetric survey data for the channel and LiDAR data for the surrounding area (Section 4.6.1). No other method accounted for analysis of the surrounding storage area; consequently, the flow peaks determined by other methods are much higher than those determined by the reservoir model. In conclusion, the HEC-HMS results that modeled Ala Wai Canal as a reservoir are considered the most accurate.

Table 5-6 provides peak flow discharge results for Ala Wai Canal sub-watersheds by methodology and then weighted followed by 'FINAL' values through the best fit curve process.

Methodology	Peak flow discharge (cfs)							
Return Period (yr)	**2**	**5**	**10**	**20**	**50**	**100**	**200**	**500**

Table 5-6. Peak Flow Discharges at the Ala Wai Canal Mouth by Methodology

The inflows to Ala Wai Canal increased, whereas the outflow did not increase significantly. For example, at the 50-year frequency storm, inflow was estimated as 24,850 cfs from HEC-HMS model, and the outflow from the Ala Wai Canal was estimated as 16,700 cfs with a peak elevation of 5.4 feet. At the 100-year frequency storm, HMS model shows that inflow was 28,200 cfs, and outflow was 17,700 cfs at a peak elevation at 5.8 feet. The canal will be overtopped at this storm condition and the water will be stored in the adjacent areas. Figure 5-12 shows the peak flow discharge over the percent chance exceedance by methodology at the mouth of the Ala Wai Canal.

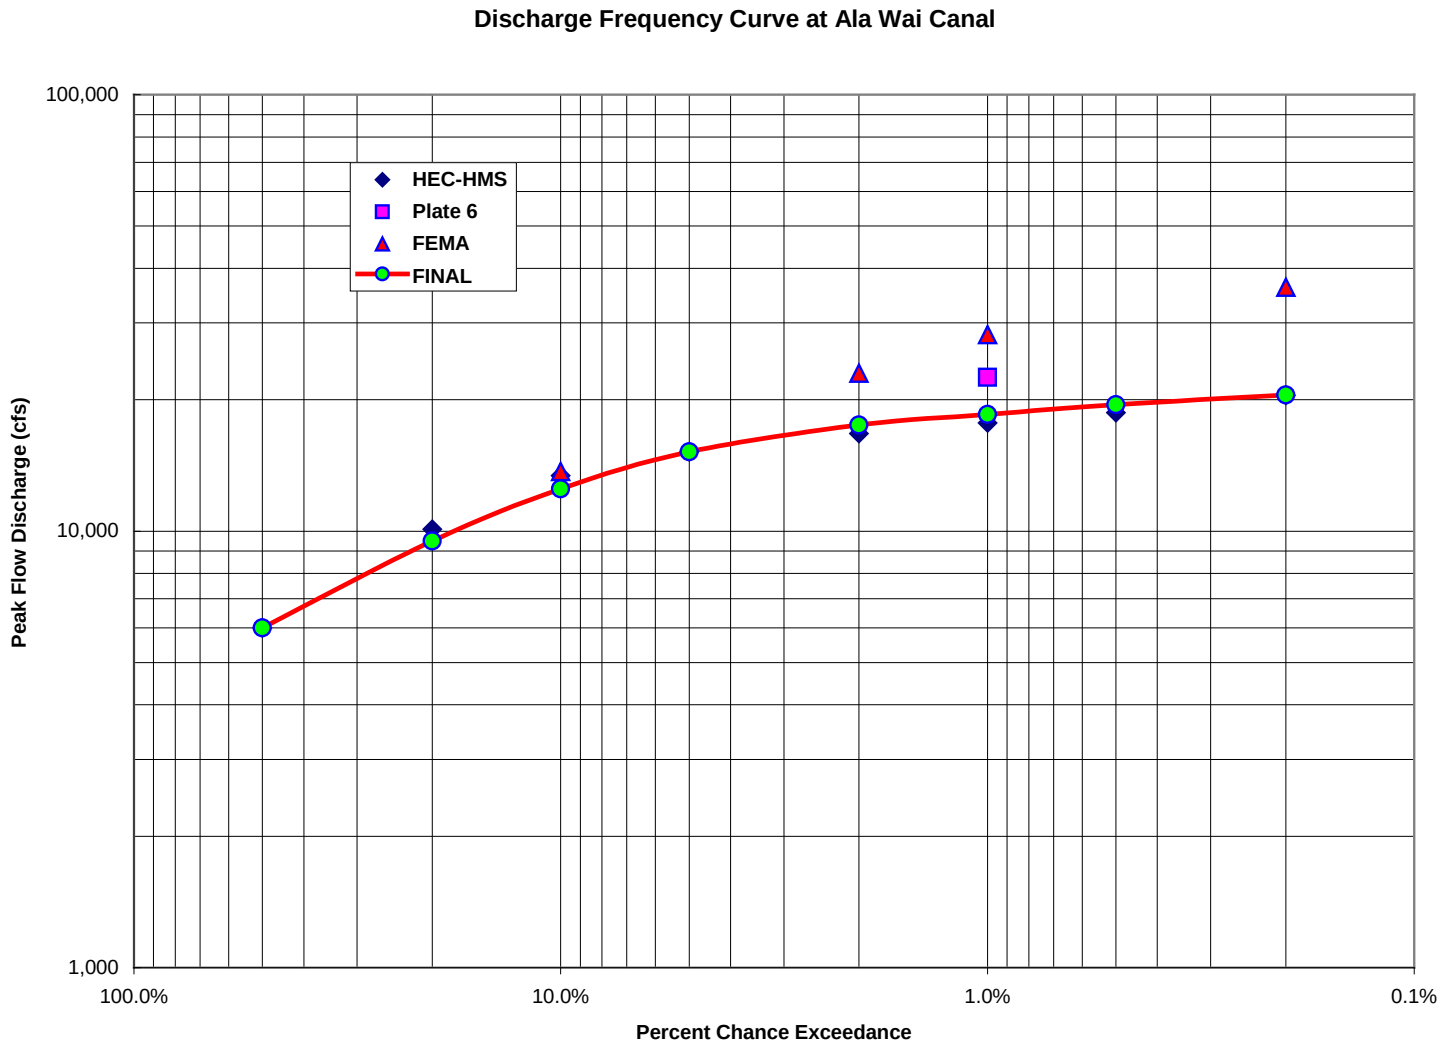

Figure 5-12. Final Discharge Frequency Curve at the Mouth of the Ala Wai Canal

5.7 Peak Flow Discharge Update (March 2016)

As discussed in Hydraulic Appendix, peak flow values were updated and adjusted based on new rainfall-frequency-intensity data and regional regression equations. When the hydrologic studies for Manoa and Ala Wai Watersheds were conducted, the 1984 rainfall frequency data for Oahu was used in the rainfall-runoff modeling (Giambelluca and others, 1984). In March 2009, the updated rainfall frequency data for the State of Hawaii was released as the Precipitation Frequency Data Server (PFDS) which is part of National Oceanic and Atmospheric Administration (NOAA) Atlas 14, Volume 4, Version 2.0, Hawaiian Islands, released March 30, 2009. Atlas 14 is official documentation of precipitation frequency estimates for the United States. Documentation can be found at: http://www.nws.noaa.gov/oh/hdsc/PF_documents/Atlas14_Volume4.pdf, last accessed September 28, 2009 while the actual; server is located at: http://hdsc.nws.noaa.gov/hdsc/pfds/hi/hi_pfds.html. This tool computes the rainfall frequency and intensity with 90 percent confidence limits for the 1- to 100-year storms for durations from 5 minutes to 60 days. The updated rainfall frequency values are presented in Table 5-7. A comparison between the previous (Table 4-1) and newer NOAA rainfall frequency duration values, indicated that the newer intensity values were higher than the older data by an average of 4 to 13 percent depending on the rainfall recurrence interval and duration. Only the lower rainfall intensity durations at the 50- and 10-percent chance storms showed the Report R-73 values to be consistently higher. In general the 10- and 1-percent (10- and 100-year) rainfall intensities, all durations (5 minutes to 24-hours) were on average higher by 0.04 inches and 0.44 inches. The NOAA values also tended to be higher in general compared to the Report R-73 for the Manoa watershed as well. Manoa watershed values were higher on average by 0.10 inches and 0.62 inches for the 10- and 1-percent chance storms. In general, the shorter frequency time periods had a larger change then the longer rainfall time periods.

The NOAA rainfall frequency duration values were used in the same HEC-HMS model as the Report R-73 rainfall frequency duration values to generate updated peak flow discharges for all frequency storm events. The average percent difference between the newer HEC-HMS peak flow values compared with the older (2008) range varied from minus 7 percent for the Manoa Stream 10-percent chance flood to plus 36 percent for the non-Manoa Stream 50-percent chance floods. In general, the Manoa watershed peak flow values did not show significant changes as the Report R-73 rainfall frequency duration values tended to be higher than the NOAA rainfall frequency duration values for the 20 to 2 percent annual chance exceedence flood events. For the non-Manoa watersheds, the NOAA rainfall frequency duration values generated peak flow values from 7 to 36 percent larger than the Report R-73 rainfall frequency duration values depending on recurrence interval. Results of the updated HEC-HMS model with the prior peak flow computations by junction are presented in Table 5-8. Table 5-8 presents all the prior data in Table 28 from the Manoa Watershed Report (Oceanit, 2008b) and Tables 5-2, 5-3, 5-4, 5-5, and 5-6 of this report. Two methods used in the Manoa Watershed study (Oceanit, 2008b) but not used in this study for the Ala Wai Watershed were the TR-55 method and FLO-2D model.

Also after the hydrologic studies for the Manoa and Ala Wai watersheds were completed, the USGS released newer regional regression equations for the State of Hawaii in 2010 (Oki and others, 2010). The newer regional regression equations for Leeward O'ahu, used the same independent variables, drainage area and mean annual precipitation, as the older 1994 Leeward O'ahu equations (Table 4-

22). Changes were in the independent variable coefficients (Oki and others, 2010, Table 13). The standard error of prediction in percent and coefficient of determination, R^2, were similar among the two sets of equations. The 1994 equations had an average standard error of prediction of 40-percent and R^2 of 0.72. The 2010 equations had an average standard error of predication of 42-percent and an R^2 of 0.75. The 2010 equations, as presented in table 5-9, provided an equation for the 0.2-percent chance flood which the 1994 equations did not. The same independent variables used with the 1994 equators were used in the 2010 equations and these results by junction are presented in Table 5-8. Note that at junctions JK3 and JMP3, the 2008 analysis did not compute regression equation results so these were added to the update in Table 5-8. Also note that the regional regression equations are provided for the 4-percent chance (25-year) flood but presented here in the various tables as the 5-perecnt chance (20-year) flood. For use of these regression equations, the two recurrence intervals were considered sufficiently close for comparison purposes in this report. Peak flow discharge values from using the 2010 regression equations resulted in values all lower than values derived from the 1994 regression equations.

Percent Chance Exceedance	Return Period (years)	Depth (inches) for Specified Duration								
		5-min	15-min	30-min	1-hour	2-hours	3-hours	6-hours	12-hours	24-hours
99	1	0.38	0.66	0.97	1.40	1.87	2.12	2.74	3.35	3.92

0.2	500	1.53	2.62	3.88	5.61	7.57	8.82	11.42	14.23	18.18

Rainfall Intensity Frequency data determined from NOAA Atlas 14 Precipitation Frequency Data Server using watershed centroid of 21.3092 N, 157.8071 W. Values for the 5-percent chance storm are interpolated.

Revision of data in Table 4-1

Table 5-7. Updated Rainfall Intensity Frequency Data for the Ala Wai Watershed, Oahu, Hawaii

As part of the update, the same weighting equations and factors (Table 5-1) were used with both the HEC-HMS computations with the NOAA rainfall frequency duration values and the USGS 2010 equation values along with prior Plate 6, FEMA, and HEC-SSP results were applicable, to provided new weighted results (Table 5-8). These newer results along with the prior computed peak flow estimates were used to determine new peak flow estimates. In many cases, for Manoa and Palolo Streams, only the rarer 0.5-percent and 0.2-perecent chance flood were revised by increasing the peak flow values. In other cases at Makiki Stream and the Ala Wai Canal, all flood frequency events were increased from the prior 2008 computed values (Table 5-8).

The updated adjusted peak discharge values by junction are listed in Table 5-8 with all computed values and more succinctly with just the final determined values in Table 5-10. As discussed prior in Section 5.1, the final determination of the peak flow discharges was based upon engineering judgment incorporating both the weighted equation values and the graphical adjustments. These values were then adjusted by location, as described in the Hydraulic Appendix for use in the HEC-RAS model. The uncertainty of the peak flow discharge values, as discussed in Section 5.1, is based on the equivalent years of record. The final equivalent years of record (EYOR) used in the risk and uncertainty HEC-FDA model is based on stream reach and is presented in Table 5-11. The Makiki Watershed with the least amount of available data was given the lowest EYOR of 18 years, while the remaining sub-watersheds were assigned values from 25 to 30 years. The highest values were from sub-basins where the peak flow discharges were almost entirely based on gaged data; Pukele and Waiomao Streams. The assigned EYOR is based on the overall confidence in the reliability or accuracy of the peak flow discharge estimates and as applied in HEC-FDA constrains the confidence limits of the sampling of peak flow discharge estimates. The HEC-FDA analytical frequency curve data is initial values and may be changed as part of the hydraulic and economic modeling efforts as described in the hydraulic and economic appendices. The analytical curve frequency values in Table 5-11 were determined from the final output discharges computed by HEC-RAS for the intermediate sea-level rise scenario (Appendix A2 and Appendix A3) and methodology in Bulletin 17B, Appendix 5 (Interagency Advisory Committee on Water Data, 1982) to match HEC-RAS input data into HEC-FDA. Actual use of analytical frequency curve values versus graphical curve values is discussed in the Economic Appendix.

1 INTRODUCTION

Through a cooperative effort undertaken by the State of Hawaii Department of Land and Natural Resources (DLNR) Engineering Division and the U.S. Army Corps of Engineers (USACE) as part of the Ala Wai Canal Project Feasibility Study, a hydrologic and hydraulic study of the Ala Wai Canal Watershed was initiated in 2001 and was amended in 2006. A large portion of this watershed is highly susceptible to flooding. The purpose of this study is to determine the feasibility of flood damage reduction alternatives for the Ala Wai Canal Watershed. This report presents a description of the analytical approach, analyses performed, and the results obtained for a detailed without-project hydraulic study and a with-project hydrologic and hydraulic study of the approximately 19 square miles of the Ala Wai Canal Watershed. Results of this study include water surface profiles for the 50%, 20%, 10%, 5%, 2%, 1%, 0.5%, and 0.2% Annual Chance Exceedance (ACE) storm events for the existing without-project conditions, future without-project conditions, and for several respective with-project alternatives.

2 GENERAL

2.1 Scope of Work

An analysis of the watershed and stream hydrology and hydraulics was performed using the U.S. Army Corps of Engineers' (HEC-HMS) Hydrologic Engineering Center's-Hydrologic Modeling System in conjunction with the (HEC-RAS) Hydrologic Engineering Center's-River Analysis System. The results of this modeling effort were used to develop depth-duration-frequency rating curves for each portion of the study. The watershed was first analyzed under current development conditions assuming no implementation of any flood damage reduction alternatives. These scenarios were then modified to include an initial array of five project alternatives aimed at reducing flood damages at different areas in the watershed. Three alternatives are described in this Appendix, Alternatives 1A, 2A, and 3A. 10% level of designs were created for Alternatives 2A and 3A.

The study area extends from the ridge of the Ko'olau Mountains to the nearshore waters of Mamala Bay and includes Makiki, Manoa, and Palolo streams. These streams all drain to the Ala Wai Canal, a 2-mile-long, man-made waterway constructed during the 1920s to drain extensive coastal wetlands, thus allowing development of the Waikiki district.

2.2 Previous Hydrologic and Hydraulic Models and Studies

Varieties of studies have been previously conducted in the Ala Wai Canal Watershed and were reviewed as part of this project. These studies include the following:

- **Federal Emergency Management Agency's National Flood Insurance Program Study (*FEMA, 1979*).** The Federal Emergency Management Agency (FEMA) contracted the U.S. Army Corps of Engineers to determine flood hazards for the McCully and Moiliili areas that encompass the Ala Wai Canal and the

Manoa-Palolo Drainage Canal. This study delineated the 1-percent ACE (100-year) floodplains and was completed in February 1979. The discharge of 28,300 cfs (cubic feet per second) at the canal mouth was used to delineate the 1-percent ACE floodplains.

- **Ala Wai Canal Improvement Project, Storm Water Capacity Study (*Edward K. Noda and Associates, 1994).*** The State of Hawaii contracted Edward K. Noda and Associates to conduct this study to determine the hydraulic effects associated with dredging the Ala Wai Canal. This study concluded that by lowering the canal invert elevation to -12.0 and -10.0 feet mean lower low water at strategic locations, the maximum 1-percent ACE (100-year) flood elevation would be at approximately 5.0 feet mean sea level near the top of the ocean side canal bank. The 1-percent ACE flow used in this study was 22,389 cfs at the mouth of the canal.
- **Ala Wai Flood Study (*USACE, 2001*).** Conducted under the Planning Assistance to States Program (Section 22, WRDA of 1974), this study investigated and recommended appropriate solutions to resolve flooding from the Ala Wai Canal. The Land Division of DLNR was the non-Federal sponsor of the study. The analysis demonstrated that there are possible structural measures that could be implemented to mitigate flooding by increasing the flood carrying capacity of the Canal. Specific measures included dredging, levees and floodwalls, and detention/sedimentation basins. The study indicated that dredging would increase the flood capacity of the channel, but would not provide full protection against a 1-percent ACE (100-year) flood.
- **Ala Wai Watershed Analysis (*Townscape Inc. and Dashiell, 2003*).** The purpose of this effort was to review existing literature and evaluate existing data to identify the water resource problems, studies, and recommended actions to improve watershed health, as related to water supply, flood control, and ecosystem restoration. This document was prepared as a component of the USACE/DLNR Ala Wai Watershed Feasibility Study.
- **Hydrology and Hydraulics Study, Flood of October 30, 2004, Mānoa Stream (*USACE, 2006*).** A storm on October 30, 2004, caused significant flooding in Mānoa Valley, especially in areas adjacent to Mānoa District Park and Woodlawn Drive Bridge. A post-flood analysis was conducted using rainfall-runoff and the 1977 stream hydraulic computer modeling (older HEC-2 model), the results of which were used to assess the feasibility of several short-term flood mitigation measures. Alternatives analyzed included construction of levees or floodwalls along sections of the channel between Mānoa District Park and Woodlawn Drive and installation of an artificial channel between East Mānoa Road and Woodlawn Drive. Of these alternatives, the channel drop structure at Woodlawn Drive Bridge was determined to have the best potential for increasing the capacity with the least amount of maintenance, aesthetic, bridge structure, and drainage impacts to mitigate. DLNR was the non-Federal sponsor of the study.
- **Final Hydrology Report, Manoa Watershed Project (*Oceanit, 2008a*).** The Natural Resources Conservation Service (NRCS) contracted Oceanit through the USACE to develop conceptual designs and prepare a feasibility report, watershed plan, and a preliminary draft environmental impact statement

(PDEIS) for alternate flood hazard reduction schemes aimed at preventing similar flooding in the future. Several rainfall runoff models and frequency-based methods were used to estimate the peak discharges at various junctions in the watershed. Rainfall runoff models included Technical Release 55 (TR-55) from the NRCS, Hydrologic Engineering Center-Hydrologic Modeling System (HEC-HMS) from the USACE, and FLO-2D, a distributed model. Frequency-based methods included the Plate 6 of the City and County of Honolulu drainage standards, USGS regression equations, and FEMA peak discharge-frequency drainage area curves. Peak discharges calculated using the above methods were compared, and best estimates of the peak discharges for the following return periods were determined: 50-, 20-, 10-, 5-, 2-, 1-, 0.5-, and 0.2-percent ACE.

- **Final Hydraulic Analysis Report, Manoa Watershed Project (*Oceanit, 2008b*).** The NRCS contracted Oceanit through the USACE to explore alternatives for flood reduction along the Manoa Stream corridor. In order to qualify the effects of each proposed alternative, the existing extent of flood inundation must be known. The Hydrologic Engineering Center-River Analysis System (HEC-RAS) was used to analyze the extent of the inundated areas from Manoa Stream for these eight storm events: 50-, 20-, 10-, 5-, 2-, 1-, 0.5-, and 0.2-percent ACE (2-, 5-, 10-, 20-, 50-, 100-, 200-, and 500-year). The 50-, 5-, 1-, and 0.2-percent ACE storms were mapped. Peak flow data at critical junctions along the stream were supplied by the Final Hydrology Report, Manoa Watershed Project (*Oceanit, 2008a*). The hydraulic analysis was conducted without debris blockages at bridge openings.
- **Technical Summary Report, Mānoa Watershed Project (*Oceanit, 2008c*).** Following the October 30, 2004, flooding event in Mānoa Valley new LiDAR data was obtained. NRCS initiated the Mānoa Watershed Project, which included development of hydrologic and hydraulic models using HEC-HMS and HEC-RAS, and design of conceptual flood reduction measures, based on the work completed as part of the Mānoa Stream Hydrology and Hydraulics Study (*USACE, 2006*). The intent of the project was to prepare a Watershed Plan and EIS under the NRCS Watershed Program (PL83-566). However, the funds needed to complete the EIS were not received, and thus the scope of the project was reduced to technical reports and conceptual measures to mitigate flooding. The results of this effort were eventually incorporated, with expansion of the hydrology and hydraulics modeling, into the Ala Wai Watershed Project.
- **Final Hydrology Report, Ala Wai Watershed Project (*Oceanit, 2008d).*** This study estimated peak flow discharges at particular drainage junctions in the Ala Wai Watershed corresponding to the following storm return periods: 50-, 20-, 10-, 5-, 2-, 1-, 0.5-, and 0.2-percent ACE (2-, 5-, 10-, 20-, 50-, 100-, 200-, and 500-year). Updates were done in November 2010 and March 2016 (Appendix A1).
- **Final Drainage Evaluation Report, Ala Wai Canal Watershed Project (*Oceanit, 2008e*).** This study evaluates the existing Ala Wai Watershed drainage facilities to determine the existing capacity of the drainage system. The existing discharge capacity is compared with the 2000 City and County of Honolulu's

Storm Drainage Standards to determine whether or not each drainage facility (mostly culverts can pass a 10-, 50-, or 100-year storm, depending on the drainage area serviced by the outlet.

- **Conceptual Engineering Report, Ala Wai Canal Flushing System & Ala Wai Golf Course Detention System (*Mitsunaga & Associates, Inc., 2014*).** The Department of Land and Natural Resources of the State of Hawaii proposes to improve the water quality of the Ala Wai Canal to standards acceptable for water recreational activities including canoeing, kayaking, fishing and minimal power boating. The specific objectives of the proposed project are to: decrease sources of pollution through detention ponds and/or filters on tributaries to the canal and improve watershed management, increase water flow and circulation in the canal while addressing environmental concerns, and define and implement maintenance management practices for the canal. This Conceptual Engineering Report developed alternatives to address the diversion of the off-site storm water through Ala Wai Golf Course and a flushing system or the Ala Wai Canal.

3 WITHOUT PROJECT HYDRAULIC MODELING

3.1 Overview

The HEC-RAS (Hydrologic Engineering Center - River Analysis System) computer program, version 4.1.0 was used for hydraulic modeling (*U.S. Army Corps of Engineers, 2010*). This HEC-RAS model was created by joining separate HEC-RAS models of Makiki, Manoa, and Palolo Streams and Manoa-Palolo Drainage and Ala Wai Canals together. The HEC-RAS model of Manoa Stream is documented in Oceanit (*2008b*) and the separate models for the Makiki and Palolo Streams and the Manoa-Palolo Drainage and Ala Wai Canals were originally created by Oceanit and West Consultants by July 2009 and then corrected and merged together by the U.S. Army Corps of Engineers by November 2009. In 2013 the merged model was then updated again to be more accurate. This model consisted of 8 rivers, 13 reaches, 1,287 cross sections, of which 476 are interpolated, 49 bridges (this includes culverts), 2 inline weirs, and 16 lateral weirs. The model was developed using data that was considered the best available at the time.

3.1.1 Study Reach Descriptions

The Makiki Stream portion of the HEC-RAS model starts from the confluence with the Ala Wai Canal to a point approximately 2.0 miles upstream and includes the Kanaha Ditch Tributary from its confluence with Makiki Stream to a point approximately 0.8 miles upstream. Due to the dominate effect of the Ala Wai Canal during high flows, the downstream reach of Makiki Stream downstream of Fern Street was not modeled in detail; both the Kapiolani Boulevard and pedestrian walkway bridges were ignored in the model. The stream channels of both Makiki and Kanaha Streams have been highly modified with concrete and confined from the point when they enter the urbanized area and include sections when the stream channel is confined to sections entirely underground.

The Manoa HEC-RAS model was modified from the Oceanit (*2008b*) by adding the potential for split flow to leave Manoa Stream near Woodlawn Drive Bridge and enter the University of Hawaii at Manoa Campus. Also the Dole Street Bridge was added to the model for completeness, although its effect on flow is very minimal as the low chord of the bridge is still about 10 ft higher than the 0.2-percent ACE flood water-surface elevation. The Manoa Stream reach extends from the confluence with Manoa-Palolo Drainage Canal upstream about 3.1 miles to the point where the Waihi and Waiakeakua Stream tributaries meet. The Manoa Stream channel is mostly natural with some segments modified by concrete channel or stream bank hardening.

The Palolo Stream Main reach extends upstream approximately 1.9 miles from the confluence with the Manoa-Palolo Drainage Canal. Upstream of Palolo Stream, the Pukele Stream and Waiomao Stream tributaries were modeled, extending 1.1 and 0.9 miles upstream. The Palolo Stream Main reach Channel is mostly confined to one large concrete channel.

The Manoa-Palolo Drainage Canal is called the Palolo Stream Lower reach in the model and extends about 0.9 miles from the Ala Wai Canal to the confluence of the Manoa and Palolo Stream. This canal consists of a modified channel with segments of natural bed and banks, but mostly hardened stream banks.

The Ala Wai Canal section is modeled using three reaches from the mouth of the to the Makiki Stream confluence (Lower), from Makiki Stream to the Manoa-Palolo Drainage Canal confluence (Middle), and from the Manoa-Palolo Drainage Canal confluence to the upstream end (Upper). The reach lengths are approximately 2490, 3365, and 4260 ft respectively. The Ala Wai Canal channel has a natural bottom with hardened banks and has tidal influence. Bathymetric data was collected by Oceanit in 2008 and used to compute the cross-section data for the canal.

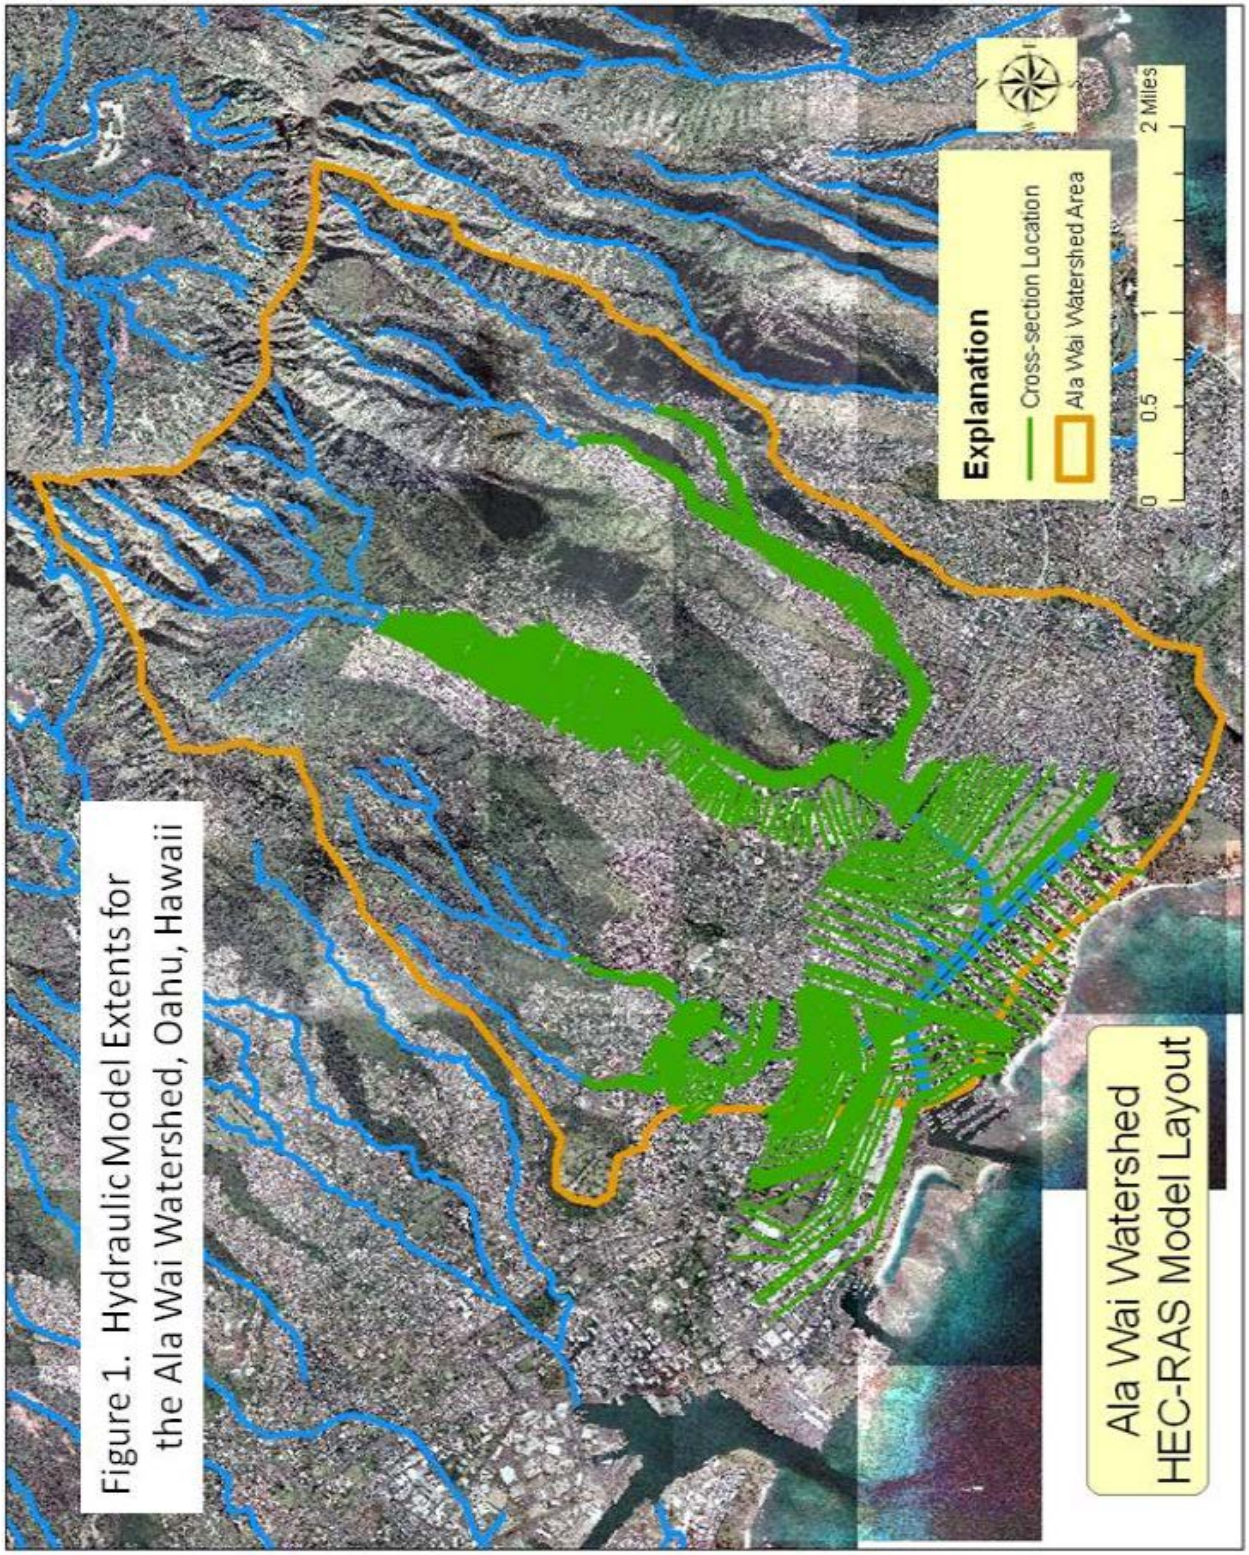

Figure 1: Hydraulic Model Extents for the Ala Wai Canal Watershed, Oahu, Hawaii

3.1.2 Terrain Data

Topographic data for the hydraulic model is primarily based on airborne light detection and ranging (LIDAR) data. The LIDAR data was collected, processed, and verified by Oceanit and their sub consultants in late 2006 and early 2007. The LIDAR data has an accuracy of 45 cm (1.5 ft) horizontal, 37 cm (1.2 ft) vertical and was processed with 1.4 m (5 ft) horizontal point spacing. Datum of data is NAD 1983 HARN projected into Stateplane_Hawaii_3_FIPS_5103_Feet horizontal and mean sea level, local tidal datum, vertical. The current approved National Geodetic Survey (NGS) National Spatial Reference System (NSRS) vertical datum for Oahu is Local Tidal Datum, mean sea level, tidal epoch 1983-2001, geoid 2012A. Horizontal datum is NAD 83 (PA 11). The bare ground LIDAR data was then converted into a Triangular Irregular Network (TIN) format using Geographical Information Systems (GIS) software. The TIN format is needed for using HEC-GeoRAS version 10.1 for ArcGIS version 10.1 to extract the necessary spatial and elevation data for the hydraulic model (*U.S. Army Corps of Engineers, 2011*). The HEC-RAS model schematic layout is illustrated in **Figure 2**.

Elevations used in the hydraulic model were extracted from the TIN. Further refinement to the extracted topographic data especially along and near the stream channels and in other critical areas with large amounts of vegetation overgrowth was done within the HEC-RAS program. Therefore, the Manning's n-values were adjusted and refined where needed. At selected stream cross-section locations conventional land surveys or site investigations and field measurements were done to confirm channel inverts, top of bank locations, bridge dimensions, and other elements relevant to hydraulic modeling. This information was collected and originally entered into the HEC-RAS model by Oceanit and their sub-consultants. Most of the refinements to the cross-sections in the model were based on channel and bridge plans, especially in the Makiki and Palolo areas where the majority of the streams have been channelized. For the upper Manoa Stream area, where much of the stream channel is privately owned, cross-section adjustments were done based on field observations or measurements and not surveyed cross-sections. Cross-section data in the Ala Wai Canal were based on the bathymetric survey data collected in 2008.

3.1.3 Cross-Section Modeling

Cross-section locations for the HEC-RAS model were determined by the channel slope, channel shape, and location of structures. In general cross-sections were spaced about 100 to 500 feet apart for the Ala Wai and Manoa-Palolo Drainage Canals, about 25 feet apart for the Lower Makiki Stream and Palolo Stream Main reaches, and about 50 to 100 ft apart for all the other stream reaches. Near hydraulic structures, such as bridges and culverts, cross-sections were located closer together. Cross-sections in the area of stream confluences or junctions had to be modified to prevent the cross-section lines from crossing each other. These cross-sections were bent, or "doglegged" to insure the overbank areas were not double-counted or were purposely ignored in the case of Makiki Stream near the Ala Wai Canal. Makiki Stream at the mouth of the stream is heavily influenced from the water surface elevation of the Ala Wai Canal. This backwater effect completely overcomes the downstream cross-sections of Makiki

Stream and can give erroneous results if the cross-section length is cut short to avoid crossing any adjacent section lines. For this reason, it was decided to start the Makiki reach just upstream of Kapiolani Blvd. This provided a balance between the influence of the canal water surface elevation and the necessity to properly model more frequent flow events.

Ineffective flow areas were defined at cross-sections to separate areas of active conveyance from adjacent low lying areas that do not contribute to downstream conveyance due to either the presence of high ground along the reach or the expansion/contraction from another control upstream or downstream, such as a bridge or culvert opening. Levee stations were also used to confine flow to channels for lower flow rates especially where the ground elevations were lower than the top of channel. The contraction coefficients for majority of the cross-sections were 0.1, while 0.3 was used near bridges and culverts. The expansion coefficient was set to 0.3 for most cross-sections except near bridges, culverts or lateral structures where a value of 0.5 was used to account for the potential for greater losses.

An important component of hydraulic modeling is the selection of Manning's n-values (roughness coefficients). Manning's n-values were determined from previous studies and several site surveys conducted by Oceanit to characterize the channel roughness. Reasonable values are usually determined from site visits and the use of guides such as Barnes (*1967*) or Arcement (*1989*). Manning's n-values were further refined based on model calibration. Previous modeling on Manoa Stream (*Oceanit, 2008b*) was calibrated to the 2004 flood event on Manoa Stream. Previous modeling of the Ala Wai Canal (*U.S. Army Corps of Engineers, 2001 and 2005*) was calibrated to the limited data of the 1967 event on Palolo Stream and Manoa-Palolo Drainage Canal. Makiki and Kanaha Streams do not have any calibration or gaged data to aid in calibration or model comparison, but are mostly concrete lined channels so the n-values should be stable. Calibrated n-values are assumed to also account for any sediment or debris "bulking" during those storm events. Manning's n-values for the Ala Wai Canal Watershed HEC-RAS model are presented by modeled River and Reach in **Table 1**.

The range of Manning's n-values used can be roughly characterized by channel description. Natural stream channels with minimal vegetation in the channel, steep banks, trees and brush on banks, and bottoms consisting of gravels, cobbles, and few large boulders were given values from 0.03 to 0.04. Natural channel sections that were uniform and contained smooth graveled beds were given a value of 0.025. The Ala Wai Canal was given an n-value of 0.03. Lined or concrete channels were given a value of 0.018 and smooth overbank areas in parks or the golf course were given values of 0.06. The majority of overbank areas in mixed urban areas or overland flow (split flow) areas were given values of 0.1 to 0.125. Previous channel n-values used were 0.04 for the natural channels with 0.06 for all overbank areas (*M&E Pacific, 1977*) to 0.027 to 0.04 for the Ala Wai Canal and 0.25 for the urban overbank areas (*U.S. Army Corps of Engineers, 2005*).

3.1.4 Bridge and Culvert Modeling

Geometric data (culvert diameters and dimensions, culvert length, bridge span, etc.) for all bridges and culverts was obtained by Oceanit and entered into the HEC-RAS model. In many cases, like along Palolo Stream, bridges over concrete channels do not constrict the flow until the flow overtops the banks and thus, have minimal impact to

most of the smaller flow frequency results. In other cases, like Woodlawn Drive Bridge in Manoa, a significant constriction occurs at the smaller flow frequency results. The HEC-RAS model results take these factors into account. A list of bridges and culverts are presented in **Table 2**.

For the Ala Wai Canal Watershed HEC-RAS model all bridges and culverts were modeled using the energy method for low flow if no bridge piers were present. Where bridges had piers, the energy and momentum method was selected and the highest energy answer was then used in the HEC-RAS model for the resulting computations. For the momentum method, the coefficient of drag for the piers was 1.20 at all piers except 1.60 was used at East Manoa Road and Waialae Avenue Bridges, 2.0 was used at the double box culvert at 10th Avenue. For situations where the water surface elevation reaches the low chord of the bridge, the pressure and weir method was selected at all bridges except for those bridges crossing the Ala Wai Canal, Manoa-Palolo Drainage Canal, and Dole Street Bridge on Manoa Stream which used the energy only method due to the flat slopes of these reaches or in the case of Dole Street, where the low chord was 10 feet higher than the 0.2-percent ACE flood elevation.

For determining blocked bridge potential from debris, both from large boulders or floating vegetation, the type of bridge, bridge location, and historical performance was used to determine the percent blockage which was used for all flow modeling. In general, concrete lined channels with supercritical flow tend to wash debris downstream quickly and maintain a “self-cleaning” condition. Most urban debris and trash is small in size with bicycles being the largest observed. Such sized debris has a low potential to create a blockage. In small steep channels, large vegetative debris also has low potential for downstream movement as such debris gets trapped or lodged across the channel and only after being broken up by the force of water will smaller pieces begin to be transported downstream.

The first bridge or culvert in the HEC-RAS model below the forest reserve or undeveloped areas was given a 25% reduction in open area blockage to represent the potential for sediment or debris to constrict these openings. Other percent reductions used were 15% and 45% (see **Table 2**). Two bridges in Manoa, East Manoa Road and Woodlawn Drive have had serious debris problems during the 2004 flood event so were given blocked areas equivalent to those determined from that event. All blockages were modeled in the HEC-RAS model by creating obstructions to a height from the channel bed to an elevation that represents the percent reduction in area. This was done by culvert blockage routines for culverts or cross-section obstructions for bridges in the HEC-RAS model.

3.1.5 Peak Flow Data

Peak flow data from the Manoa and Ala Wai hydrologic studies (*Oceanit, 2008a and 2008d*) were used after adjusting these peak flow values with updated rainfall-frequency data at the hydrologic model junctions, see Appendix A1. The peak flow frequency data was then adjusted from the hydrologic model junctions to corresponding cross-section locations in the HEC-RAS model where the flow would enter the stream channel

in order to capture the change in flow that would occur during each of the frequency based events. There were areas where flow left the main stream channel and followed a new path downhill. To account for these split flow areas, lateral weirs were set to enter the split flow reach at specific stream stations. The HEC-RAS program calculates the weir flow leaving the stream and into the split flow "stream" channel. In the flow file the initial flow for the split flow reaches were set to 1 cubic foot per second (cfs) and the split flow optimization algorithm was used to balance the amount of flow being diverted depending on the value of the peak flow frequency. The peak-flow values used and the input model locations are presented in **Table 3**. The 1-percent ACE peak flow for the Ala Wai Canal in this model was 19,500 cfs. Previous estimates of the 1-percent ACE peak flow value at the mouth of the Ala Wai Canal have ranged from 22,900 cfs (*Edward K. Noda and Associates, Inc., 1994*) to 28,200 cfs (*Federal Emergency Management Agency, 2004*).

3.1.6 Split Flow Assumptions

During the development of the Ala Wai Canal Watershed HEC-RAS model, potential locations where peak-flow discharges leave the defined stream channels and do not return were identified by model results, previous models (U.S. Army Corps of Engineers, 2005) or from knowledge of previous flood events. These locations were modeled in HEC-RAS through the use of lateral weirs (structures) and the split-flow optimization routine in steady flow models. In sections of the model where overtopping flow would move parallel to the stream channel or downhill, no lateral weirs were used. Two locations, along Kanaha and Manoa Streams, were modeled as "stream reaches" to account for the floodplain impacts of these flows and at Waikiki the flow was allowed to leave the model to go into the ocean. The use of split-flow optimization reduces the flow in the stream channel downstream of the lateral weir location if peak-flows leave the channel.

Kanaha Ditch is a cross slope man-made drainage channel that carries runoff to Makiki Stream. Between Nehoa Street and Lewalani Drive flood waters in the model overtop the right bank (looking downstream) and would tend to flow away from the ditch to the south (Figure 3).

A number of lateral weirs were created in the HEC-RAS model along the right bank of the Kanaha Ditch Reach. Those weirs were set at the top of the right bank elevations of the ditch and the overflow was assigned to specific cross-sections in the split-flow reach where it was presumed to flow. Weir flow coefficients were set to 1.0. For all lateral weirs in the model, the weir flow coefficient was determined depending on the round roughness conditions near those areas which would represent the most likely overflow conditions. The Kanaha Split reach extends about 2,600 ft down slope past Wilder Avenue to the H-1 Freeway area. Elevation data provided indicates that the flood extent would not cross the freeway. The model of this split flow reach does not account for the collection of the overtopping flows to be collected by the local storm drain system.

The Manoa Stream split flow reach is called the UH Split reach in the model. This reach was added along Manoa Stream up- and downstream of Woodlawn Drive Bridge. Lateral weirs were added along the right bank of Manoa Stream to account for the overtopping flows which inundated the University of Hawaii campus in 2004. Weir flow coefficients were set at 2.0. The UH Split reach extends for about 6,900 ft from Woodlawn Drive to the lower campus quarry area where it is assumed that the flow would pond and not flow back into Manoa Stream or to the Manoa-Palolo Drainage Canal. Again, in the model this split-flow reach does not account for the collection of the overtopping flows in the reach to be collected by the local storm drain systems.

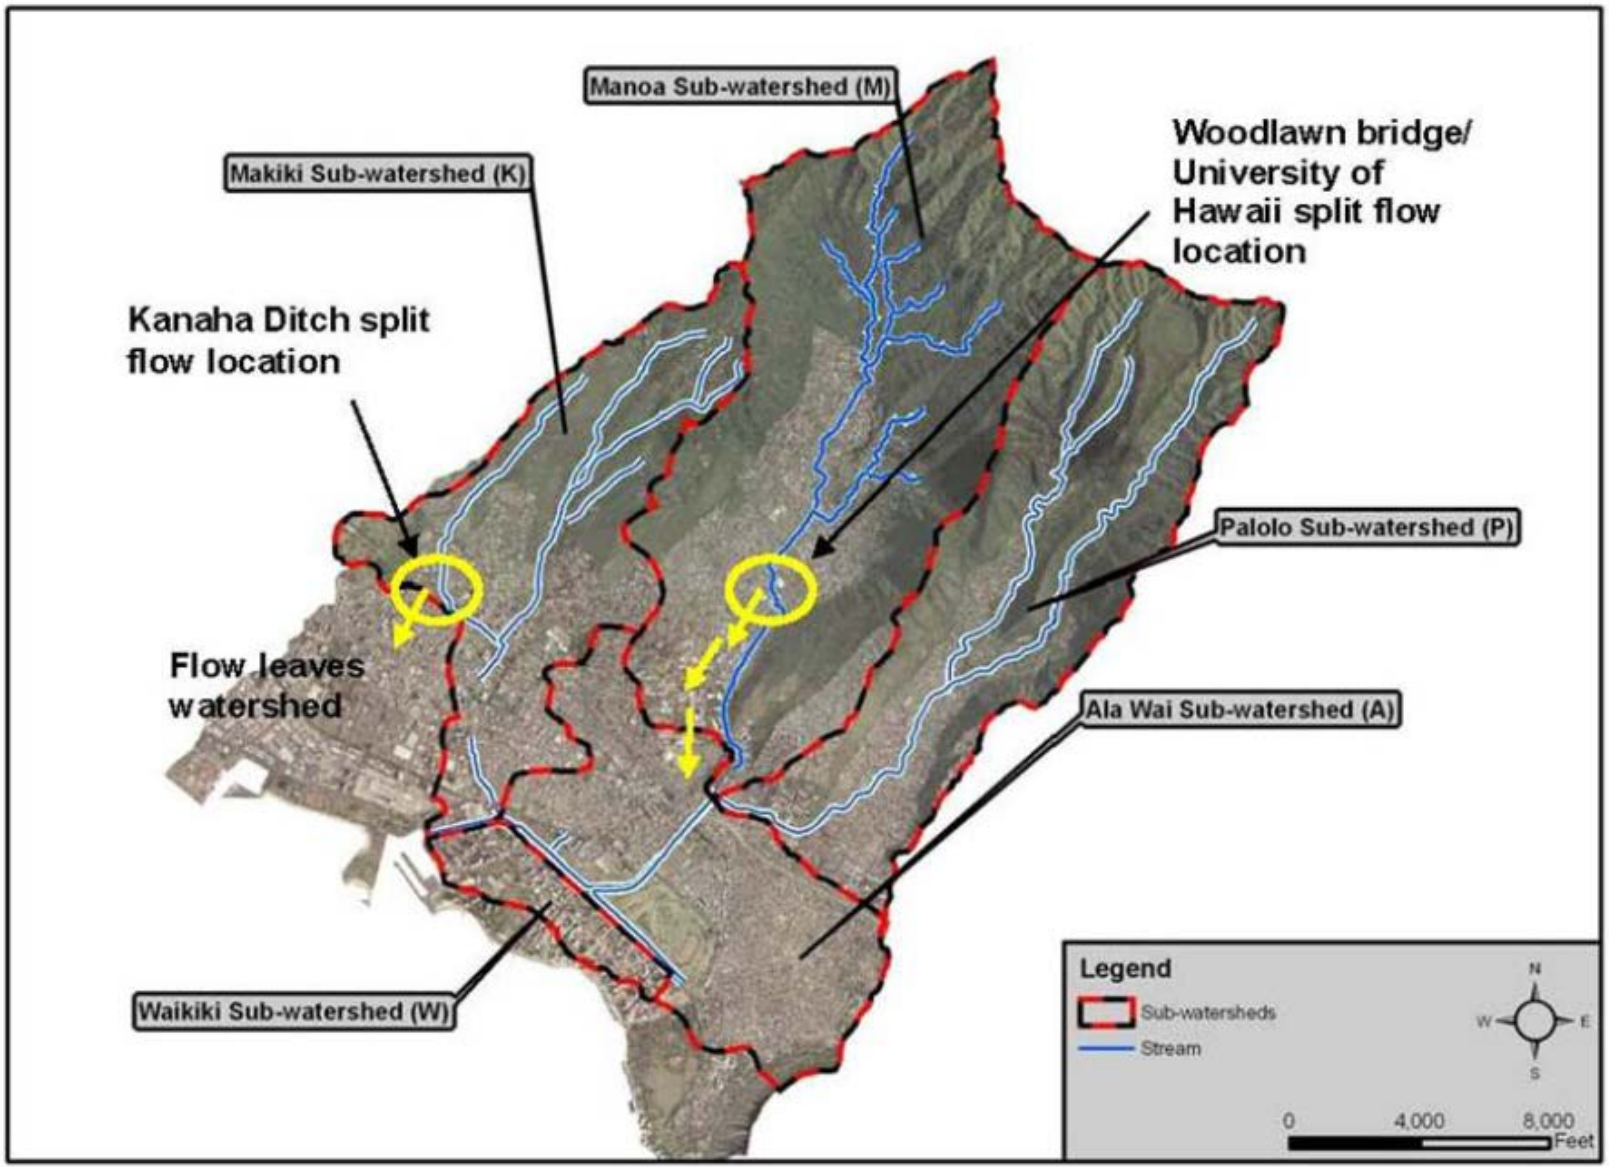

Figure 3: Location of the Split Flow Reaches in the Ala Wai Canal Watershed, Oahu, Hawaii

Along the left overbank of the Ala Wai Canal, from its upstream end down to about McCully Street, flow overtops the “ridge-line” along Waikiki and leaves the model by entering the ocean. This overtopping of the natural topography begins to occur at approximately elevation 6 feet. The flow leaving the system effectively reduces the discharge in the lower end of the canal. To account for the overtopping, lateral weirs were inserted into the model along the Middle and Upper Ala Wai Canal Reaches. Since these weirs are located in an urban environment, weir flow is influenced by the proximity of buildings, automobiles, etc. A weir coefficient of 1.0 was used here. The lateral weirs were set to allow the flow to leave the system (model).

The table below shows all of the lateral structures, the 10-, 2-, 1-, and 0.2-percent (10-, 50-, 100-, and 500-Year) ACE events are shown. The flow upstream (Q US), total flow leaving the structure (Q Leaving Total), and the downstream flow (Q DS) are shown in this table.

3.1.7 Boundary Conditions

Since the Ala Wai Canal Watershed HEC-RAS model is a steady state hydraulic model, only peak flow data and boundary conditions for each event to be modeled were required. In a steady flow model, peak-flow hydrographs traveling from one stream to the next are assumed to occur peak to peak. Boundary conditions for upstream junctions or tributary streams are based on the model results from the downstream reach. The downstream boundary condition for the entire model is the mouth of the Ala Wai Canal where the starting water-surface elevation of 1.08 feet which is the Mean Higher High Water (MHHW) level at the Honolulu Harbor tide gage. The starting water surface elevation at the canal mouth was changed to incorporate sea-level rise in the

future and the inter-annual variability of the tidal data of 0.4 feet. The computed sea-level rise values in Appendix A3 were added to the MHHW water-surface elevation for the modeling of the sea-level rise scenarios (Table 5). The starting water-surface elevation for the Kanaha Split reach was set to normal depth (slope=0.0171). The starting water-surface elevation for the UH Split reach was set to normal depth (slope=0.0001). The starting water-surface elevations for the remaining streams were determined as a result of the hydraulic calculations of the stream junctions. All junctions were set to compute water-surface elevations using the Energy Method.

Table 5. Starting Backwater Values in Feet at the Ala Wai Canal Mouth in the HEC-RAS Model for the Ala Wai Canal Watershed, Oahu, Hawaii

Year	Condition	Low Sea Level Rise	Intermediate Sea Level Rise	High Sea Level Rise
2025	Base	1.64	1.74	2.05
2075	Future/Design	1.89	2.50	4.44
2125	Future	2.14	3.71	8.69

4 WITHOUT PROJECT MODEL RESULTS AND FLOOD INUNDATION MAPPING

The HEC-RAS model was used to determine the water-surface elevations and floodplain extents for the 50-, 20-, 10-, 5-, 2-, 1-, 0.5-, and 0.2-percent ACE floods (2-5-, 10-, 20-, 50-, 100-, 200-, and 500-year recurrence intervals). Floodplain extents for the 10-, 50-, 100-, and 500-year recurrence intervals are shown on **Figures 4** through **7**. The water-surface elevation data for the 8 flood events are used in the HEC-FDA (Flood Damage Analysis) program to determine flood damages for the economic analyses. The HEC-FDA program uses the water-surface elevations in determining flood damages and not the flood maps, so any irregularities in the presented maps has no impact on the damage calculations.

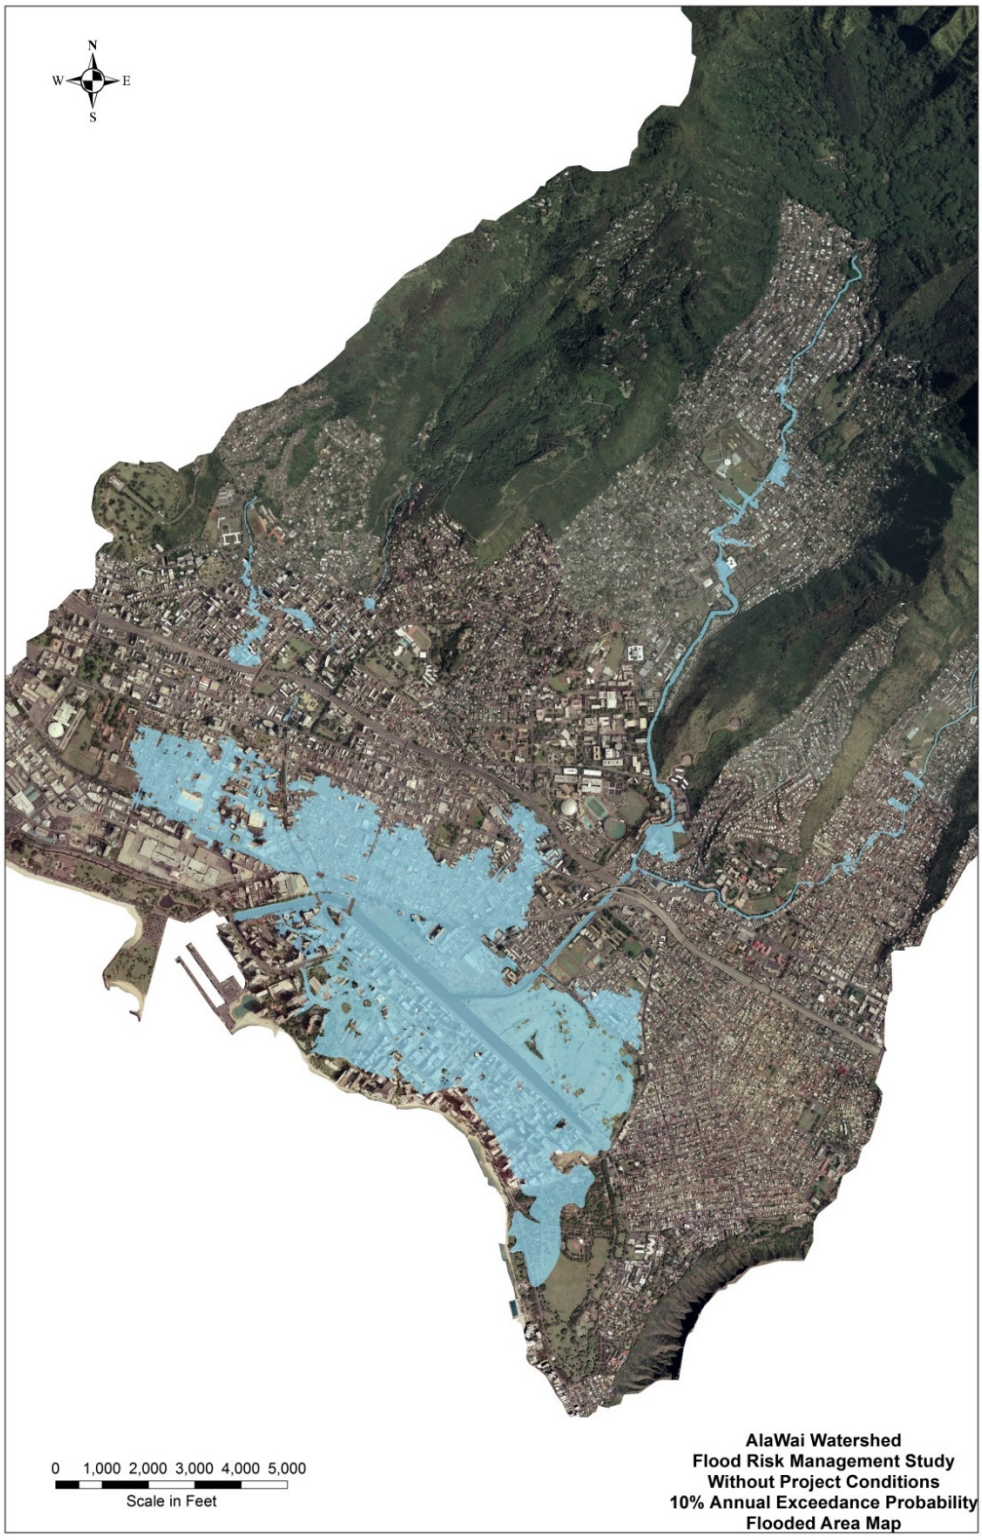

Figure 4: Floodplain Outlines for the 10-Percent ACE (10-year) Flood, Ala Wai Canal Watershed, Oahu, Hawaii.

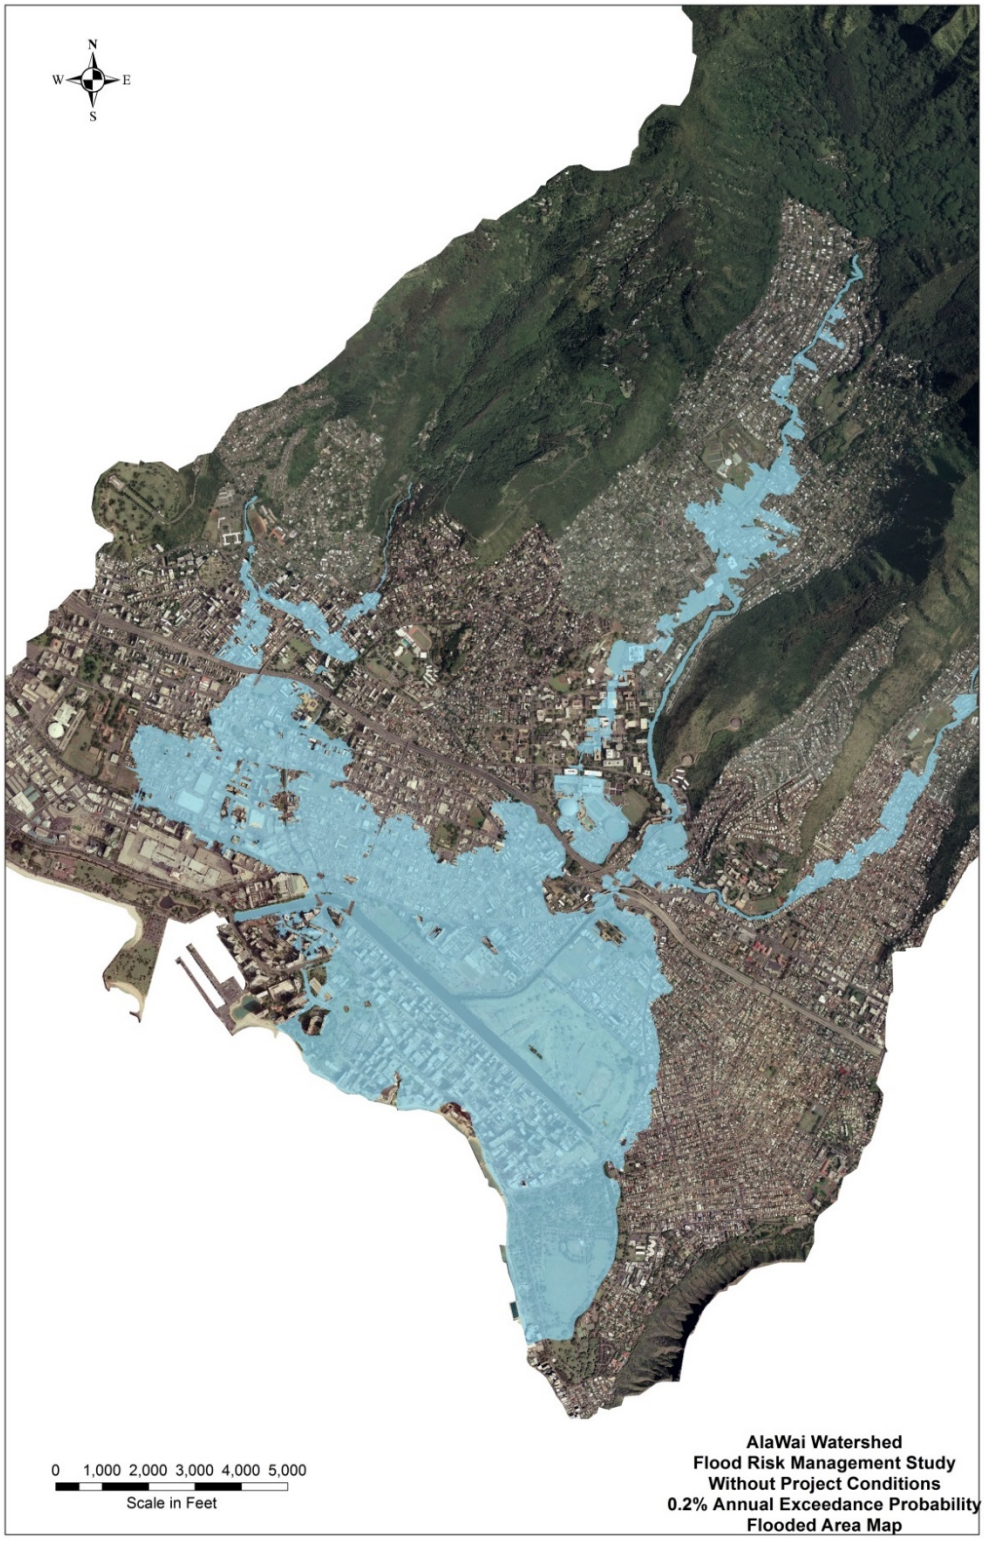

Figure 7: Floodplain Outlines for the 0.2-Percent ACE (500-year) Flood, Ala Wai Canal Watershed, Oahu, Hawaii.

4.1 Model Limitations

The HEC-RAS model was designed as a steady flow model using a mixed flow regime solution. As such, a number of warning messages appeared in several reaches indicating an unbalanced solution at cross sections resulting in critical depth or non-convergence. In steep reaches this message typically indicates the model is defaulting to critical depth because a super-critical flow answer is possible. The subcritical regime provides a conservative estimate of water-surface elevations for evaluating flooding but a mixed flow solution is more accurate. A mixed flow regime uses both subcritical and supercritical regimes. In less steep reaches, the primary reason for warning messages is probably due to the sharp contrast in Manning's n values between the channel at 0.018 to 0.04 and the overbanks at 0.125. The convergence problem seems to be most pronounced at bridges and culverts where the bridge deck and presence of weirs complicate the model solution process. Slight adjustments to ineffective flow limits helped reduce the non-convergences, but there are some locations where the messages could not be avoided for all storm events. One such location is the Makiki Stream between Anapuni Street and Wilder Street (cross sections 6316 to 5952).

Other warning messages such as conveyance ratios exceeding the 0.7 to 1.4 guidelines, velocity head differences exceeding 0.5 feet (ft) and energy losses greater than 1.0 ft between cross sections are due to the cross section geometry of the study area and cannot be avoided. Cross-section spacing can help with the steady flow solution. Average cross-section spacing for the various reaches in the Ala Wai Canal Watershed HEC-RAS model is presented in **Table 6**. In general, cross-section spacing from 50 to 100 ft in steep reaches and from 250 to 750 ft in flat reaches is adequate. In concrete channels such as Makiki Lower and Palolo Main reaches cross-sections were spaced at least 25 ft apart, this is to gain accuracy.

The use of split flow reaches to model areas where there is no flow under normal conditions are difficult to model accurately. The HEC-RAS model as with all hydraulic models, require a flow value to be used for each reach. Zero flow is not an allowable input value. For the Kanaha and UH Split reaches a flow value of 1 cfs was used as the initial input. Even with just a 1 cfs flow there will be a water-surface elevation, when in some cases there should be no water at all. For the 50- to 10-percent ACE floods, when flow is not leaving the main channel, the model results would indicate flood depths, although very low, when none would be present. This is a model artifact which needs to be accounted for when making flood inundation maps or using the data in HEC-FDA. For HEC-FDA, the water-surface elevation input data was changed to ground elevation at certain locations and flood events based on logic.

Split flow optimization was used to allow HEC-RAS to calculate lower flows in the main channel in locations where lateral weirs allow the flow to leave the main channel. Because there are multiple lateral weirs in the model, and in some locations multiple connection, such as the golf course reach, split flow optimization failed to converge. If split flow optimization is not used, results can be more conservative.

Table 6. Cross-section Spacing in the Ala Wai Canal Watershed HEC-RAS Model, Oahu, Hawaii

HEC-RAS River, and Reach Names	Average Cross-section Spacing in Feet
Ala Wai Canal, Upper, Middle, and Lower	286
Kanaha, Ditch (includes interpolated)	47
Kanaha, Split	87
Makiki Stream, Upper	107
Makiki Stream, Lower	31
Manoa Stream, Main	61
Palolo Stream, Main	96
Palolo Stream, Lower (includes Manoa-Palolo Drainage Canal)	180
Pukele Stream, Tributary	97
UH_Split, UH_Split	160
Waiomao Stream, Tributary	90

4.2 Flood Inundation Mapping

The flood inundation maps in **Figures 4** to **7** were generated by the HEC-GeoRAS software using TIN (Triangulated Irregular Network) elevation data and the maximum water-surface elevation profiles computed by HEC-RAS. A raster cell size of 5 feet was used to create the inundation outlines. HEC-GeoRAS converts the TIN elevation data and the maximum water-surface elevation data to raster layers with a 5 foot by 5 foot grid size before comparing them to one another. HEC-GeoRAS evaluates whether the water-surface elevation grid has a higher elevation than the ground-surface elevation grid. If the water-surface elevation was higher than the ground-surface elevation, the cell was considered inundated. The results were in raster datasets of the inundation depths. The inundation depth grid was then converted to a floodplain polygon coverage showing the maximum extents of flooding. The automated delineation process creates areas of no inundation, as the example figure, **Figure 8** shows areas or polygons where inundation is included or not included. As you can see in the figure there are some locations where inundation is not connected to the main inundation extents.

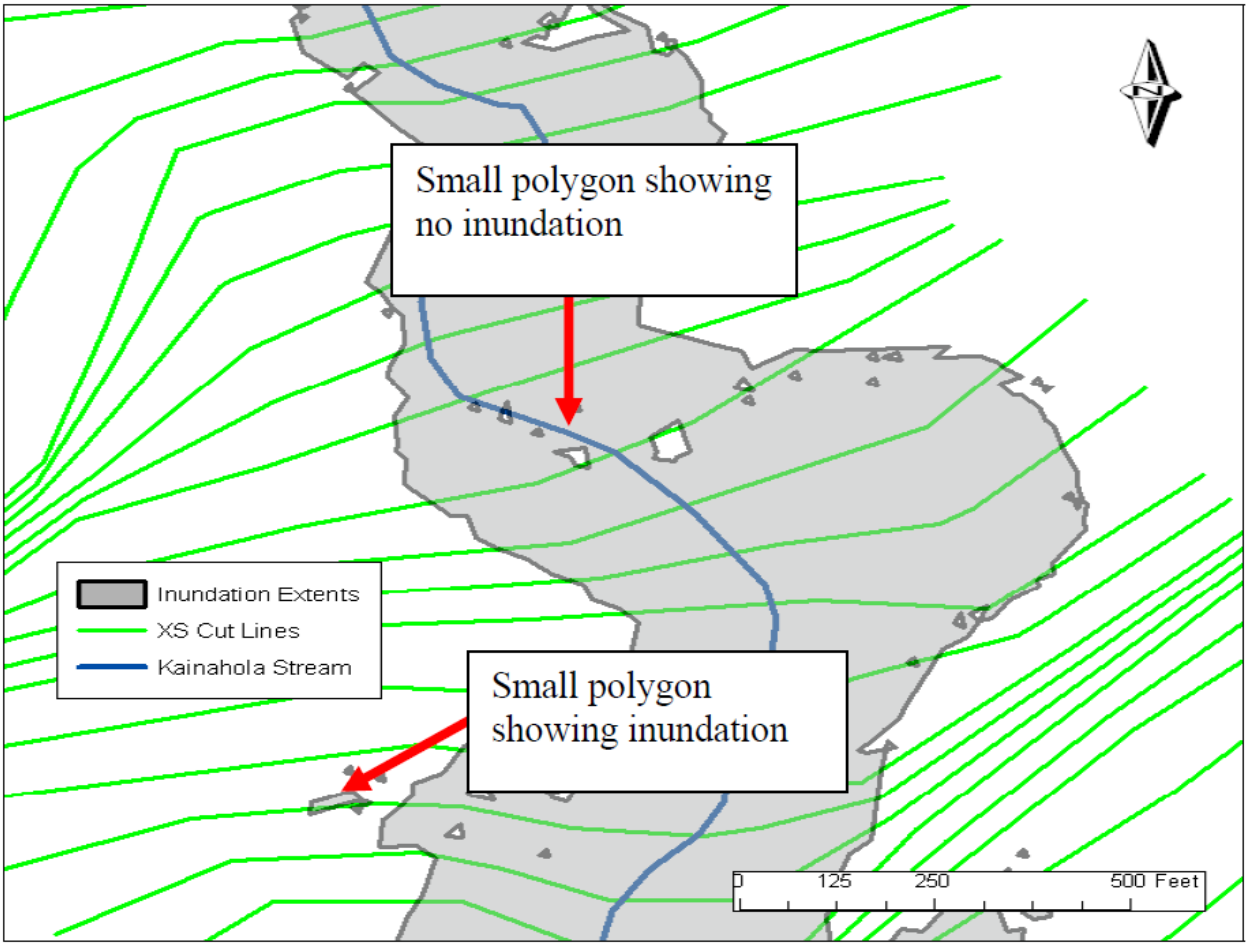

Figure 8: Example of inundation extents coverage created by HEC-GeoRAS.

Some non-connected areas of inundation, as described above, are an initial limitation of the mapping process because the computed water-surface is limited to the extents of the cross-sections; however, final mapping results should involve engineering judgment to modify the floodplain boundaries based on modeling assumptions and topographic data. If floodplain mapping is needed from the model results, then manual edits were done to either fill-in or remove areas where flooding is or is not likely to occur. An example of **Figure 8** with manual edits is shown on **Figure 9**.

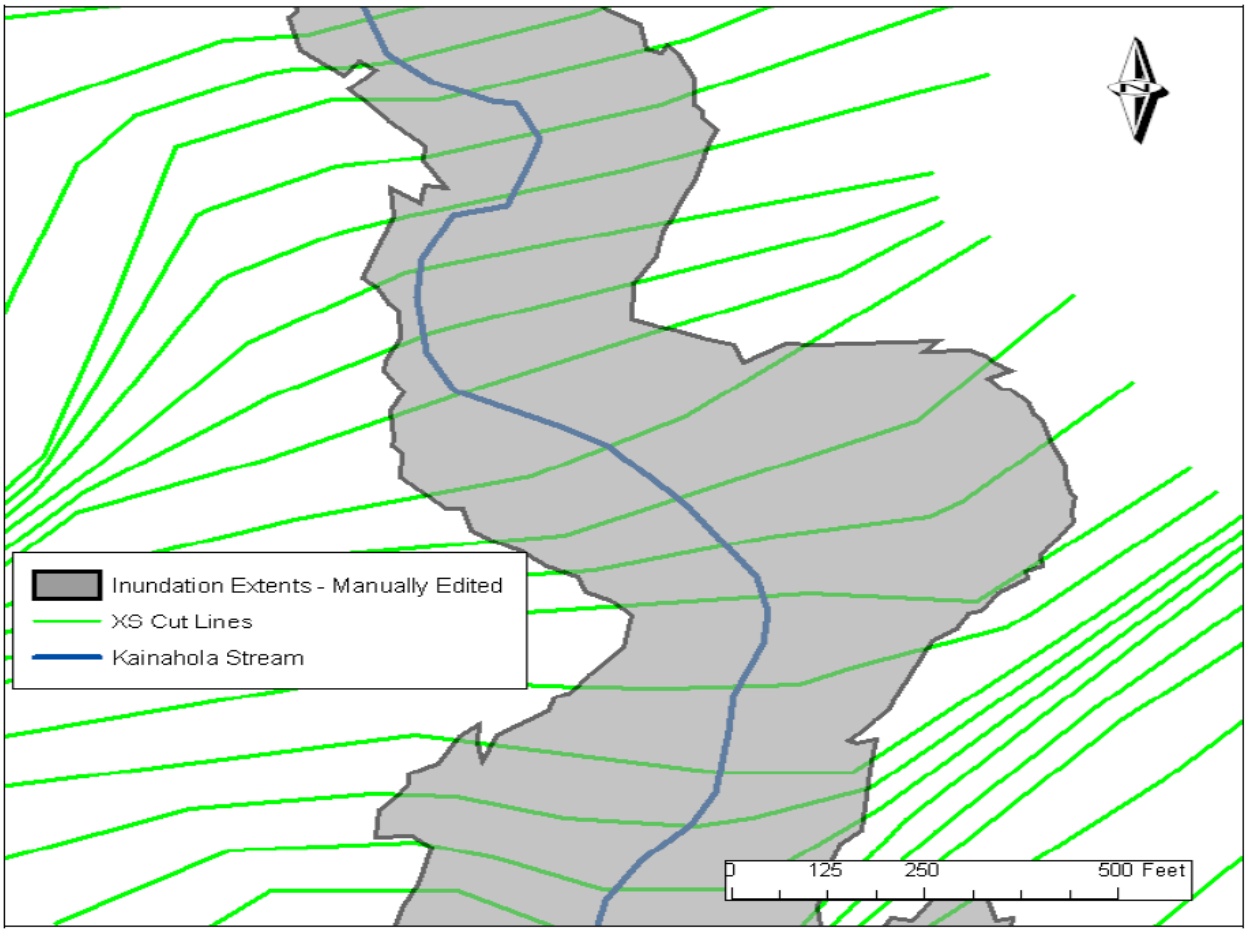

Figure 9: Example of inundation extents coverage manually edited.

4.3 Model Results

The inclusion of the lateral weirs along the Waikiki area of the Ala Wai Canal reaches resulted in a reduction in peak flow downstream of McCully Street at the 1-percent ACE (100-year) flood event; a total of approximately 5,150 cfs leaves the system and flows into the ocean. With consideration of the effects of floodplain storage and backwater along Makiki Stream, the peak flow at the mouth of the canal is reduced to about 12,675 cfs from its upstream peak of 19,500 cfs. This results in a greatly reduced flood inundation area between Kalakaua Ave. and Ala Moana Blvd. Based on the peak flow values computed for this study the Ala Wai Canal has about a 20- to 10-percent ACE (5- to 10-year) flood event capacity before overtopping. This is less than the 10-percent ACE (10-year) flood event capacity documented in Edward K. Noda and Associates, Inc. (*1994*) even with the dredging done in 2008. One reason for a reduced capacity may be due to the use of MHHW as a downstream boundary condition for all flood events and the use of a steady flow HEC-RAS model which tends to be more conservative than the in-house model used by Edward K. Noda and Associates, Inc. (*1994*). The Kalakaua Ave. Bridge was the main reason for high water-surface elevations in the upstream sections of the canal.

The flooding along lower Makiki Stream is mainly due to the high water-surface elevations of the Ala Wai Canal being such that the Makiki Stream cannot drain. Water backs up into Makiki and overtops the channel and floods the surrounding area. The flooding occurs between King St. and Kapiolani Blvd. The elevations along Kapiolani Blvd. are slightly higher than the surrounding ground, and as a result, act as a berm or weir preventing most of the flow from flooding the downstream area. A small area in the vicinity of Kaheka St. allows flow to flow over Kapiolani Blvd. and eventually into the lower area of the parking facility of the Ala Moana Center. Channel capacities for the model reaches are listed in **Table 7**. The split reaches don't have any capacities because they are not actual streams they are just the natural ground. The flooding inundation extents for lower Makiki Stream on **Figures 4** to **7** are somewhat overestimated due to the small existing channel sizes and large floodplain areas modeled. The flood mapping routines will fill in the entire cross-section width even though water may not actually flow into those areas for other factors such as walls and buildings which are not always representative in the model.

Table 7. Approximate Average Bankfull Channel Capacities and Beginning Level of Damages by Annual Probability for Stream Reaches in the HEC-RAS Model for the Ala Wai Canal Watershed, Oahu, Hawaii

River	Reach	Average Bankfull Peak Discharge Capacity (cfs)	Percent Chance Flood	Recurrence Interval (years)
Ala Wai	Lower	12,200	20	5
Ala Wai	Middle	6,900	20	5
Ala Wai	Upper	1,300	20	5
Kanaha	Ditch	350	20	5
Kanaha	Split	N/A	N/A	N/A
Makiki	Upper	1,200	5	20
Manoa	Main	3,500 to 7,600	20 to 2	5 to 50
Palolo	Main	3,400 to 6,000	10 to 2	10 to 50
Palolo	Lower	15,400	2	50
Pukele	Tributary	2,700	2	50
UH_Split	UH_Split	N/A	N/A	N/A
Waiomao	Tributary	2,600	2	50

The flooding along Kanaha Ditch is similar to the flooding along Makiki Stream. The water-surface elevation at the confluence of the ditch causes a backwater effect in the ditch and does not allow it to drain. Water overtops the channel and flows down slope. Water flows across Wilder St. and floods the area approximately bounded by Kewalo St. and Keeamoku St. Water is stopped by the H1 Freeway where it will pond and presumably make its way into the stormwater drainage systems.

Another issue with the flood modeling in the Makiki area is the discharge contained in the stream channel where floodwalls exist. These floodwalls are built upon the stream channel walls (**Photo 1**) and may or may not prove suitable to contain large flood

events. It was assumed in the HEC-RAS model that none of these types of levee-like structures would fail during any of the model runs. **Photo 2** shows that some locations may not prove adequate and the resulting flood inundation areas may be larger than shown on **Figures 4** to **7**.

As can be seen for the flood inundation maps (**Figures 4** to **7**), the floodplain boundaries for the lower Makiki Stream, the Manoa-Palolo Drainage Canal, and the Ala Wai Canal are shown in some areas as reaching the watershed boundaries. This result could be overly conservative if the hydrograph volume is insufficient to produce such flooding. Also, the flood inundation limits reach the model boundary such as at the upper end of the Ala Wai Canal. Flooding at these locations will more than likely flow into Kapiolani Park and then into the ocean. A manually edited map should account for this possibility.

Results of the detailed modeling of Palolo Stream indicate a channel capacity capable of holding a 2-percent ACE (50-year) flood event between Palolo Ave. Bridge and Kahlua Rd. Bridge. The capacity downstream is between the 5- to 2-percent ACE (20- to 50-year) flood events.

As previously documented (*U.S. Army Corps of Engineers, 2005; Oceanit, 2008b*) the Manoa Stream has channel capacity limitations between Kahaloa Drive Bridge and Woodlawn Drive Bridge which creates a flooding hazard for the nearby residences and the University of Hawaii campus.

Flood depths for the 1-percent ACE flood event around the Ala Wai Canal, Manoa-Palolo Drainage Canal, and lower Makiki Streams (**Figure 6**) are about 1.5 to 3 feet deep on average for the out of channel floodplain. Flood depths are about 2 to 3 feet deep on average for the split flow reaches of Kanaha Split and the UH_Split overland flooding. In the upper Makiki, Manoa and Palolo Streams, flood depths can get up to 5 feet depending on the location.

As a check to existing conditions HEC-RAS model computations, a comparison was made at results near USGS gaging stations located in the study area. One difficulty is that the gages are operated using gage datum which does not correspond to a known datum such as mean sea level, and thus, to make this comparison, an approximation of gage datum converted to HEC-RAS model datum, mean sea level, was made based on information supplied by the USGS at their gage locations and the elevation data of the nearest RAS model cross-section. It is expected that this conversion has a 1 foot error and that an additional difference of +/- 0.7 foot would result from model error and USGS gage rating curve error. **Table 8** shows this comparison. The discharge value comparison is based on a common discharge values from the station rating curves and the HEC-RAS model results at that location.

Photo 1. Makiki Stream looking upstream of Fern Street, November 2009

Photo 2. Makiki Stream looking upstream of Fern Street, April 2006 Flood damage to CMU wall built on channel wall from March 31, 2006 storm. Photo by Oceanit.

Table 8. Comparison of Existing Conditions HEC-RAS Model Results with Data from USGS Stream Gaging Stations, Ala Wai Canal Watershed, Oahu, Hawaii.

USGS Gage Station Number	HEC-RAS Model Reach	HEC-RAS cross-section Location	Comparison Discharge Value in ft^3/s	Gage Water Surface Elevation converted to Model Elevation (ft)	HEC-RAS Model Water-Surface Elevation (ft)
16242500	Manoa Main	1230	4,450	36.4 or 38.8	38.07
16247000	Palolo Main	9520	1,200	96.2	95.72
16247100	Palolo Lower	3201	10,910	11.9	12.93

As can be seen from comparison, water surface elevation results fall within the expected error of +/- 1.7 feet. At station 16242500, two water station elevations were computed for the conversion as the data points for the conversion was more vague that at the other two locations.

4.4 Sensitivity and Uncertainty

To test the sensitivity of the model to variation in Manning's "n" values, model runs were made varying the "n" values by +/- 20%. Results of the model runs show that for the upper reaches of Makiki, Manoa, Palolo, Pukele, Waiamao, Kanaha, there was virtually no difference in water surface elevation. This is due to the fact that these reaches are flowing at critical depth or in the supercritical flow regime. The lower reaches of of Makiki and the Manoa-Palolo canal, the difference in water surface was about 0.25 ft. In the UH_split reach, the difference in water surface elevation varied from +/- 0.2 ft. to a maximum of +/- 0.4 ft. On the alaWai canal, the difference ranged from +/- 0.2 feet in the upper reach to +/- 0.4 ft. in the lower reach.

These values were much lower than the minimum values specified in Engineer Manual 1110-2-1619, Risk-Based Analysis for Flood Damage Reduction Studies, (EM 1110-2-1619) provides guidance in determining risk and uncertainty. Table 5-2 of EM 1110-2-1619 provides minimum values for the standard deviation of error in stage. This table is reproduced below as **Table 9**.

Table 9. Minimum Standard Deviation of Error in Stage

Manning's n Value Reliability[1]	Cross Section Based on Field Survey Or Aerial Spot Elevation	Cross Section Based on Topographic Map with 2-5' Contours
Good	0.3	0.6
Fair	0.7	0.9
Poor	1.3	1.5

1- Where good reliability of Manning's n value equates to excellent to very good model adjustment/validation to a stream gage, a set of high water marks in the project effective size range, and other data. Fair reliability relates to fair to good model adjustment/validation for which some, but limited, high water mark data is available. Poor reliability equates to poor model adjustment/validation or essentially no data exists for model adjustment/validation.

As stated in Section 3.1.2, elevation data used in the hydraulic model was obtained from LIDAR data collected in late 2006 and early 2007. The data has an accuracy of 1.5 feet in the horizontal plane and 1.2 feet in the vertical plane. The elevations were processed with a 5 foot point spacing. Spot elevations were developed to a 0.1 foot accuracy.

Manning's "n" values were estimated from field observations and engineering judgement. These values were refined based on model calibration as described in Section 4.3. Due to the limited data available for calibration, the reliability of the Manning's "n" values used can be considered fair.

Using **Table 9** as a guide, the standard deviation was set to 0.7 feet. This factor was applied to all water surface elevations calculated during the model runs.

5 WITH PROJECT HYDROLOGIC MODELING

5.1 Detention Analysis

In order to determine the effectiveness of detention basins throughout the watershed, the HEC-HMS model, the Technical Summary Report, Manoa Watershed Project (*Oceanit, 2008c*), and other hydrologic analysis were used to study different detention basin scenarios.

5.2 Preliminary Analysis

Initially, 12 different sites were selected throughout the watershed. **Figure 10** shows the locations of the proposed detention basins. Each detention basin was designed to maximize effectiveness while remaining within reasonable vertical and horizontal limitations. Each basin was examined to determine the potential flow reduction. Basins were analyzed for all eight storm events.

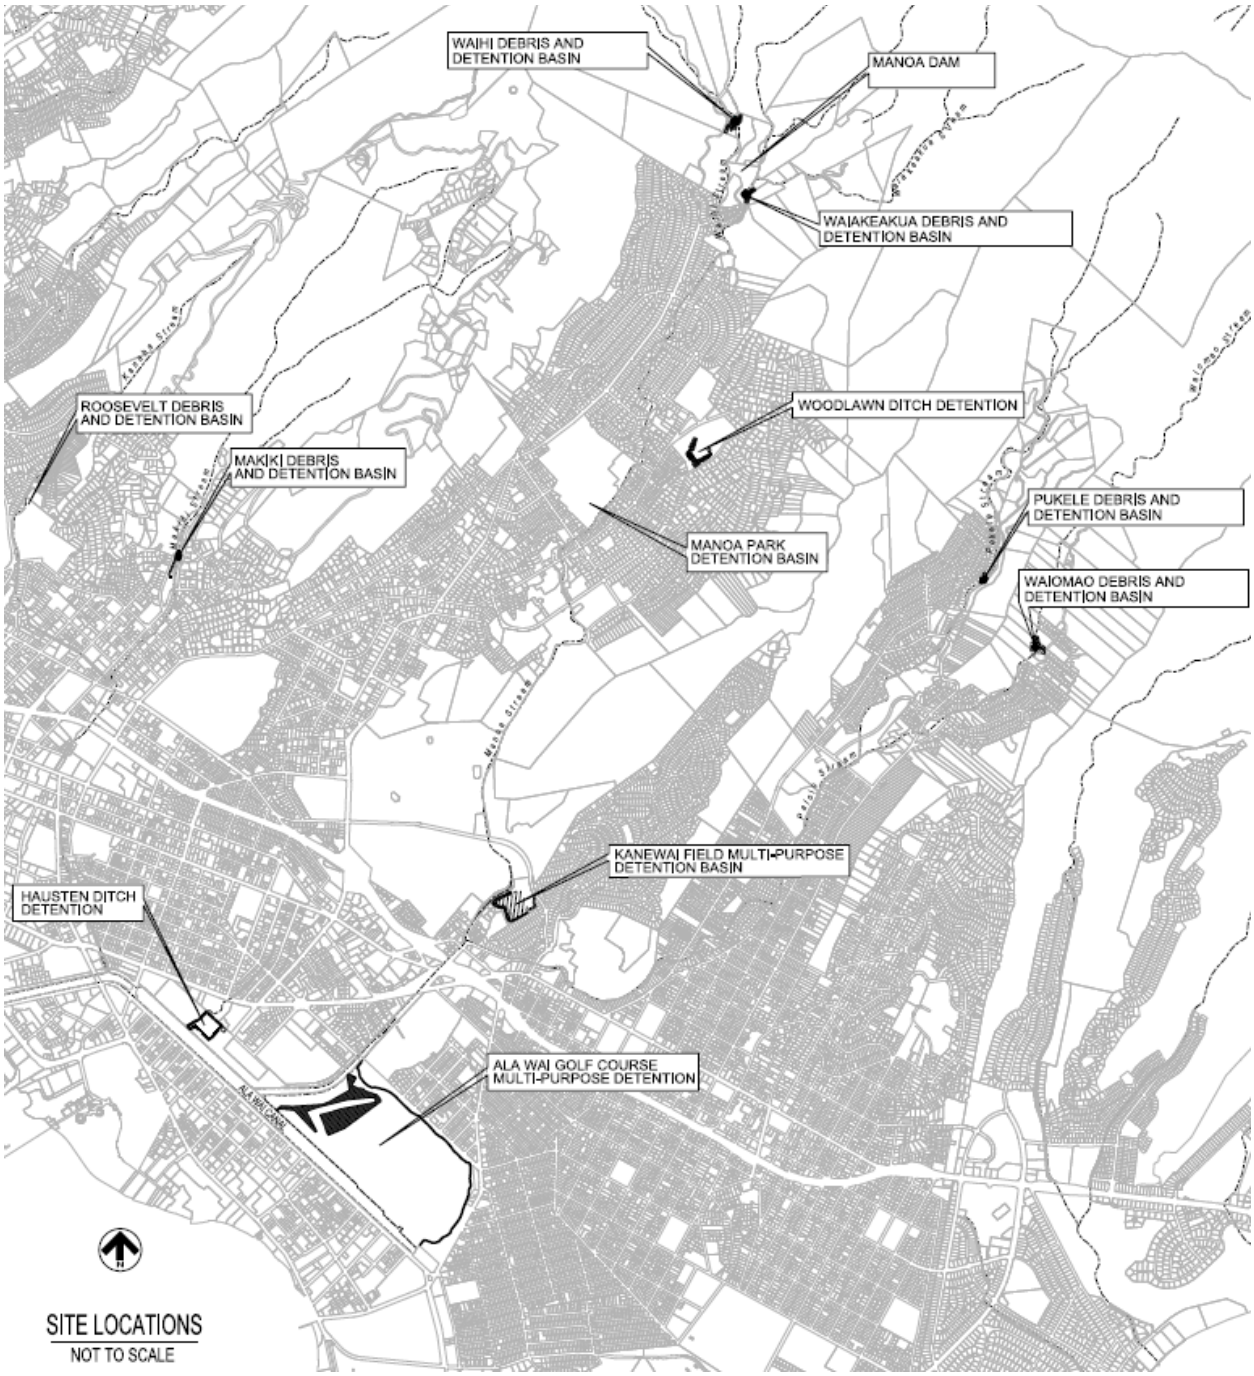

Figure 10: Preliminary Detention Basin Locations

Roosevelt Debris and Detention Basin

This basin is designed as both a way to temporarily contain water and stop the flow of debris into Kanaha Stream. The design assumes a downstream capacity of 1,254 cfs and 20 foot high berms with an emergency spillway. The basin is not designed to permanently contain water, but to detain large volumes of water to slow the rate into

Kanaha Stream. In addition, the basin is designed to use existing open space (i.e. no residential houses). There is an arch culvert under the berm; it is 12' long and 4'-1" high. The outlet allows about 946 cfs to pass through into Kanaha Stream.

Makiki Debris and Detention Basin

This basin is designed as both a way to temporarily contain water and stop the flow of debris into Makiki Stream. The design assumes a downstream capacity of 450 cfs and 24 foot high berms with an emergency spillway. The basin is not designed to permanently contain water, but to detain large volumes of water to slow the rate into Makiki Stream. In addition, the basin is designed to use existing open space (i.e. no residential houses). There is an arch culvert under the berm; it is 12' long and 4'-1" high. The outlet allows about 390 cfs, the 20-percent ACE (5-year) storm, to pass through into Makiki Stream.

Hausten Ditch Detention

This basin is designed to temporarily contain water while the slide gates at Hausten Ditch Bridge are up. The slide gates will be down during a flood event to prevent water from Ala Wai Canal flowing back into Hausten Ditch. In addition, the basin is designed to use existing open space (i.e. no residential houses).

Ala Wai Golf Course Multi-Purpose Detention

This multi-purpose detention basin is designed to contain water on the golf course and prevent flood waters from leaving. There will be earthen berms constructed on the north and east sides of the golf course, the berms will basically follow the existing golf cart road. The berms have an average height of 3 feet.

A sediment basin would be located in the vicinity surrounding holes 12 to 18 of the Ala Wai Golf Course. Flows from the Manoa-Palolo Drainage Canal would be diverted into the sediment basin, which would help reduce the amount of sediment deposited into the Ala Wai Canal. Flows would reenter into the Canal at two locations, a new outlet connected to the sediment basin and an existing outlet.

Manoa Dam

This dam is designed to contain all of the predicted upstream storm water. Through modeling and rain data, it was determined that the dam needed to retain about 17,000,000 cf of water behind the residential neighborhoods of Manoa. This large quantity of water severely restricted the dam location and forced a maximum height of 50 feet. Two spillways capable of handling 3,450 cfs each located above the river bed. The spillways were sized to allow overflow for a 0.2-percent ACE (500-year) storm, with a peak flow of 6,900 cfs. There are two outlets, one into Waihi Stream and one at the junction of Luaalea and Waiakeakua Stream. The Waihi Stream 5x7 foot culvert has a capacity of 1,770 cfs and the Waiakeakua Stream 5x6 foot culvert has a capacity of 1,890 cfs, representing flows from a 20-percent ACE (5-year) storm. Flows greater than this will cause water to back up and be retained behind the dam (*Oceanit, 2008c*). In

addition, the structure is to not interfere with existing farms and houses near the basin site.

Waihi Debris and Detention Basin

This basin is designed as both a way to temporarily contain water and stop the flow of debris into the Manoa residential area. The design assumes a maximum downstream capacity of 3,000 cfs and a maximum 24 foot height and minimum containment of 125,000 cubic feet. The basin is not designed to permanently contain water, but to detain large volumes of water to slow the rate into Manoa Stream. In addition, the structure is to not interfere with existing farms and houses near the basin site.

There is an arch culvert under the berm; it is 12' long and 4'-1" high. The outlet allows about 2,000 cfs, the 20-percent ACE (5-year) storm, to pass through into Manoa Stream. The emergency spillway would begin to overflow when the retention capacity of 125,000 cf is exceeded.

Waiakeakua Debris and Detention Basin

This basin is designed as both a way to temporarily contain water and stop the flow of debris into the Manoa residential area. The design assumes a maximum downstream capacity of 3,000 cfs and a maximum 20 foot height and minimum containment of 346,000 cubic feet. The basin is not designed to permanently contain water, but to detain large volumes of water to slow the rate into Manoa Stream. In addition, the structure is to not interfere with existing farms and houses near the basin site.

There is an arch culvert under the berm; it is 12' long and 4'-1" high. The outlet allows about 1,475 cfs, the 20-percent ACE (5-year) storm, to pass through into Manoa Stream. The emergency spillway can handle an extra 3,150 cfs should such high flows occur.

Woodlawn Ditch Detention Basin

The basin is not designed to permanently contain water, but to detain large volumes of water to slow the rate into Woodlawn Ditch will eventually flow into Manoa Stream. The design assumes a maximum downstream capacity of 2,750 cfs and a maximum 20 foot height, there is also a 3x80 foot concrete-lined emergency spillway. The design assumes that slightly less than 750 cfs will flow into Woodlawn Ditch while the remaining flow will be contained in the detention basin during a flood event.

There is an arch culvert under the berm; it is 12' long and 4'-1" high. The outlet allows about 977 cfs out into Woodlawn Ditch.

Manoa Park Detention Basin

The basin is designed to use existing open space (i.e. no residential houses, use of park land) to create a detention basin that is both useful and aesthetically pleasing to the community. The detention basin is designed to handle an inflow of 4,250 cfs;

additional flows up to 2,490 cfs will require the use of the emergency spillway. The berm has a maximum eight of 13 feet and it would border three sides of Manoa District Park. The intake pipes from Poelua Place lies underground and has a bubble-up structure located in the south east corner of the park, covered by a concrete pad to ease in clean-up procedures. The bubble-up structure intakes both 10x10 foot box culverts and has a 2 foot diameter concrete outlet pipe for slow drainage back into Manoa Stream. Any water that does not immediately drain is bubbled into the basin. The basin has graded contours to allow water to accumulate to the southeast corner of the park at the drainage. For aesthetics and for clean-up the three surrounding berms have bleachers on the inside. The new landscaped park has room to contain two baseball fields and a soccer field.

Kanewai Field Multi-Purpose Detention Basin

The basin is designed to use existing open space (park land) to temporarily contain floodwaters. The intake into Kanewai Field is intended to handle 3,960 cfs of the stream inflow and outflow. The existing drainage pipe is able to drain 62 cfs. Kanewai Field will be surrounded by a 7 feet high earthen berm, but protecting the existing structures. On the northwest end of the basin, adjacent to Manoa Stream, the berm is graded down to a 3x60 foot spillway that will allow water to flow into the basin when the river level is high and out of the basin once the high flows have passed.

Pukele Debris and Detention Basin

This basin is designed as both a way to temporarily contain water and stop the flow of debris into Pukele Stream. The design assumes a downstream capacity of 1,700 cfs and a 24 foot high berm with an emergency spillway. The basin is not designed to permanently contain water, but to detain large volumes of water to slow the rate into Makiki Stream. There is an arch culvert under the berm; it is 12’ long and 4’-1” high. The outlet allows about 300 cfs, to pass through into Pukele Stream.

Waiomao Debris and Detention Basin

This basin is designed as both a way to temporarily contain water and stop the flow of debris into Waiomao Stream. The design assumes a downstream capacity of 1,540 cfs and a 24 foot high berm with an emergency spillway. The basin is not designed to permanently contain water, but to detain large volumes of water to slow the rate into Makiki Stream. There is an arch culvert under the berm; it is 12’ long and 4’-1” high. The outlet allows about 400 cfs, to pass through into Pukele Stream.

6 WITH PROJECT HYDRAULIC MODELING

6.1 Detention Analysis

For each of the detention scenarios modeled (See With Project Hydrologic Modeling Section) the HEC-RAS model was modified with the revised flows.

6.2 Debris Catchment Analysis

In order to determine the effectiveness of debris catchments throughout the watershed, the HEC-RAS model, the Technical Summary Report Manoa, Watershed Project (*Oceanit, 2008c*), and other analysis were used to study different debris catchment scenarios.

6.2.1 Preliminary Analysis

Initially, 7 different sites were selected throughout the watershed. **Figure 11** shows the locations of the proposed debris catchment sites. Each debris catchment was designed to maximize effectiveness while remaining in a viable location within reasonable vertical and horizontal limitations.

Waiakeakua Debris Catchment

This structure is designed to catch large debris. It allows all flood flows to pass through the debris poles. It is assumed that the largest river flow will be below the maximum height of the poles and will span the length of the debris catchment structure. The structure consists of a 2-foot thick concrete pad that spans 140 feet across the stream and the floodplain with a width of 8 feet. Steel posts 8 inches in diameter and between 4 to 7 feet high are evenly spaced at 4 feet along the center of the concrete pad.

Waihi Debris Catchment

This structure is designed to catch large debris. It allows all flood flows to pass through the debris poles. It is assumed that the largest river flow will be below the maximum height of the poles and will span the length of the debris catchment structure. The structure consists of a 2-foot thick concrete pad that spans 140 feet across the stream and the floodplain with a width of 8 feet. Steel posts 8 inches in diameter and between 4 to 7 feet high are evenly spaced at 4 feet along the center of the concrete pad (*Oceanit, 2008c*).

Poelua Place Debris Basin

This basin is designed to provide a capture point for large debris before they reach bridges downstream. In addition, the debris basin will slow the velocity of floodwaters. The debris basin is intended to capture debris in flows larger than a 50-percent ACE (2-year) stream flow and allow passage of all flows.

The debris basin consists of two separate structures. On the east side is the actual basin. The old oxbow lot will be dug down to reclaim the bend in the stream. A small berm surrounding the basin protects the existing neighborhoods from any water that may spill out of the basin. Water carrying large debris enters the northern end of the basin, curves around, and reenters the stream at the south end. Any large debris floating atop the flood waters are caught by a debris catcher consisting of five 8 inch diameter steel posts secured by a concrete pad.

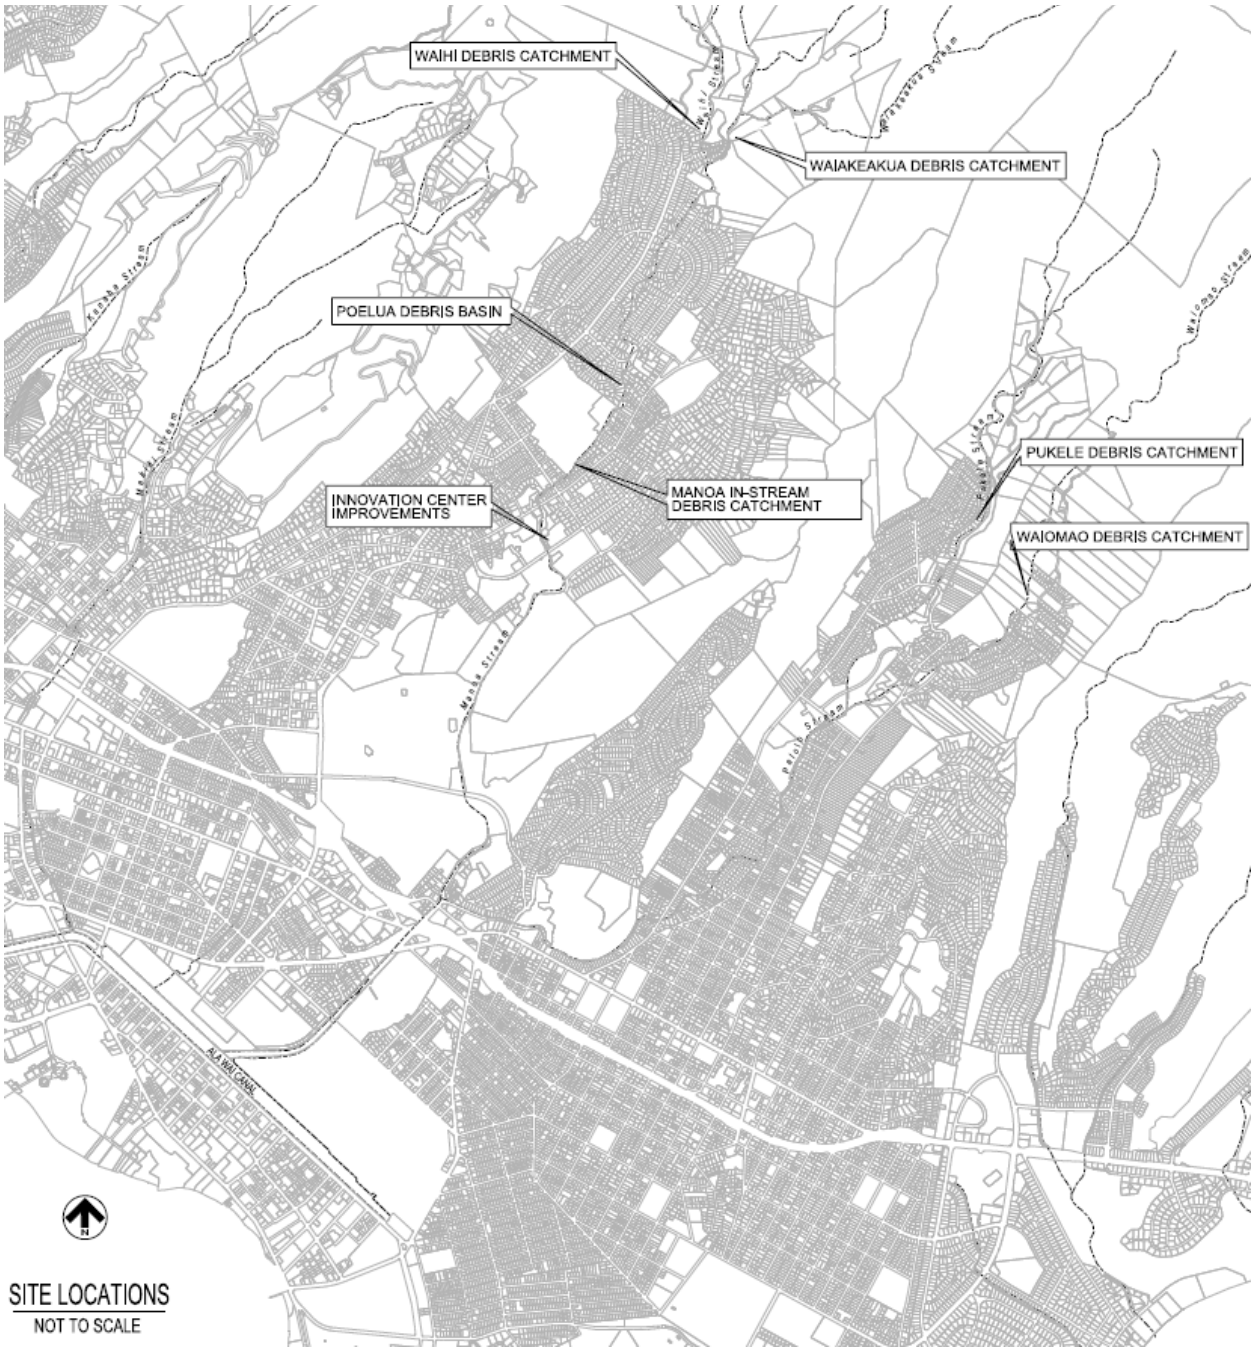

Figure 11: Preliminary Debris Catchment Locations

Manoa In-Stream Debris Catchment

This structure is designed to catch large debris. It allows all flood flows to pass through the debris poles. It is assumed that the largest river flow will be below the maximum height of the poles and will span the length of the debris catchment structure. The structure consists of a 2-foot thick concrete pad that spans 60 feet across the stream

and the floodplain with a width of 8 feet. Steel posts 8 inches in diameter and between 4 to 7 feet high are evenly spaced at 4 feet along the center of the concrete pad.

Innovation Center Improvements

The basis of this design is to restore the original floodplain between East Manoa Road Bridge and Woodlawn Bridge to lower the volume of floodwaters entering downstream of Woodlawn Bridge. A new floodplain will be created. The floodplain is intended to be inundated and capture debris when flows exceed the 50-percent ACE (2-year) storm flow. Water on the floodplain will re-enter the stream after is passes through the debris catchers (*Oceanit, 2008c*). The debris catchers consists of a 1-foot thick concrete pad that spans 250 feet parallel to the stream and the floodplain with a width of 6 feet. Steel posts 8 inches in diameter and 4 feet high are evenly spaced at 6 feet along the center of the concrete pad.

Waiomao Debris Catchment

This structure is designed to catch large debris. It allows all flood flows to pass through the debris poles. It is assumed that the largest river flow will be below the maximum height of the poles and will span the length of the debris catchment structure. The structure consists of a 2-foot thick concrete pad that spans 50 feet across the stream and the floodplain with a width of 8 feet. Steel posts 8 inches in diameter and between 4 to 7 feet high are evenly spaced at 4 feet along the center of the concrete pad.

Pukele Debris Catchment

This structure is designed to catch large debris. It allows all flood flows to pass through the debris poles. It is assumed that the largest river flow will be below the maximum height of the poles and will span the length of the debris catchment structure. The structure consists of a 2-foot thick concrete pad that spans 25 feet across the stream and the floodplain with a width of 8 feet. Steel posts 8 inches in diameter and between 4 to 7 feet high are evenly spaced at 4 feet along the center of the concrete pad.

6.3 Floodwall AnalysisIn order to determine the effectiveness of floodwalls throughout the watershed, the HEC-RAS model, the Technical Summary Report, Manoa Watershed Project (*Oceanit, 2008c*), and other analysis were used to study different floodwall scenarios.

6.3.1 Preliminary Analysis

Initially, 3 different sites were selected throughout the watershed. **Figure 12** shows the locations of the proposed floodwall sites. Each floodwall system was designed to maximize effectiveness while remaining in a viable location within reasonable vertical and horizontal limitations.

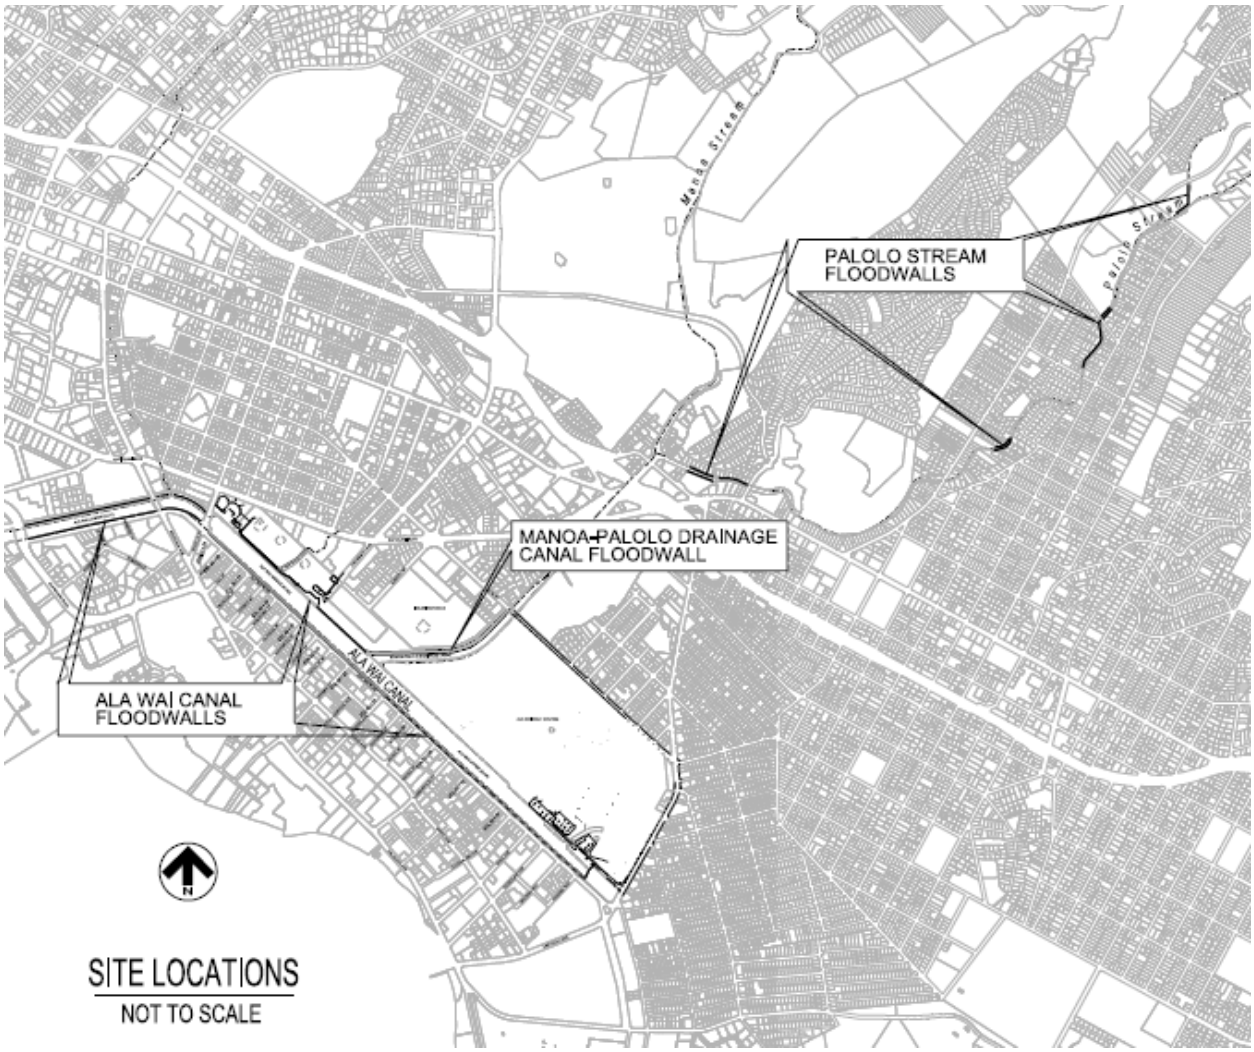

Figure 12: Preliminary Floodwall Locations

Palolo Stream Floodwalls

The Palolo Stream Floodwall system is designed to keep the 1-percent ACE (100-year) flow within the existing concrete stream channel with 90% Assurance. The floodwalls will be constructed out of reinforced concrete.

Manoa-Palolo Drainage Canal Floodwall

The Manoa-Palolo Drainage Canal Floodwall system is designed to keep the 1-percent ACE (100-year) flow from flooding the right bank with 90% Assurance. The floodwall will be constructed out of reinforced concrete and will run along the right bank from Date Street to the Ala Wai Canal.

Ala Wai Canal Floodwalls

The Ala Wai Canal Floodwall system is designed to keep the 1-percent ACE (100-year) flow within the existing channel with 90% Assurance. The entire floodwall system will be constructed out of reinforced concrete. At the upstream end the floodwall system will connect to the Ala Wai Golf Course Levee and run along the left bank of the Ala Wai Canal. There will be no floodwall on the right bank of the Canal next to the golf course. The floodwall system will continue to run along both banks all the way to the Ala Moana Blvd Bridge.

7 ALTERNATIVES

After doing analysis on the different detention basins combined with other measures such as debris catchments and floodwalls alternatives were developed. See the Feasibility Report for the full formulation of the Alternatives. This section explains which measures were used for three different alternatives.

7.1 Alternative 1A

Alternative 1A was developed using the Manoa Dam to detain as much flow as it could without using other detention measures along Manoa Stream. The emphasis of this alternative was the Manoa Dam because majority of the flows that reach the Ala Wai Canal are from Manoa Stream. The Manoa Dam would be constructed to allow debris to be caught during storm events to prevent debris from the upper watershed from entering Manoa Stream. An in-stream debris catchment was also used in this alternative to catch debris that entered the stream downstream of the dam. This measure is located right below Manoa District Park.

Waiomao Debris and Detention Basin and Pukele Debris and Detention Basins were also used in this alternative above Palolo Stream. These two measures were used to lower the peak flow in Palolo Stream, these measures also prevented debris from entering the concrete lined Palolo Stream. The two debris and detention basins did not lower the 1-percent ACE (100-year) storm enough to provide 90% Assurance so floodwalls were also added to this alternative in certain areas to attain 90% Assurance for the 1-percent ACE (100-year) event. A floodwall was also added on the right bank of the Manoa-Palolo Drainage Canal to prevent flooding in and around Iolani School.

The Roosevelt Debris and Detention Basin was used in the Makiki Watershed to lower the peak flow. This measure also catches debris to prevent it from entering Makiki Stream. Floodwalls were analyzed in Makiki but they were not feasible because of the required heights.

Even with the Manoa Dam, floodwalls along the Ala Wai Canal are still needed to prevent the 1-percent ACE (100-year) storm event from flooding Waikiki and Moiliili. The Hausten Ditch Detention was used in conjunction with the Ala Wai Canal Floodwall system to prevent interior drainage from flooding Moiliili when slide gates are closed at the Hausten Ditch Pedestrian Bridge.

7.2 Alternative 2A

The emphasis for Alternative 2A was not to detain water in the un-urbanized areas. Therefore, there were no detention basins or dams in the upstream areas of Manoa Stream but the Woodlawn Ditch Detention Basin, the Manoa Park Detention Basin, and the Kanewai Field Multi-Purpose Detention Basin were used in this alternative. Because there were no debris and detention basins in the upstream area a debris catchment will be constructed at Waiakeakua Stream and Waihi Stream. An in-stream debris catchment will also be constructed at Poelua Place; this is just upstream of the Manoa Park Detention Basin's intake so the debris catchment prevents debris from going down stream of that location including preventing debris from clogging up the intake. An in-stream debris catchment will also be constructed next to the Innovation Center just upstream of Woodlawn Bridge.

No detention measures were used in the Palolo Watershed; there just isn't any land available along Palolo Stream. The floodwall from Alternative 1 was also added on the right bank of the Manoa-Palolo Drainage Canal to prevent flooding in and around Iolani School.

The Makiki Debris and Detention Basin and the Roosevelt Debris and Detention Basins were used in the Makiki Watershed because that was the only measure that could be used to lower flows in that watershed. Same as Alternative 1, the floodwalls were analyzed in Makiki but they were not feasible because of the required heights.

Floodwalls along the Ala Wai Canal are also needed to prevent the 1-percent ACE (100-year) storm event from flooding Waikiki and Moiliili. The Hausten Ditch Detention was used in conjunction with the Ala Wai Canal Floodwall system to prevent interior drainage from flooding Moiliili when slide gates are closed at the Hausten Ditch Pedestrian Bridge. The Ala Wai Golf Course Multi-Purpose Detention was also used in conjunction with the Ala Wai Canal Floodwall system.

7.3 Alternative 3A

This alternative was created to lower as much flow as possible without using the Manoa Dam, a more effective and logical approach to flood protection. The Waiakeakua Debris and Detention Basin along with the Waihi Debris and Detention Basin and the Woodlawn Ditch Detention Basin were used along Manoa Stream. The in-stream debris catchment below Manoa District Park would also be a part of this alternative to catch debris that enters the stream downstream of Waiakeakua and Waihi Streams. The debris catchment at the Innovation Center was initially part of this alternative but after doing incremental justification the Kanewai Field Multi-Purpose Detention Basin was a better overall measure to use in this alternative instead.

The Waiomao Debris and Detention Basin and the Pukele Debris and Detention Basin were both used for the Palolo Watershed. After doing further analysis the floodwalls along Palolo Stream were too costly and infeasible. Further analysis was also done on

the floodwall along the Manoa-Palolo Drainage Canal and that measure was not incrementally justified.

The Makiki Watershed initially used the Makiki Debris and Detention Basin and the Roosevelt Debris and Detention Basins but after incremental justification the Roosevelt Debris and Detention Basin was not justified. As in Alternatives 1 and 2, the floodwalls were analyzed in Makiki but they were not feasible because of the required heights.

Floodwalls along the Ala Wai Canal are also needed in this alternative to prevent the 1-percent ACE (100-year) storm event from flooding Waikiki and Moiliili. The Hausten Ditch Detention was used in conjunction with the Ala Wai Canal Floodwall system to prevent interior drainage from flooding Moiliili when slide gates are closed at the Hausten Ditch Pedestrian Bridge. The Ala Wai Golf Course Multi-Purpose Detention was also used in conjunction with the Ala Wai Canal Floodwall system. This alternative became our TSP.

Detailed hydrologic modeling of the detention basins included as part of the TSP was performed to refine the design and determine their effectiveness as part of the system-wide alternative. The detention basins were inserted into the HEC-HMS hydrologic model and simulation runs were made for the 50%, 20%, 10%, 5%, 2%, 1%, 0.5%, and 0.2% AEP events. In addition, a 0.999% AEP event simulation was run for purposes of inclusion into the HEC-FDA economic model. Figure 13 below shows the HEC-HMS basin schematic for Alternative 3A.

For each detention basin, elevation-storage relationships were developed in GIS from the elevation data. Initial outlet configurations were selected and the hydrologic model was run to determine the basin effectiveness. The initial objective of the basin design was to allow flows up to the 20% AEP event to pass with minimal storage and to reduce outflows at the 1% AEP event to be sufficiently reduced to provide flood damage reduction benefits. Through an iterative process, embankment elevations and outlet configurations were adjusted until satisfactory results were obtained. The final basin specifications and modeling results are presented in the following section.

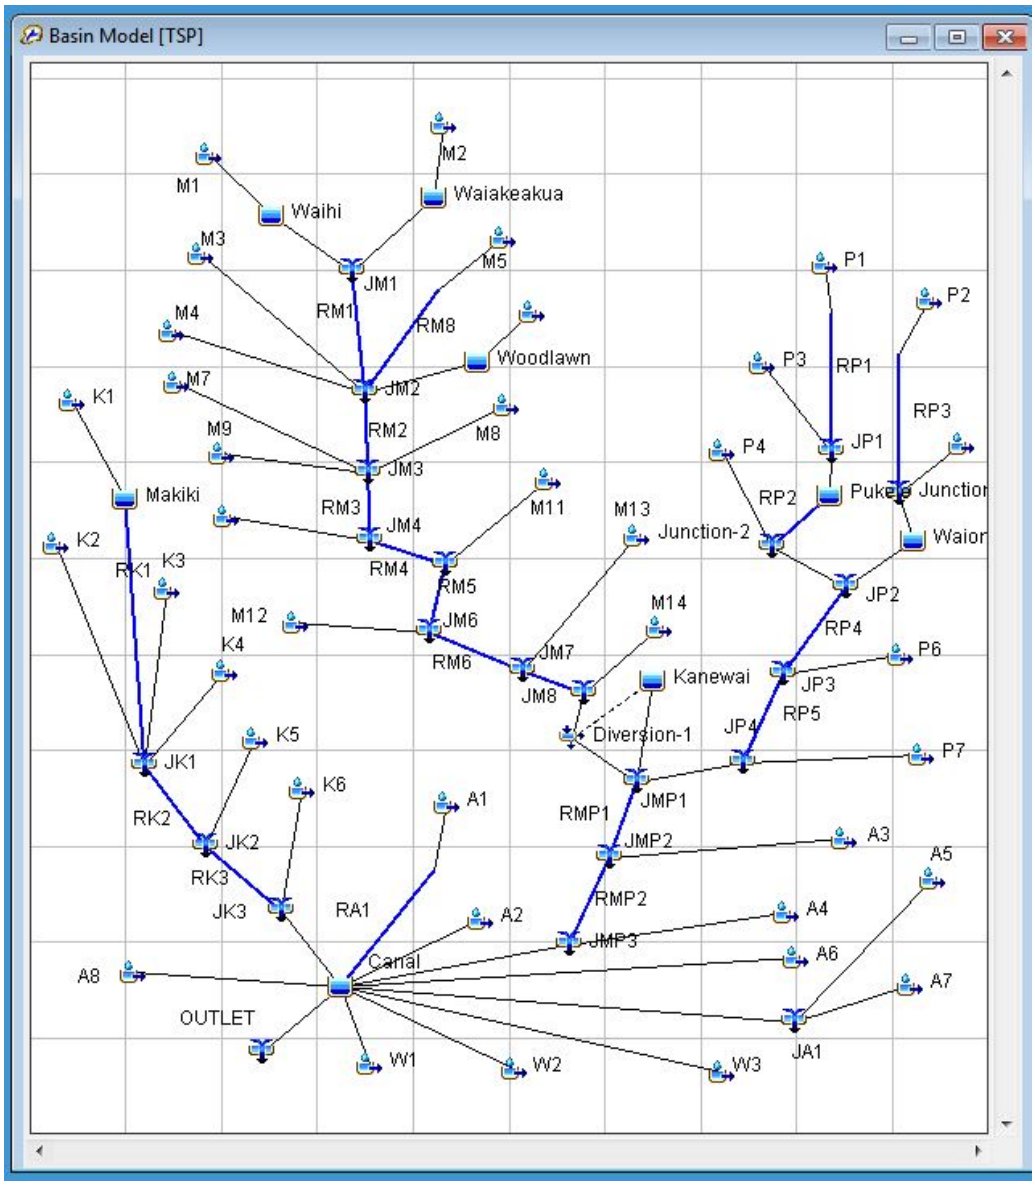

Figure 13. HEC-HMS Basin Schematic – Alternative 3A

7.3.1 Detention Analysis

As a result of the hydrologic modeling, refinements to the basin specifications were made which differ from the preliminary analysis. The refined basin specifications are described in the following paragraphs.

Waiakaekua Detention and Debris Basin

The detention basin will be formed by constructing an earthen berm approximately 34 feet in height and having a 20 foot top width. The top of the berm will be set at elevation 338.0 ft msl. A 1 foot thick concrete spillway 40 feet in length and 80 feet in width will

be constructed at elevation 334.0 ft msl. The downstream face of the embankment will have a slope of 2H:1V and the upstream face will have a slope of 3H:1V. A 2 foot thick layer of grouted riprap will protect the embankment face from erosion.

The outlet of the basin will consist of a 12' x 6' corrugated metal arch. The ends of the arch will be mitered to match the embankment slopes. The estimated length of this culvert is about 200 feet. The upstream invert of the culvert is at elevation 304.0 ft msl and the downstream invert is at elevation 299.0 ft msl. At the upstream end of the outlet culvert, a series of seven (7) eight inch diameter concrete filled steel pipe will be installed to serve as a debris trap. The downstream end of the outlet culvert will require riprap protection from erosion.

This basin configuration was modeled in the hydrologic model and the following table, **Table 10**, shows the results of the modeling.

Table 10. Waiakaekua Detention Basin Modeling Results

Exceedance Prob. (%)	Recurrence Interval	HEC-HMS Output			
		Inflow (cfs)	Outflow (cfs)	Storage (ac-ft)	Elev. (ft)
0.999	1	331	331	0.3	309.2
50	2	514	512	0.9	311.2
20	5	813	758	4.2	317
10	10	1075	930	9	321.2

2	50	1786	1272	33.1	332.1
1	100	2128	1643	43.9	335.1
0.5	200	2503	2167	47.9	336.2
0.2	500	3034	2834	51.6	337.2

Woodlawn Ditch Detention Basin

The detention basin will be formed by constructing an earthen berm approximately 20 feet in height and having a 10 foot top width. The top of the berm will be set at elevation 220.0 ft msl. A 1 foot thick concrete spillway 25 feet in length and 80 feet in width will be constructed at elevation 217.0 ft msl. The downstream face of the embankment will have a slope of 2H:1V and the upstream face will have a slope of 3H:1V. A 2 foot thick layer of grouted riprap will protect the embankment face from erosion.

The outlet of the basin will consist of a 12' x 4.1' corrugated metal arch culvert. The ends of the arch will be mitered to match the embankment slopes. The estimated length of this culvert is about 110 feet. The upstream invert of the culvert is at elevation 200.0 ft msl and the downstream invert is at elevation 199.0 ft msl.

This basin configuration was modeled in the hydrologic model and the following T**able 11** shows the results of the modeling.

Table 11. Woodlawn Ditch Detention Basin Modeling Results

Exceedance Prob. (%)	Recurrence Interval	HEC-HMS Output			
		Inflow (cfs)	Outflow (cfs)	Storage (ac-ft)	Elev. (ft)
0.999	1	122	119	0.7	205.3
50	2	190	184	1.2	207.1
20	5	300	282	2.1	209.5
10	10	394	364	3.1	211.5

2	50	646	554	7.1	216.4
1	100	765	710	8.6	217.6
0.5	200	896	866	9.1	218.1
0.2	500	1079	1068	9.8	218.5

Kanewai Field Detention Basin

The detention basin will be formed by constructing an earthen berm approximately 9 feet in height and having a 10 foot top width. The top of the berm will be set at elevation 43.0 ft msl. Flow will enter the basin by way of a lateral weir located at the northwest corner of the basin along the left bank of Manoa Stream. The weir will consist of a 2 foot thick concrete spillway set at elevation 40.0 ft msl and having a weir length of 54 feet. The weir will have side slopes of 3H:1V until meeting the berm elevation for a total length of 60 feet. The interior face of the embankment will have a slope of 2H:1V and the exterior face will have a slope of 3H:1V. A 2 foot thick layer of grouted riprap will protect the spillway approach slopes from erosion.

The outlet of the basin consists of an existing 2' diameter drainage pipe leading back into Manoa Stream. The inlet of the drainage pipe is set at the floor of the basin at its existing elevation of 34.0 ft msl. The outlet of the pipe extends into the left bank of the stream.

This basin configuration was modeled in the hydrologic model and the following **Table 12** shows the results of the modeling.

Table 12. Kanewai Detention Basin Modeling Results

Exceedance Prob. (%)	Recurrence Interval	HEC-HMS Output			
		Inflow (cfs)	Outflow (cfs)	Storage (ac-ft)	Elev. (ft)
0.999	1	0	0	0	30
50	2	0	0	0	30

1	100	504	42.2	27.2	41
0.5	200	553	42.2	27.4	41.1
0.2	500	746	42.3	27.7	41.1

Waihi Detention and Debris Basin

The detention basin will be formed by constructing an earthen berm approximately 37 feet in height and having a 10 foot top width. The top of the berm will be set at elevation 404.0 ft msl. A 1 foot thick concrete spillway 20 feet in length and 100 feet in width will be constructed at elevation 400.0 ft msl. The downstream face of the embankment will have a slope of 2H:1V and the upstream face will have a slope of 3H:1V. A 2 foot thick layer of grouted riprap will protect the embankment face from erosion.

The outlet of the basin will consist of a 12' x 6' box culvert with wingwalls flared at an angle of 45 degrees and extending until they reach the natural channel side slope. The estimated length of this culvert is about 205 feet. The upstream invert of the culvert is at elevation 367.0 ft msl and the downstream invert is at elevation 357.0 ft msl. At the upstream end of the outlet culvert, a series of seven (7) eight inch diameter concrete filled steel pipe will be installed to serve as a debris trap. The downstream end of the outlet culvert will require riprap protection from erosion.

This basin configuration was modeled in the hydrologic model and the following **Table 13** shows the results of the modeling.

Table 13. Waihi Detention Basin Modeling Results

Exceedance Prob. (%)	Recurrence Interval	HEC-HMS Output			
		Inflow (cfs)	Outflow (cfs)	Storage (ac-ft)	Elev. (ft)
0.999	1	488	486	0.2	373.5
50	2	756	755	0.4	375.9
20	5	1199	1174	1.5	381.2

1	100	3102	2919	19.8	401.9
0.5	200	3640	3581	21.3	402.8
0.2	500	4400	4332	23	403.7

Waiamao Detention and Debris Basin

The detention basin will be formed by constructing an earthen berm approximately 33.5 feet in height and having a 10 foot top width. The top of the berm will be set at elevation 402.0 ft msl. A 1 foot thick concrete spillway 20 feet in length and 100 feet in width will be constructed at elevation 398.6 ft msl. The downstream face of the embankment will have a slope of 2H:1V and the upstream face will have a slope of 3H:1V. A 2 foot thick layer of grouted riprap will protect the embankment face from erosion.

In order to obtain the required storage, excavation of the channel bottom is required. This excavation will enlarge the channel to a 30 foot bottom width having near vertical side slopes (0.5:1HV). From the upstream invert of the outlet culvert the channel bottom will rise at a slope of 2% for a distance of about 200 feet to aid in draining the basin. At this point the channel will transition to the existing channel geometry over a distance of about 200 feet. This excavation will remove an estimated 3.060 CY of material.

The outlet of the basin will consist of a 20’ x 5’ box culvert with a headwall extending across the channel bottom. The estimated length of this culvert is about 178 feet. The upstream invert of the culvert is at elevation 368.6 ft msl and the downstream invert is at elevation 367.6 ft msl. At the upstream end of the outlet culvert, a series of seven (7) eight inch diameter concrete filled steel pipe will be installed to serve as a debris trap. The downstream end of the outlet culvert will require riprap protection from erosion.

This basin configuration was modeled in the hydrologic model and the following **Table 14** shows the results of the modeling.

Table 14. Waiamao Detention Basin Modeling Results

Exceedance Prob. (%)	Recurrence Interval	HEC-HMS Output			
		Inflow (cfs)	Outflow (cfs)	Storage (ac-ft)	Elev. (ft)

0.5	200	3873	2636	48.9	397
0.2	500	4707	3162	77.7	399.8

Pukele Detention and Debris Basin

The detention basin will be formed by constructing an earthen berm approximately 30 feet in height and having a 10 foot top width. The top of the berm will be set at elevation 441.0 ft msl. A 1 foot thick concrete spillway 20 feet in length and 80 feet in width will be constructed at elevation 437.0 ft msl. The downstream face of the embankment will have a slope of 2H:1V and the upstream face will have a slope of 3H:1V. A 2 foot thick layer of grouted riprap will protect the embankment face from erosion.

In order to obtain the required storage, excavation of the channel bottom is required. This excavation will enlarge the channel to a 30 foot bottom width having near vertical side slopes (0.5:1HV). From the upstream invert of the outlet culvert the channel bottom will rise at a slope of 1% for a distance of about 200 feet to aid in draining the basin. At this point the channel will transition to the existing channel geometry over a distance of about 300 feet. This excavation will remove an estimated 14,330 CY of material.

The outlet of the basin will consist of a 120’ x 6’ box culvert with a headwall extending across the channel bottom. The estimated length of this culvert is about 160 feet. The upstream invert of the culvert is at elevation 407.0 ft msl and the downstream invert is at elevation 405.0 ft msl. At the upstream end of the outlet culvert, a series of seven (7) eight inch diameter concrete filled steel pipe will be installed to serve as a debris trap. The downstream end of the outlet culvert will require riprap protection from erosion.

This basin configuration was modeled in the hydrologic model and the following **Table 15** shows the results of the modeling.

Table 15. Pukele Detention Basin Modeling Results

Exceedance Prob. (%)	Recurrence Interval	HEC-HMS Output			
		Inflow (cfs)	Outflow (cfs)	Storage (ac-ft)	Elev. (ft)
0.999	1	158	154	0.7	409.8

0.2	500	3778	3612	39.4	440.5

Makiki Detention and Debris Basin

The detention basin will be formed by constructing an earthen berm approximately 33.2 feet in height and having a 10 foot top width. The top of the berm will be set at elevation 184.0 ft msl. A 1 foot thick concrete spillway 20 feet in length and 60 feet in width will be constructed at elevation 180.8 ft msl. The downstream face of the embankment will have a slope of 2H:1V and the upstream face will have a slope of 3H:1V. A 2 foot thick layer of grouted riprap will protect the embankment face from erosion.

In order to obtain the required storage, excavation of the channel bottom is required. This excavation will enlarge the channel to a 30 foot bottom width having near vertical side slopes (0.5:1HV). From the upstream invert of the outlet culvert the channel bottom will rise at a slope of 2% for a distance of about 280 feet to aid in draining the basin. At this point the channel will transition to the existing channel geometry over a distance of about 200 feet. This excavation will remove an estimated 3.035 CY of material.

The outlet of the basin will consist of a 120’ x 6’ box culvert with a headwall extending across the channel bottom. The estimated length of this culvert is about 160 feet. The upstream invert of the culvert is at elevation 407.0 ft msl and the downstream invert is at elevation 405.0 ft msl. At the upstream end of the outlet culvert, a series of seven (7) eight inch diameter concrete filled steel pipe will be installed to serve as a debris trap. The downstream end of the outlet culvert will require riprap protection from erosion.

This basin configuration was modeled in the hydrologic model and the following **Table 16** shows the results of the modeling.

Table 16. Makiki Detention Basin Modeling Results

Exceedance Prob. (%)	Recurrence Interval	HEC-HMS Output

7.3.2 Peak Flow Data

The results of the hydrologic modeling were tabulated and served as the input for the hydraulic model for improved conditions. Table 15 below shows the peak flows for Alternative 3A, the Tentatively Selected Plan (TSP). Flows for the Golf Course Detention basin, the Kanewai Detention basin, Kanaha Split reach, and the UH_split reach were indexed by 0.01 cfs due to the requirement in HEC-FDA that flows are constantly increasing within a cross section. **Tables 17** and **18** compares the peak flows from the existing without-project condition with the with-project Alternative 3A condition

7.3.3 Uncertainty and EYOR

The uncertainty of the peak flow discharge values is based on the equivalent years of record. The final equivalent years of record (EYOR), used in the risk and uncertainty of the HEC-FDA model is based on stream reach and is presented in Table 17. The Makiki Watershed with the least amount of available data was given the lowest EYOR of 18 years, while the remaining sub-watersheds were assigned values from 25 to 30 years. The highest values were from sub-basins where the peak flow discharges were almost entirely based on gaged data; Pukele and Waiomao Streams. The assigned EYOR is based on the overall confidence in the reliability or accuracy of the peak flow discharge estimates and as applied in HEC-FDA constrains the confidence limits of the sampling

of peak flow discharge estimates. The initial values in **Table 19** were determined from the final output discharge values from HEC-RAS and methodology in Bulletin 17B, Appendix 5 (Interagency Advisory Committee on Water Data, 1982). The actual usage of these values versus the graphical curve method is discussed in the Economic Appendix.

EYOR = Equivalent Years of Record; ----, not a separate sub-basin in HEC-HMS model

7.3.4 Scour and Erosion Protection

At each of the 5 primary in-stream detention basins, Makiki, Waihi, Waiakeakua, Pukele, and Waiamao, exit velocities ranged from 27 to 35 ft/s for the 1% ACE flood event. Natural stream velocities at these locations without any project features ranged from 18 to 24 ft/s for the 1% ACE flood event. Due to the increased velocities and concentrated flow at the culvert outlets, a dissipation and scour protection basin was designed and added to each of the primary in-stream detention basins. Given the similar hydraulic characteristics at each location, the 1% ACE flood event highest velocity of 35.4 ft/s at the Waihi Stream detention basin was used as the input design parameters to provide a constant set of output design parameters to be used at all five detention basins. Other design input parameters included 12 ft by 6 ft box culvert with 4.88% slope, manning's n of 0.015, tailwater depth of 4.4 ft and outlet depth in culvert of 4.9 ft.

Guidance in the Federal Highway Administration (FHWA) report FHWA-NHI-06-086, Hydraulic Design of Energy Dissipators for Culverts and Channels, Hydraulic Engineering Circular Number 14, Third edition was used to design the rip rap dissipation and scour protection basins. This report provides design procedures based on research and field survey of practices and experience. For this particular design, the rip rap basin typical in **Figure 14** was used.

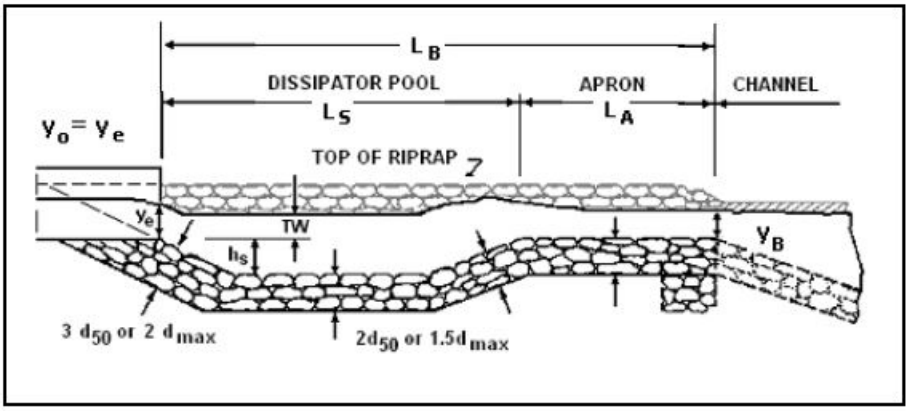

Figure 14. Typical Profile of Rip Rap Basin (Figure 10.1 in FHWA HEC-14)

Using VDOT Class Ill riprap (D_{50} = 2.2 ft) the riprap basin would have the following dimensions:

- Length of dissipation pool (Ls) = 86 ft
- Dissipator pool depth {h_s} = 8.6 ft
- Length of apron (L_A) = 43 ft
- Total basin length (L_s)= 129 ft

- Basin width at the basin exit {W_s} = 98 ft ideal, but varies by stream width at each location
- Basin side slope (z) = 2H:1V
- Riprap Basin exit velocity {V_e)= 9.5 ft/sec

The basin width at the end of the apron was 50 ft at the Makiki basin, 90 ft at the Waihi basin, 70 ft at the Waiakeakua basin, 60 ft at the Pukele basin, and 60 ft at the Waiamao basin. The design typical is illustrated in Plate 11 on sheet C-308.

7.4 WITH PROJECT HYDRAULIC MODELING

Peak flows developed from the With Project hydrologic model were used to determine water surface elevations for the TSP.

The hydraulic model geometry was modified to include the upstream detention and debris basins, floodwalls, and the Ala Wai Golf course Detention basin. In Section 3.1.4, there is a discussion on blockages of several bridge structures due to debris. Since the upstream detention basins contain mechanisms to trap debris, these blockages were removed from the model geometry.

The Ala Wai Golf Course Detention basin is an off-channel basin which accepts water which overfows the main channel. Water enters the basin from the upper reach of the Ala Wai canal and the left bank of the Manoa-Palolo canal below the Date St. Bridge. These overflows are modeled as lateral weirs. On the Ala Wai canal, the right bank serves as the weir. Overflow occurs from its confluence with the Manoa-Palolo canal up stream to its end. The weir coefficient was set to be 0.3. On the Manoa-Palolo canal, water overtops the left bank and enters the golf course detention. This weir coefficient was set to be 1.0. The golf course detention area was modeled as a separate reach in order to route flows thru the basin.

7.4.1 Model Results

On the Ala Wai canal, results of the modeling show that flow begins to enter the golf course detention from the Ala Wai side at the 50% AEP event thru a low point along the bank profile. Along the Manoa-Palolo stream, flow will begin overtopping the left bank at the 20% AEP event. At the 1% AEP event, a total of 4940 cfs is diverted to the golf course and the detention area has an elevation of about 5.3 msl.

The floodwalls along the Ala Wai canal protect Waikiki and the surrounding area from flood damage. On the left bank of the canal, the floodwalls begin at the Ala Moana Blvd. bridge and extend upstream to the end of the canal, where it joins the earthen levee that forms the golf course detention basin. On the right bank of the canal, the floodwall also begins at the Ala Moana Blvd. Bridge, but is not continuous. The floodwall breaks at the confluence with Makiki Stream. It then begins again above Makiki Stream and upstream to the confluence with the Manoa-Palolo canal. This break, at Makiki Stream, allows water to back up into the stream and prevent the stream

from draining. The economic analysis will determine the effect this has on the area surrounding Makiki Stream.

Initial elevations of the floodwalls were set to be 2 feet above the 1% AEP water surface elevation. A risk analysis was performed to determine the final levee heights that will satisfy a conditional non-exceedance probability (CNP) of at least 90%. The results of the analysis show that for reach ALA1, the floodwall elevation at the index point (sta. 1477) is 6.3. For reach ALA2, the floodwall elevation at the index point (sta. 4847) is 8.75, and for reach ALA3A, at the index point (sta. 8015) is 9.3. **Table 20** shows the average elevation and height of the floodwalls by reach. Further discussion of the analysis is presented in the Economic Appendix. **Plate 2** shows cross sections plots at the index points of the modeled streams for the TSP.

Table 20. Average Elevations and Heights of Ala Wai Canal Floodwalls in Feet

REACH	Left Bank		Right Bank	
	Ave. Elev.	Ave. Height	Ave. Elev.	Ave. Height
ALA1	5.7	1.1	5.7	1
ALA2	8.5	3.3	8.5	3.4
ALA3	9.3	4.4	NA	NA

There is a concern that installation of the floodwalls will have an adverse impact on the three bridges crossing the Ala Wai Canal. Water surface elevations at or higher than the low chord elevations of the bridges may cause undue uplift pressure on the bridge structure and would require some measure of strengthening to mitigate. The results of the model show that the maximum water surface elevations do not impinge on the maximum low chord of the bridges. **Table 21** below show the comparison of with project water surface elevations with the bridge deck and low chord elevations.

Table 21. Comparison of Bridge Data with Water Surface Elevations for With Project Conditions

Bridge	Top of Roadway at highest low chord (ft)	Highest Low Chord (ft)	Station on Sheet C-310	Left Bank Elevation at sta. (ft)	Top of Floodwall Elevation at sta. (ft)	1% AEP WSE (ft)	0.5% AEP WSE (ft)	0.2% AEP WSE (ft)
Ala Moana Blvd	11.60	7.40	4+39	5.00	5.00	2.55	2.56	2.57
Kalakaua Ave	8.80	6.6	23+24	5.9	7.3	5.57	5.58	5.59
McCully St.	10	8.81	31+06	5.5	7.6	6.57	6.77	6.97
WSE = water surface elevation								

At the Manoa-Palolo canal, water overtops the right bank and will inundate the area around the Iolani School. An economic analysis was performed to determine whether extending the floodwall upstream to the Date St. Bridge can be incrementally justified. This analysis showed the floodwall extension to be economically infeasible.

At several locations along the streams modeled, hydraulic jumps appear. These jumps occur at the upstream side of various bridges and culverts and are mainly a result of changes in topography and channel slope as the stream bed transitions from the steep uphill areas to the flatter valley areas.

In general, implementation of the recommended plan reduces peak flows entering the Ala Wai Canal system and the floodwalls protect the surrounding area from damage due to flooding. Plate 4 shows the water surface profiles of the modeled stream for the TSP.

8 INTERIOR DRAINAGE

Along both banks of the Ala Wai canal, there are numerous drainage outlets from the storm sewer system. These outlets will require the installation of flap-gates to prevent water from backing up and inundating areas beyond the floodwalls. During storm events, these flap-gates will close and prevent water from draining into the canal. This will cause residual flood inundation to the areas protected by the floodwalls. This residual flooding is not expected to be significant due to it being shallow sheetflow and not dep ponding.

To determine impacts of storm drain or storm sewer outfalls being shut during periods of high water surface elevation in the Ala Wai Canal with the project floodwalls, stormdrains greater than 18-inch diameter pipes along the Ala Wai Canal (21 out of 43 outfalls) were analyzed for backwater impacts. Only the larger stormdrain pipe or culvert sizes were chosen for this analysis since these stormdrains had drainage areas larger than 4 acres and pipe sizes greater than 18-inches. Many of the small outfalls only drain the Ala Wai Boulevard roadway, those of single 18-inch or less diameter pipes (22 out of 43 outfalls), have very minimal drainage areas, will only have minor impacts to Ala Wai Boulevard in case of backwater, and would have only minor residual damages if any.

To evaluate the interior flooding due to backwater in gravity storm drains, the coincident frequency assumption is that the interior flooding input for these gravity outlets to the canal would use the 10% 1-hour rainfall intensity volumes and given the flashy nature of runoff in the watershed, the gates could be closed for up to 6 hours depending on the riverine flood event. Next the pipe and channel storage; i.e. volume capacity; for those stormdrain outfalls were determined based on the pipe or culvert sizes and lengths. Then using existing topographic data to determine the street elevation of stormwater inflow grates and overbank conditions, excess volumes which exceeded the storm drain capacities were mapped assuming that the shallow flooding, up to 1 foot depth, would spread following the local topology with roads serving as the primary channels of this

excess backwater flow. Figure 15 illustrates the shallow flooding areas, based on 1 foot depth, for the storm drains analyzed.

As part of this interior drainage analysis, similar analyses were done at each of the pump station locations assuming the pump station did not exist or was not functioning. For these locations, the excess volume was much greater than for the other stormdrains due to larger drainage areas. Additionally for the economic justification of each pump station, multiple storm events were analyzed to determine frequency-stage curves for each impacted area. For the pump stations, the flooded area was determined using the TIN/Lidar data in ArcGIS to help determine the depth/area/duration of interior flooding which would be converted to economic damages.

For Pump Station 1, located at the east end of the Ala Wai Canal, the large drainage area of 290 acres generates an excess volume of 31 acre-feet for the 10% ACE storm event. This excess volume would first flood Kapahulu Avenue and it was assumed that the flooding would follow the streets first before spreading out. The potential inundation area would flood the Ala Wai library and Thomas Jefferson Elementary school grounds before moving south to the Kapahulu Avenue stormdrain, where it is assumed that this 10 ft by 5 ft box could help convey this water out to ocean and the remaining floodwaters would continue to move down Kapahulu Avenue towards the ocean. There are low areas towards Kapiolani Park, if floodwaters cross Kapahulu Avenue and enter the park, the park space could hold all 31 acre-ft. The area represented as Pump Station 1 and 2 Flood Area in Figure 15 represents an area of 115 acres, which is sufficient to even hold the 0.2% ACE interior flood volume of 80 acre-feet at less than 1 foot depth. This area represents the Honolulu Zoo area of Kapiolani Park and does not spread out across the park. It is assumed the drainage ditch in the park and the stormdrains along Monserrat Avenue with catch and divert the shallow flooding before it can spread to the entire park. The worst case is shown in Figure 15 as Pump Station 1 and 2 Maximum Flooding Area, which does include the entire park. That would be improbable as the 0.2% ACE interior storm events for both Pump Stations 1 and 2 generate an excess volume of 125 acre-feet, which would not be able to cover the entire 200 acres represented by that area. For Pump Station 2, the excess water would be about 3 feet deep at the base of the golf course levee and less than a foot deep over Kapahulu Avenue at Herbert Street. The potential floodwaters would run south along Kapahulu Avenue down to Ala Wai Boulevard, where it would presumably pond in the low area by the library or continue to travel down Kapahulu Avenue and also potentially enter the park area as described above, although the excess volume for this location of 19 acre-feet is much less that that from Pump Station 1.

Pump station 3 is located by University Avenue and drains an area of 125 acres. Excess volume for the 10% ACE storm event is about 12 acre-feet. Flooding would begin on Hihiwai Street and there would be 1 foot deep flooding at the Ala Wai Elementary School, community gardens, and possibly also onto the campus of Iolani School and nearby apartment and residential buildings (Figure 15). As discussed for Pump Satations1 and 2 previously, a frequency-stage curve was computed for this pump station flooded area as well for the economic justification.

Figure 15 shows the expected residual flood inundation resulting from the closing of the flap-gates and the potential power loss of the pump stations. The economic analysis will determine if the pump stations are economically justified. Other discussions on the interior flooding situation, residual risk, and floodwall superiority can be found in the main report.

9 Floodwall Resilience and Overtopping

In the main feasibility report, Section 8 presents a resiliency discussion. Specific to this appendix, resiliency refers to how well the system performs in case of capacity exceedance or overtopping on the floodwalls. Resiliency was incorporated as a structural measure into the floodwall design by constructing a scour protection apron, as a concrete sidewalk, on the protected side of the floodwall for the purpose of minimizing erosion during flood events that exceed the top of wall elevation. The design floodwall height is not expected to be exceeded until a flood event greater than 0.2% ACE (500-yr) occurs. An extrapolation of the water-surface elevation data by frequency flood event is shown in Figure 16. This figure shows that an event of about 0.13% ACE (750-year) is needed for the floodwall to be overtopped.

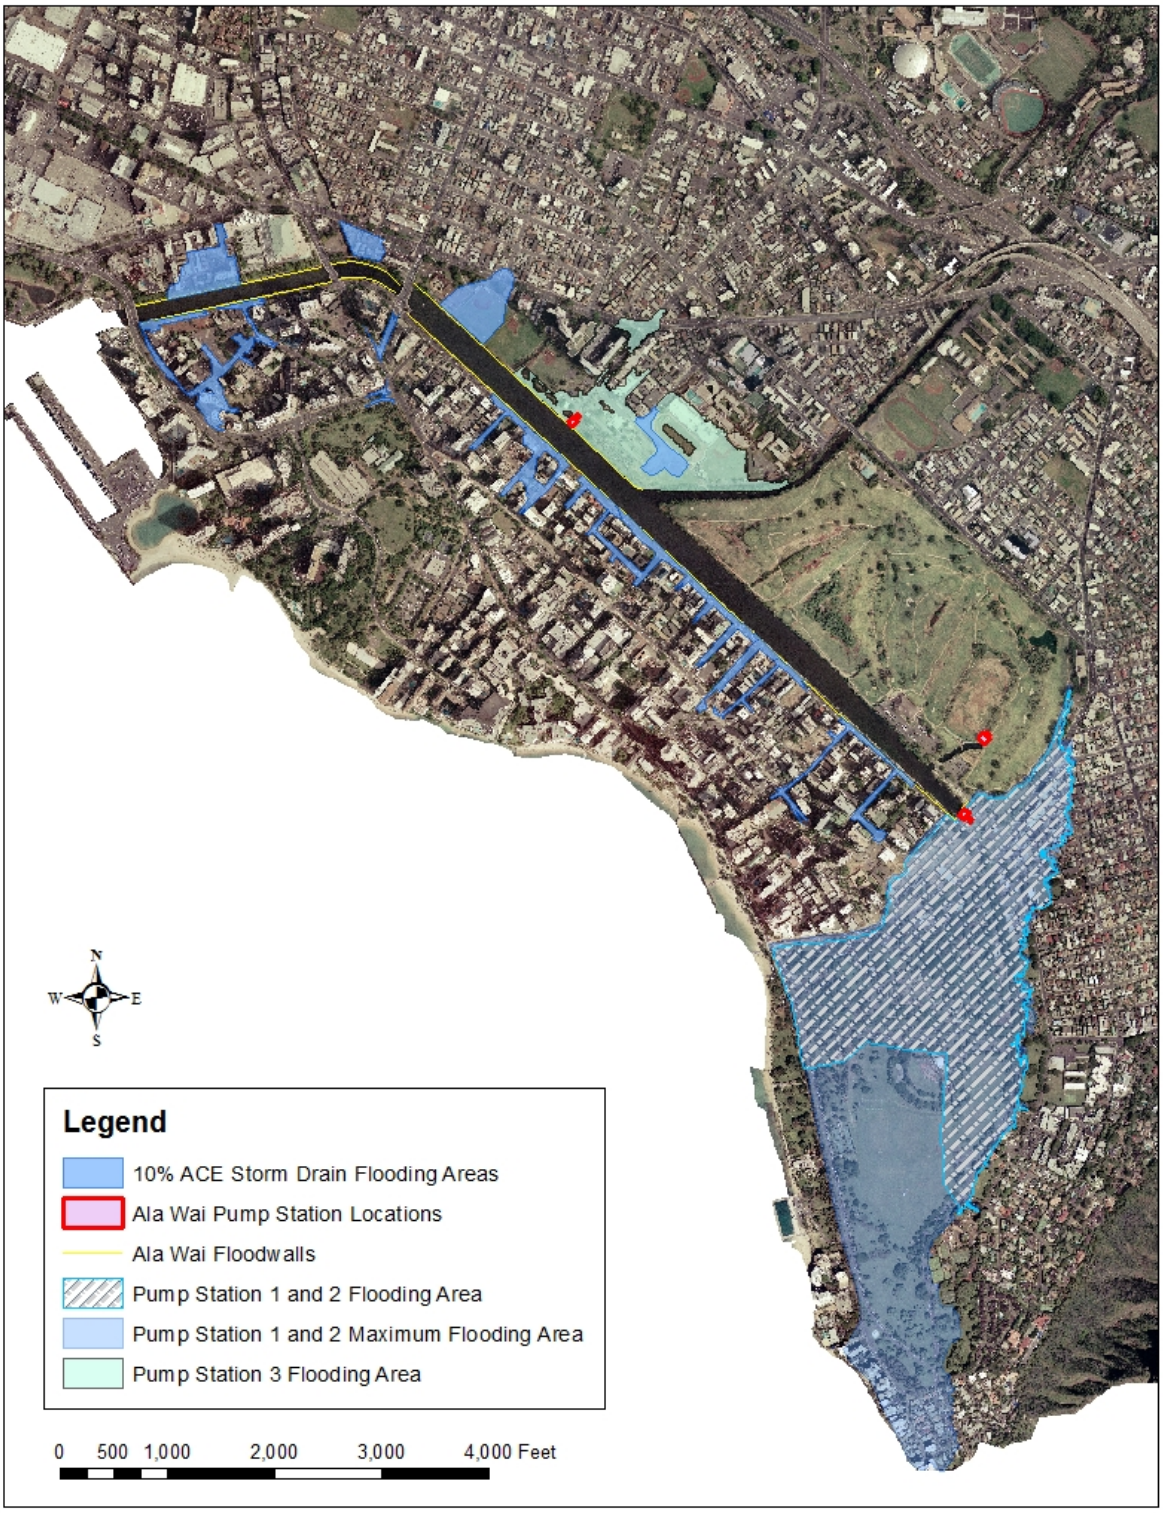

Figure 15. Residual Flood Inundation

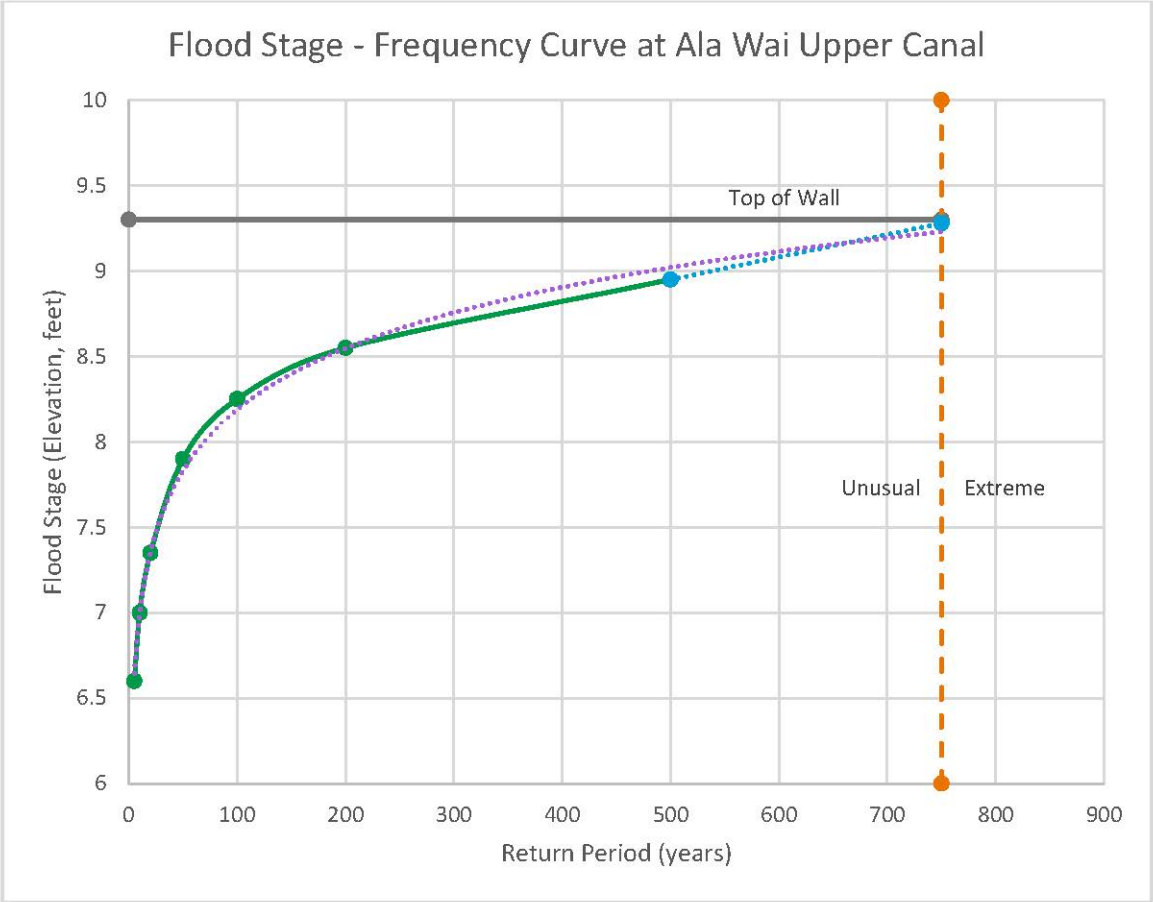

Figure 16. Extrapolated Flood Stage Frequency Curve for Upper Ala Wai Canal Floodwall Reach

10 Coastal Surge, High Sea Level Rise, and Adaptability

The floodwall height values were determined and justified by the optimization process in the National Economic Development (NED) plan development process as described in the main feasibility report and Economic Appendix. This determination was based on riverine flooding and the 2075 intermediate sea level rise backwater condition. To account for coastal surge events, flood wall heights determined for the riverine storm events were also checked versus the potential coastal surge values possible in the Ala Wai Canal regardless of a riverine storm event and also in coincident with a riverine event. This section also discusses floodwall height performance under high sea level conditions out to the year 2125.

Coastal surge or total water values were computed by Patrick O'Brien, P.E., Coastal Engineer Technical Expert with the Climate Preparedness and Resilience Community of Practice. These values, shown in **Table 22**, were computed from tidal data at the Honolulu harbor tide gage.

Table 22. Coastal Surge or Total Water Level values with Sea Level Rise in Feet, Mean Sea Datum

		Intermediate Sea Level Rise			High Sea Level Rise		
ACE (%)	Recurrence interval (year)	2025	2075	2125	2025	2075	2125
100	1.01	1.57	2.33	3.54	1.88	4.27	8.52
50	2	1.88	2.64	3.85	2.19	4.58	8.83
20	5	2.13	2.89	4.10	2.44	4.83	9.08
10	10	2.33	3.09	4.30	2.64	5.03	9.28
5	20	2.56	3.32	4.53	2.87	5.26	9.51
2	50	2.90	3.66	4.87	3.21	5.60	9.85
1	100	3.20	3.96	5.17	3.51	5.90	10.15
0.5	200	3.54	4.30	5.51	3.85	6.24	10.49
0.2	500	4.10	4.84	6.05	4.39	6.78	11.03

Note: Boundary Condition Honolulu/Waikiki Harbor TWL = MHHW + NTR (feet MSL)*
*MSL based on 1983-2001 NTE NOAA 1612340, Honolulu, HI

In comparing the 2075 intermediate and high sea level, 1% ACE total water levels to the floodwall heights determined by the NED process, it is shown in **Figure 17**, the intermediate 2075 case water level is below the floodwall heights for all the Ala Wai Canal reaches. However, the high 2075 1% ACE total water level is higher than the NED determined floodwall heights only at the lower Ala Wai Canal reach, ALA 1. Thus, a coastal event of this magnitude would still cause flooding in the lower Ala Wai Canal reach. To counter this coastal flood risk, the floodwall in the lower Ala Wai Canal reach was raised to 7.9 feet, roughly 2 feet high that the 1% ACE total water level. Note that this total water level does not account for any surge attenuation due to the nearshore coastal bathymetry or reefs. **Table 23** documents the average height change at ALA 1 compared to **Table 20**.

Table 23. Adjusted Average Elevations and Heights of Ala Wai Canal Floodwalls to account for Coastal Surge

	Left Bank		Right Bank	
REACH	Ave. Elev.	Ave. Height	Ave. Elev.	Ave. Height
ALA1	7.9	3.2	7.9	3.1
ALA2	8.5	3.3	8.5	3.4
ALA3	9.3	4.4	NA	NA

Note: Elevation in feet above MSL

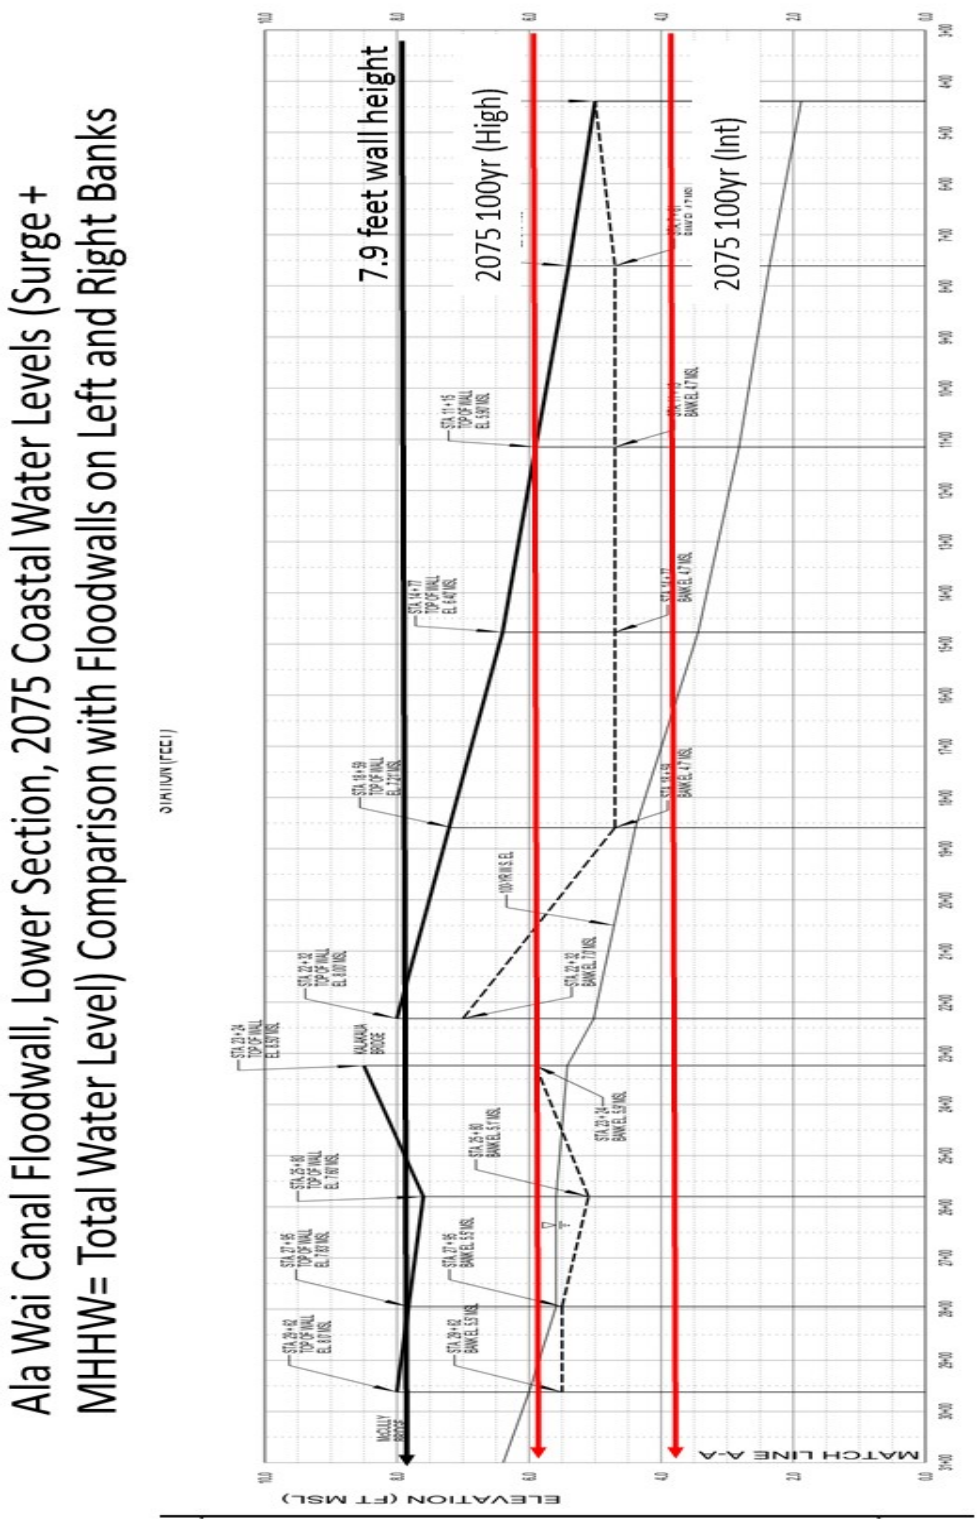

Figure 17. Comparison of 2075 Intermediate and High Coastal Surge Water Level with Floodwall Elevation at the Lower Ala Wai Canal Reach

In addition to coastal surge alone, various coincident scenarios where coastal surge events occur at the same time as riverine events were determined and resulting downstream boundary conditions were computed for these scenarios. Downstream boundary conditions are shown in **Table 24** for these coincident coastal surge and riverine flooding events. All cases have a 1% (100-year) coincident probability, which is the product of the individual probabilities. Case 2.1 is a 10-year (10% ACE) coastal surge for a 10-year (10% ACE) fluvial flow event; Case 2.2 is a 2-year (50% ACE) coastal surge for a 50-year (2% ACE) fluvial flow; Case 2.3 is a 50-year (2% ACE) coastal surge for a 2-year (50% ACE) fluvial flow.

Table 24. Downstream Boundary Conditions for Coastal Coincident Scenarios

Scenario	Recurrence intervals* (year)		Downstream Boundary Condition Elevation		
			2025	2075	2125
Case 2.1	10c / 10f	Intermediate	2.33	3.09	4.30
Case 2.2	2c / 50f		1.88	2.64	3.85
Case 2.3	50c / 2f		2.90	3.66	4.87
Case 2.1	10c / 10f	High	2.64	5.03	9.28
Case 2.2	2c / 50f		2.19	4.58	8.83
Case 2.3	50c / 2f		3.21	5.60	9.85

Note: Elevation in feet above MSL.
*Recurrence intervals: c = coastal surge, f = fluvial flows.
I.e. Case 2.2 = 2-year coastal surge and 50-year fluvial flows.

As discussed in Section 3.1.7 Boundary Conditions and Appendix 3, sea level rise was added to the HEC-RAS models as an increased downstream boundary condition in order to check the floodwall heights under future conditions. To check floodwall height performance, a number of HEC-RAS and HEC-FDA model runs were made using various backwater conditions to cover the wide range of SLR values and scenarios. The backwater scenarios run are shown in **Table 25** with only the high SLR with coastal surge values being added from the values of **Table 5**. Performance data for these various backwater conditions are shown in **Table 26**.

Table 25. Starting Backwater Conditions in Feet for Floodwall Performance Scenarios, Ala Wai Canal Floodwall

Scenario	Without Project		With Project			
Year	Low SLR	Intermediate SLR	Low SLR	Intermediate SLR	High SLR	High SLR with Coastal Surge
2025	1.64	1.74	1.64	1.74	2.05	----

In **Table 26**, the intermediate 2075 SLR scenario is the base scenario representing the NED plan. At these floodwall elevations, the annual exceedance probability (AEP) is close to 1 exceedance in 1000 years at all three index points. Long term risk remains below 1% except for the 50-year periods at damage reach AA 3, where there is a roughly 1.2% chance of at least one overtopping event in 50 years. The conditional non-exceedance probability (CNP) is very high. At the ALA 2 index point, for the 1% ACE flood event there is a 99.96% assurance of not over-topping the floodwall elevation or alternatively, can be stated as 99.96% assurance of containing the 1% ACE event. This assurance CNP does not decrease much for containing the 0.2% ACE event with 99.54% assurance.

Keeping with the ALA 2 index point as the point of comparison, with the intermediate 2125 SLR scenario, assurance remains high, only decreases slightly to 99.63% for the 1% ACE event and to 96.82% for the 0.2% ACE event. With the high 2075 SLR scenario, assurance decreases to 98.53% for the 1% ACE event and to 96.06% for the 0.2% ACE event. Long term risk rises to a 7.77% chance of one or more overtopping events occurring in 50 years. The 1.4 feet increase in starting backwater between the intermediate and high 2075 SLR scenarios translate to an approximate increase of 1.60 feet in the 1% ACE water-surface elevation at ALA 2 index point.

Performance begins to drop in the high SLR with coastal surge 2075 SLR scenario with a starting backwater of 5.60 feet. Assurance at ALA 2 versus the 1% ACE event is 94.55% with the 0.2% ACE event assurance dropping to 91.27%. The 1% ACE event assurance is at the 95% CNP threshold used as a minimum recommended level of assurance for levee/floodwall projects. The 5.60 feet starting backwater represents the highest backwater condition that provides a high level of assurance. At this starting backwater level, the AEP at ALA 2 rises to 0.75% which means the floodwall elevation is close to matching the 1% ACE water-surface elevation. For this scenario, the 1% ACE water-surface elevation is about 1.2 feet below the top of the floodwall. Long term risk rises to 31% chance of one or more overtopping events in 50 years.

Considering the staring backwater of 5.60 feet as the upper limit of assurance, means that for the majority of coastal coincident scenarios (**Table 24**), intermediate and high 2075 SLR and intermediate 2125 SLR scenarios, there is sufficient assurance in the floodwall heights to provide a level of protection in the event these scenarios occur. In scenarios with starting backwater elevations greater than 5.6 feet, such as the high 2125 coastal coincident (**Table 24**) and the high 2125 SLR and 2125 high SLR with coastal surge scenarios (**Table 25**), the NED floodwall heights do not provide sufficient assurance against overtopping. At the ALA 2 index point for the high 2125 SLR scenario, the computed 1% ACE event water-surface elevation is greater than the floodwall height by 0.21 feet. The resulting CNP assurance is only 38.52%, AEP is 51.31% and long-term risk becomes 100% chance of one or more overtopping events starting at 10 years.

If any of the high 2125 scenarios occur, the floodwalls would provide very little protection and would need to be raised as an adaptation measure to provide protection on the north side of the Ala Wai canal. On the south or Waikiki side of the canal, as

discussed in the next paragraph, flooding in Waikiki from SLR and/or coastal surge would negate the need for adaptation of the south side floodwall.

For a discussion on adaptability, SLR conditions with project were computed and mapped. **Figures 18** to **21** show four future scenarios of years 2075 and 2125 with intermediate and high SLR values. Included on these figures are the 1% (100-year) and 0.2% (500-year) floodplains determined by the HEC-RAS model results for each scenario. Sea level rise elevations shown here follows a “low elevation” approach, where any elevations below the designated SLR elevation is shown as holding water. This is regardless of wave action (which would possibly flood more areas) or hydrologic connectivity (which would preclude areas that are not connected to the ocean). From these result maps, it can be seen that the modeled floodwall heights remain effective for retaining 1% ACE (100-year) flood events for the with-project scenario for three of the four scenarios. The highest SLR scenario, year 2125 High, has a SLR elevation of 8.69 feet, and HEC-RAS results show flooding throughout the Waikiki area. However, the majority of this flooded area will experience passive flooding due to SLR, which is not directly linked to flooding of the Ala Wai canal. Thus, in cases except the high SLR 2125 case, floodwall adaptability, in terms of floodwall raise, is not needed. In the high SLR 2125 case, a raise in floodwall would not be sufficient to protect the Waikiki area. Other adaptability measures, such as a coastal barrier, pump stations, retreat or relocation, specific building adaptations, structural fill, and other possibilities, for Waikiki would be needed for that case.

GENERAL NOTES:

1. EXISTING CONDITIONS MAY VARY FROM THOSE SHOWN ON THESE PLANS. THE CONTRACTOR SHALL VERIFY EXISTING CONDITIONS AND ADJUST WORK PLAN ACCORDINGLY PRIOR TO BEGINNING CONSTRUCTION.
2. COORDINATE SYSTEM: NAD 1983 (HARN), HAWAII ZONE 3 (US FEET)
3. PROVIDE FENCING AS NECESSARY TO MAINTAIN SECURITY AT ALL TIMES.
4. UNLESS SHOWN OTHERWISE, ALL DISTURBED AREAS NOT RECEIVING A HARD SURFACE SHALL BE COVERED WITH GRASS.
5. CONTRACTOR SHALL SUBMIT A COMPLETE SOIL EROSION CONTROL PLAN FOR REGULATORY APPROVAL. CONTRACTOR SHALL BE RESPONSIBLE FOR IMPLEMENTING AND MAINTAINING EROSION CONTROL DEVICES DURING CONSTRUCTION. CONTRACTOR SHALL TAKE ALL OTHER MEASURES TO POSITIVELY PRECLUDE EROSION MATERIALS FROM LEAVING THE SITE.
6. EXISTING UNDERGROUND UTILITIES OBTAINED FROM AS-BUILTS AND FROM FIELD SURVEYS. CONTRACTOR SHALL POTHOLE AND FIELD VERIFY DEPTH AND LOCATION PRIOR TO EXCAVATION AND PROTECT ALL EXISTING UTILITIES DURING CONSTRUCTION.
7. THERE WILL BE A FLOODWARNING SYSTEM INSTALLED FOR THIS PROJECT.

GENERAL NOTES:

1. EXISTING CONDITIONS MAY VARY FROM THOSE SHOWN ON THESE PLANS. THE CONTRACTOR SHALL VERIFY EXISTING CONDITIONS AND ADJUST WORK PLAN ACCORDINGLY PRIOR TO BEGINNING CONSTRUCTION.
2. COORDINATE SYSTEM: NAD 1983 (HARN), HAWAII ZONE 3 (US FEET)
3. PROVIDE FENCING AS NECESSARY TO MAINTAIN SECURITY AT ALL TIMES.
4. UNLESS SHOWN OTHERWISE, ALL DISTURBED AREAS NOT RECEIVING A HARD SURFACE SHALL BE COVERED WITH GRASS.
5. CONTRACTOR SHALL SUBMIT A COMPLETE SOIL EROSION CONTROL PLAN FOR REGULATORY APPROVAL. CONTRACTOR SHALL BE RESPONSIBLE FOR IMPLEMENTING AND MAINTAINING EROSION CONTROL DEVICES DURING CONSTRUCTION. CONTRACTOR SHALL TAKE ALL OTHER MEASURES TO POSITIVELY PRECLUDE EROSION MATERIALS FROM LEAVING THE SITE.
6. EXISTING UNDERGROUND UTILITIES OBTAINED FROM AS-BUILTS AND FROM FIELD SURVEYS. CONTRACTOR SHALL POTHOLE AND FIELD VERIFY DEPTH AND LOCATION PRIOR TO EXCAVATION AND PROTECT ALL EXISTING UTILITIES DURING CONSTRUCTION.
7. THERE WILL BE A FLOODWARNING SYSTEM INSTALLED FOR THIS PROJECT.
