FORT SHAFTER, HAWAII

February 2017

(This page intentionally left blank)

Hydrologic and Hydraulic
Climate Change Scenarios for the 50-year (2075)
Future without Project Conditions
Ala Wai Canal Project, Oahu, Hawaii
Fully Revised, February 2017

1.0 Introduction

The US Army Corps of Engineers' (USACE) planning guidance for civil works projects requires that the planning process incorporate a future without project scenario. The guidance also states that the planning process accounts for such future conditions such as climate variability, sea-level rise, subsidence, seismic influences, geomorphological changes, and changes from development which can place demands on the project systems during their life-cycle. Therefore, this document provides three future without-project scenarios for sea level rise for the year 2075 future conditions for the Ala Wai Watershed which will be used in the modeling, selection, and design of project alternatives.

The future without project condition attempts to describe the Ala Wai Watershed's future if there is no federal action taken to solve the flood risk problem. The future condition is fundamentally uncertain and represents a best guess of conditions in the watershed.

2.0 Purpose and Scope

The purpose of this study is to create a future without project scenario for use in the hydrologic and hydraulic analysis for the Ala Wai Canal Project. This report addresses the components of the planning process with emphasis on sea-level rise and how these components impact the hydrologic and hydraulic model results. The resultant future without project floodplains may be incorporated in the economic analysis.

Climate change impacts for Hawaii have been summarized by Fletcher (2010) and more recently in USACE (2015). These changes are rising surface air temperature, decreasing rainfall and streamflow, increasing rainfall intensity, increasing sea level and sea surface temperature, and ocean acidification. For the purposes of hydrologic and hydraulic modeling, the future without-project scenarios will concentrate on the impacts of sea-level rise, increased rainfall frequency, debris generation and transport, and increased impervious area in the Ala Wai Watershed.

3.0 Study Area

The Ala Wai watershed on the Island of Oahu includes the Makiki, Manoa, and Palolo Stream drainage areas as well as the urban Waikiki area which surrounds the Ala Wai Canal (Figure 1). Total drainage area is about 16 square miles. Mean annual rainfall varies from 20 to 150 inches from the coast to the Koolau Crest. Much of the watershed along the canal is relatively flat and subject to flooding from high intensity rainfall storms while the flooding in the Manoa and Palolo Valleys is limited to those areas along the stream. More background information as well as a discussion of the problems and opportunities in the watershed has been documented in previous studies on the Ala Wai Watershed (Townscape and Dashiell, 2003).

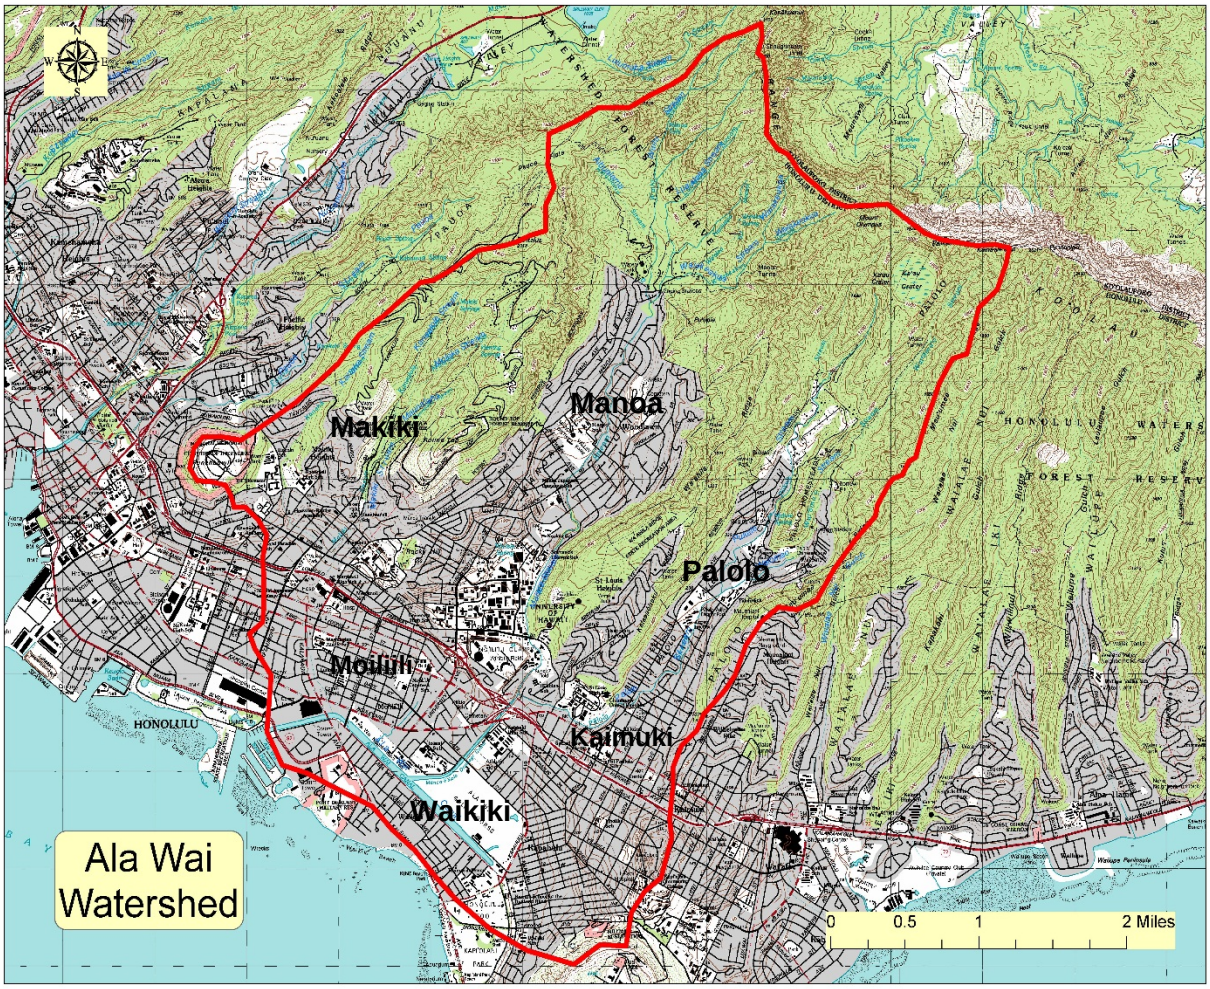

Figure 1. Ala Wai watershed Area

4.0 Methodology and Guidance

The US Army Corps of Engineers' Planning Guidance (Department of the Army, 2000; ER 1105-2-100) for Flood Damage Reduction projects requires a forecast of the future without project condition. This forecast should not exceed beyond 50 years and becomes the basis for evaluation of project alternatives. One of the forecast requirements is to account for future hydrologic changes in the project evaluations. How and what factors to use in the forecast are not discussed in the guidance but left up to the project team to determine.

Sea Level Change (SLC) guidance by USACE has been evolving starting in 2009 with the release of EC 1165-2-211, refined in 2011 as EC 1165-2-212, and finally release as a regulation ER 1100-2-8162 in 2013 (Department of the Army, 2009, 2011, and 2013). These document provide specific guidance to follow in determining sea-level rise in the planning process for projects on the coast or impacted by tidal influences. The computations required for SLC by ER 1100-2-8162 have now been automated by web-based calculator available at http://www.corpsclimate.us/ccaceslcurves.cfm.

For planning purpose, a period of economic analysis also called the period of analysis is chosen. The period of analysis is the time period chosen used to evaluate plan impacts. The period of analysis must be the same for all plans considered in a study as well as the same for all the components of the plan (Yoe and Orth, 1996). Since economic analysis uses a base year for when project benefits start accruing, the forecast period must also start at the same base year. For the Ala Wai watershed project, the base year is 2025. This date is based on a realistic construction start date of 2020 with a 5-year construction time period. Thus, the 50-year forecast period starts at 2025 and ends in 2075.

5.0 Climate Change Impacts and Scenarios:

5.1 Sea-Level Rise

Following SLC guidance, the first steps are to find and determine the applicability of tide station data for the project site. Such data has to be from tide station records longer than 40 years in length. The Honolulu Harbor tide gage, number 1612340, has a long record going back to 1905 and the harbor is located within 2 miles along the coastline to the west of the Ala Wai Canal. There is no dissimilar shoreline, bathymetry or hydrodynamic conditions between the tide station and the canal to disqualify the use of the Honolulu Harbor tide data. Previous tidal data collected in the Ala Wai Canal have shown that the tidal amplitude and phase between the harbor and the canal are nearly identical (Edward K. Noda and Associates, 1992). Thus, this data does adequately represent the local sea-level conditions at the project site.

The guidance recommends the NOAA CO-OPS values for the sea-level trend analysis if such values have been computed for that tide gage. For the Honolulu Harbor tide station, these values have been computed and are available at web site http://www.co-ops.nos.noaa.gov/sltrends. The value for Honolulu Harbor is 1.50 +/- 0.25 mm/year and is based on 100 years of data from 1905-2006. This value is the low or baseline trend rate for the low rise future without-project scenario.

The next step is to calculate a regional mean sea level trend for an identified vertically stable geologic platform in the region to determine if the regional mean sea-level trend is different from the eustatic or global mean sea-level trend of 1.7 +/- 0.5 mm/yr. For the main Hawaiian Island chain, Kauai and Oahu, have been considered relatively stable and this is shown by the very similar tide station trends (Table 1) compared to Maui and Hawaii. Geologic evidence points a slow uplift of Oahu over the last several thousand years resulting from flexural uplift from hotspot loading (Fletcher and Jones, 1996). Rates of uplift have been less than 0.1 mm/yr since the last interglacial period with an estimated mean of 0.06 mm/yr over the last 200,000 years (Fletcher and Jones, 1996; Caccamise, 2003). Given such a low rate of vertical uplift, less than the +/- 0.25 mm/yr uncertainty in the sea-level trend at Honolulu Harbor, the local sea-level trend of 1.50 mm/yr (0.00492 ft/year) was considered to also be the regional mean sea-level trend for Oahu and no vertical land movement was taken into account for determining the future sea-level change.

Table 1. Mean Sea Level Rise Trends in Hawaii

Station Number	Station Location and Island	Period of Record	Years of Record	Computed Trend (mm/yr)
1611400	Nawiliwili, Kauai	1955-2006	52	1.53 +/- 0.59
1612340	Honolulu, Oahu	1905-2006	102	1.50 +/- 0.25
1612480	Mokuoloe, Oahu	1956-2006	51	1.31 +/- 0.72
1615680	Kahului. Maui	1947-2006	60	2.32 +/- 0.53
1617760	Hilo, Hawaii	1927-2006	80	3.27 +/- 0.35

Data from NOAA Tides and Currents website at http://tidesandcurrents.noaa.gov/sltrends/sltrends.shtml (last accessed 4 Feb 2010.

The SLC curve calculator (version 2015.46) uses the modified (National Research Council) NRC Curve I to calculate the intermediate rate of sea-level rise and modified NRC Curve III for the high rate of sea-level rise. These calculations as per guidance are done in 5-year increments starting with 1992 (mid-point of current tidal epoch) as the base year; zero SLC. The results of the low, intermediate and high sea-level rise rates for the Ala Wai Canal study are presented in Table 2. The modified NRC curves are based on NRC scenarios for global sea-level rise adjusted to include the historic sea-level change rate of 1.7 mm/yr presented by the Intergovernmental Panel on Climate Change (IPCC) in 2007 (IPCC, 2007; Solomon and others, 2007).

Table 2. Estimated Rates of Sea-Level Rise for the Ala Wai Canal Project, Oahu, Hawaii

Low Rate (1.50 mm/yr or 0.00492 ft/yr)		Intermediate Rate (NRC Curve I)		High Rate (NRC Curve III)	
Year	Feet	Year	Feet	Year	Feet
2025	0.16	2025	0.26	2025	0.57
2030	0.19	2030	0.32	2030	0.72

2040	0.24	2040	0.44	2040	1.09
2045	0.26	2045	0.51	2045	1.30
2050	0.28	2050	0.59	2050	1.53
2055	0.31	2055	0.66	2055	1.78
2060	0.34	2060	0.75	2060	2.05
2065	0.36	2065	0.83	2065	2.34
2070	0.38	2070	0.93	2070	2.64
2075	0.41	2075	1.02	2075	2.96
2080	0.43	2080	1.12	2080	3.30
2085	0.46	2085	1.23	2085	3.66
2090	0.48	2090	1.34	2090	4.04
2095	0.51	2095	1.45	2095	4.44
2100	0.53	2100	1.57	2100	4.86
2105	0.56	2105	1.69	2105	5.29
2110	0.58	2110	1.82	2110	5.74
2115	0.61	2115	1.95	2115	6.21
2120	0.63	2120	2.09	2120	6.70
2125	0.66	2125	2.23	2125	7.21

Results for the three sea-level rise scenarios (Table 2 and Figure 2) show a range of 0.41 to 2.96 feet in 2075. The intermediate and high sea-level rise rates for 2100 are 0.48 and 1.48 meters (1.57 and 4.86 feet), which falls within the global sea-level rise rates of 0.5 to 1.4 meters by 2100 in the updated studies which account for accelerated glacial ice melting (Fletcher, 2009). Fletcher (2009) makes a case for a 1 meter mean global sea-level rise by 2100 which would eliminate the low rate scenario from consideration in the Ala Wai Canal planning process as being really too low and not a realistic forecast. Thus, the low rate of sea-level rise will not be further considered in project design.

The sea-level rise impacts will be incorporated into the starting backwater conditions of the Ala Wai Canal HEC-RAS model which currently assumes a high tide of 1.08 feet (Mean High High Water (MHHW) from Honolulu Harbor tide gage record, Station 1612340, current epoch) for the current or existing without-project condition for all storm frequencies. The MHHW tidal value represents a long term average at the tide gage. There is an inter-annual variability (IAV) in the data in which year to year variations can result in high tide values higher in some year and lower in others. For the Honolulu Harbor tide gage, the inter-annual variability is about 0.4 feet. Thus, to account for future annual high tide values potentially being higher than MHHW, the IAV value was added to the MHHW as part of the starting backwater conditions. The addition of the IAV makes for a slightly conservative approach, but this addition helps account for future resilience in project design. The various sea-level rise scenarios where then added to the MHHW plus IAV values. Therefore starting water surface elevations for the intermediate and high scenarios will be 1.74 and 2.05 feet in 2025 and 2.50 and 4.44 feet in 2075, respectively. These starting backwater conditions will be used in both the with-out project and with-project future scenarios.

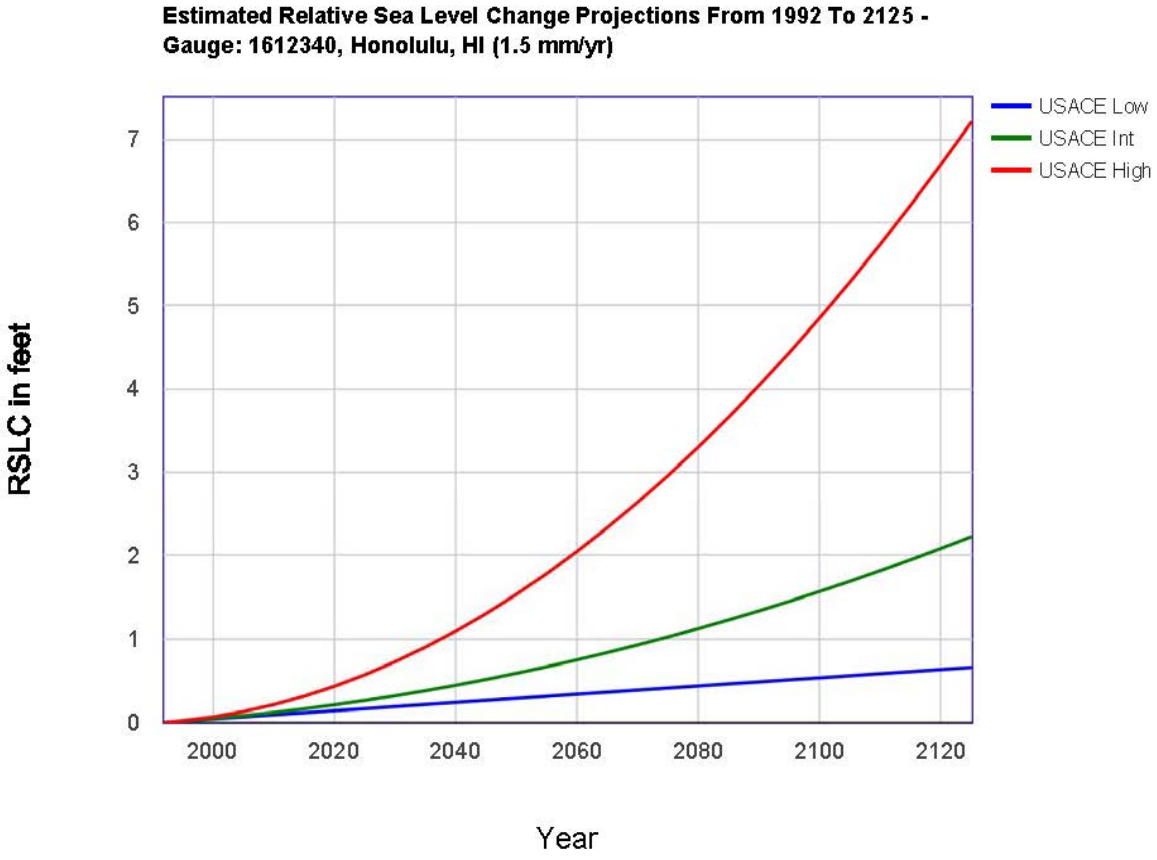

Figure 2. Plot of Relative Sea Level Rise Data in Feet for all Three Scenarios

5.2 Hurricanes

Climate change studies currently indicate that hurricanes would not increase in frequency or movement, but that the intensity of hurricanes that occur could be greater (Christensen and others, 2007; Meehl and others, 2007)). Hurricane strikes to Hawaii and especially Oahu have been rare (Haraguchi, 1984). Because hurricanes are rare in Hawaii, the current hydrological and hydraulic studies for the Ala Wai Watershed project assume no coincidence between hurricanes and the high rainfall intensity flood producing storm systems which are more common. This assumption will also be part of the future without-project condition.

Past hurricane impacts to the Ala Wai Watershed from Hurricanes Iwa in 1982 and Iniki in 1992, have been limited to oceanfront hotel garages below ground being flooded by wave action and road closures of roads fronting these hotels (US Army Corps of Engineers, 1994). Post-hurricane studies have not documented if wave action has had surge impacts to the Ala Wai Canal. Since the mouth of the canal is protected from surge by the Ala Wai Yacht Harbor breakwaters and revetments, surge impacts are assumed minimal. Hurricanes have increased the high tides recorded at tide gages so with sea-level rise, the potential exists that the canal can overtop and cause flooding from hurricanes near Oahu.

Alternatives providing protection from hurricane coastal flooding will not be addressed as part of the Ala Wai Canal project. However, other planning efforts may continue to use the worst-case hurricane condition for southern Oahu until newer studies are conducted (Bretschneider and others, 1985). The worst-case hurricane scenario has inundation limits in Moiliili up to Date Street and in Waikiki into the Ala Wai Golf Course (Bretschneider and others, 1985).

5.3 Rainfall and Runoff

5.3.1 Amount of Rainfall

Regional IPCC results for the North Pacific region (Christensen and others, 2007; page 915) show an estimated decrease of 0 to -5 percent in annual rainfall for Oahu due to estimated temperature increase in the Northern Pacific by 2080-2099. The estimated decrease is -5 to -10 percent for the winter months of December, January, and February (Christensen and others, 2007; page 915). The decadal scale regional climatic feature of El-Nino Southern Oscillation (ENSO) already create drier than normal winter months so the impact on water supply, which is dependent on the tradewind rainfall patterns, will be aggravated when ENSO events occur with the estimated decrease in rainfall. A decrease in rainfall will have an impact to water supply on Oahu, which is highly dependent on ground water wells for drinking water, as rainfall is an important component of ground-water recharge. Sea-level rise will also impact groundwater resources by decreasing the freshwater lens or available amount of freshwater which can be pumped without causing saltwater intrusion. Therefore, water supply planning may look into large and small scale rain catchment or some means to catch storm runoff and store for later non-potable use.

5.3.2 Rainfall Frequency and Intensity

According to the report: Global Climate Change Impacts in the United States (2009, p. 32), from 1958-2007, very heavy precipitation, defined as the heaviest 1 percent of all daily rain events, has increased by 12 percent for the State of Hawaii. The average number of days with heavy precipitation has increased by 8 percent for the State of Hawaii. It is expected that the frequency of heavy rainfall events will increase while the lightest precipitation is projected to decrease. The 5 percent chance (20-year) storm is expected to be between 10 to 25 percent heavier by the end of the 21st century (Global Climate Change Impacts in the United States, 2009, p. 32). It is unknown if decadal events such as ENSO variations can temper the expected increase in heavy precipitation. More recent studies show that this projected increase in heavy rainfall events is not supported by statistical trend analysis or the downscaling of the global circulation models to Hawaii.

Chu and others (2010) looked at extreme rainfall events using statistical trend analysis techniques on daily rainfall data from 2 different time periods, 1950-79 and 1980-2007 at 37 to 65 raingages in Hawaii. Trends of interest for the future without project condition concern the number of wet days, defined as any day with greater than 1 mm of precipitation and the frequency of intense precipitation, defined as the annual total of days with greater than 1 inch of rainfall. For the raingages on the Island of Oahu located in Manoa Valley that were part of their study, there were an insignificant downward trend in the frequency of intense precipitation between the two time periods. Elison Timm and others (2011) investigated trends in the frequency of heavy rainfall events in relation to statistical downscaling of global climate models. This study defined heavy rain events as the 95% quantile in the rainfall distribution during the October to April wet season. Results of the trend analysis indicates that at 9 out of 12 statewide rain gages analyzed in the study there was a downward trend in the frequency of heavy rainfall events. The Honolulu Airport rain gage, was one that did show a downward trend. Other results were that the interannual to interdecadel variability is significantly related to ENSO Southern Oscillation Index (SOI) and that the downscaled results from the global climate models are unable to account for the ENSO variations.

Norton and others (2011) use a nonlinear artificial neural networks statistical model to downscale daily extreme precipitation events on Oahu from global circulation model outputs. Their results show a tendency for increased frequency of heavy rainfall events but a decrease in rainfall intensity during the next 30 years (2011-2040) for the southern shoreline of Oahu. The most recent work on this topic is Elison Timm and others (2013) in which a statistical downscaling method is used to project future shifts in the frequency of heavy rainfall events. In this paper, heavy rain events are defined as days with rainfall amounts exceeding the 90th percentile estimated from all wet season days from 1958-2010. Their statistical downscaling model was able to reproduce the interannual variability in heavy rain events for the period 1978-2010. When applied to global circulation models scenarios, their model predicted a low likelihood of increased heavy rain events in Hawaii over the remainder of this century.

Therefore, based on the results of these studies on changes to heavy rain events in Hawaii, it is assumed for the future without project scenario that there will be no change to the rainfall frequency intensity data from that used in the without project condition.

5.4 Debris Generation

One impact of large intense rainfall storms in Hawaii has been debris generation, both from vegetation and hill slope and channel erosion sources, which can impact the ability of stream channels and stream crossing structures to function as designed. In general, narrow streams rarely transport large floating debris that can block bridges. Large floating debris usually gets trapped or lodged across the channel and rarely moves without being broken into smaller pieces. Small and intermediate size floating debris becomes an issue where bridge piers or other obstructions occur, due to the potential of significant debris pile-ups on piers. Streams in the Ala Wai Watershed have steep channel slopes and exhibit rapid responses to rainfall, “flash floods”, which tend to have a large amount of energy which can move large boulders or rapidly erode sections of stream bank or channel. This type of debris also has the potential to create blockages in the stream channels or reduce the ability of bridges to pass flood flows. One method of account for debris or sediment in runoff is the use of a bulking factor. The bulking factor is just an increase in the Manning’s n-value, which is used to represent channel roughness in the hydraulic model. Normally, the higher the n-value used, the higher the resulting water-surface elevation, thus, the term bulking. Normally a percentage increase, like 10- or 20-percent is used to account for debris in the flood flows.

The ability to predict the amount of debris generated by any future storm event is pure speculation. Although debris volume estimates are made to assist in debris basin sizing, such volume estimates did not account for the sediment or floating debris that passes through the basin or are generated downstream of the basin, so are not as useful as the bulking factor to account for suspended sediment and floating debris. For the future without project scenarios, it is difficult at best to make any guesses that debris amount will be larger or smaller in the future. Assuming the same land-use in 2070 as today, the amount of generated debris should not significantly change from those estimates used in the current without-project conditions models. Assuming such efforts as invasive species removal, feral pig control, stream clean-ups, and restoration of riparian vegetation are to be done in the future as smaller locally based projects, then the amount of debris generated will potentially decrease. Therefore, the future without-project scenario will look at no increase in debris generation.

5.5 Increased impervious Area

The Ala Wai Watershed is already a densely developed urban area. Residential land use dominates in the Makiki, Manoa, and Palolo areas with smaller areas of commercial activities. Waikiki is highly developed with high rise hotels and apartment buildings. Population in the watershed is not expected to increase significantly in the future. In fact a future with a decreasing quality of life may lead to population decrease in Hawaii. Future construction is assumed to continue the current trend which consists of rebuilding on existing lots, possibly with higher density residential units which may add a minimal contribution to runoff. Current observation in the Kaimuki and Palolo areas,

show a slow replacement of smaller single family homes with modern double wall construction 2-story homes having larger footprints. At a specific house lot then, there would be less open space for infiltration and potentially move direct connections from roof to street. The overall impact to runoff is small but potentially cumulative over time. Such redevelopment impacts can be mitigated through low-impact development ideas to be used in new construction or as a requirement for the watershed. Therefore, the future without-project scenario may see a small increase in runoff from urban areas but this increase cannot be quantified.

6.0 Summary

The future without project condition attempts to describe the Ala Wai Watershed's future if there is no federal action taken to solve the flood risk problem. The future condition is fundamentally uncertain and represents a best guess of conditions in the watershed. Planning guidance states that the planning process accounts for such future conditions such as climate variability, sea-level rise, subsidence, seismic influences, geomorphological changes, and changes from development which can place demands on the project systems during their life-cycle. Therefore this document provides a qualitative discussion on the future hydrologic and hydraulic impacts of sea-level rise, increased rainfall frequency, debris generation and transport, and increased impervious area for the 2075 future condition.

The only quantitative analysis will be to incorporate sea level rise in the economic analysis, modeling, selection, and design of project alternatives. Using the intermediate sea level rise rate as the most probable future, the backwater conditions in the HEC-RAS model will be increased to 2.50 feet from 1.08 feet to account for future sea level rise in the future without-project scenario. Both the intermediate and high sea level rise rates will be used in the modeling to analyze project performance in the future with-project analysis for years 2075 and 2125.

Introduction

The Ala Wai Canal Flood Risk Management project is located on the island of Oahu in urbanized Honolulu, Hawaii. The project would protect metropolitan Honolulu, the University of Hawaii, and Waikiki, Hawaii's economic center for tourism. The population at risk includes approximately 65,000 residents and an additional 200,000 transient visitors to the watershed daily (tourists, workers, students, etc.). Project features originally included the following eleven individual structural elements and two non-structural components as carried forward from the feasibility study tentatively selected plan include:

- Six debris/detention basins in upper stream reaches
- One stand-alone debris catchment structure
- Three multi-purpose detention basins
- Floodwalls along Ala Wai Canal (including pump stations for interior drainage)
- Flood warning system (non-structural)
- Fish and wildlife mitigation (non-structural)

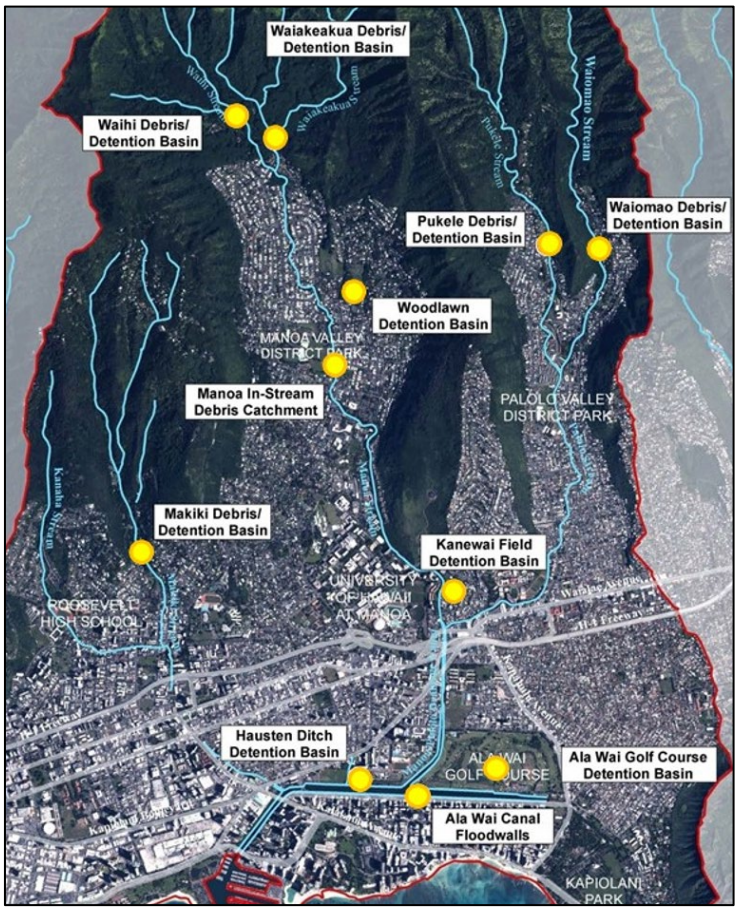

Figure 1: Feasibility Study TSP

At the time of this report project features now include:

- Three multi-purpose detention basins (Kanewai, Golf Course, and Hausten Ditch)
- Two stream diversion features (Woodlawn Bridge and the Makiki Cannel Diversion)
- Floodwalls along Ala Wai Canal (including pump stations for interior drainage)
- Flood warning system (non-structural)
- Fish and wildlife mitigation (non-structural)

Basin Description

The Ala Wai Watershed encompasses approximately 16.2 square miles and includes the drainages of Manoa, Palolo, Makiki, McCully, Moiliili, and Waikiki. The Manoa and Palolo streams join to form the Manoa-Pololo Canal. The Manoa-Pololo Canal, Makiki Stream, and three low lying drainage areas empty into the Ala Wai Canal, a two-mile long, man-made waterway constructed in the 1920s to drain wetlands, allowing the development of the Waikiki area.

The upper reaches of the basin are very steep and rocky and incised into the Ko'olau Volcano. This portion of the watershed ranges from 40 to approximately 2400 feet in elevation. The Makiki and Manoa basins typically receive more than 160 inches of rain annually, while the Pololo valley receives less. See below for the Rainfall Atlas of Hawaii by the University of Hawaii for average annual precipitation.

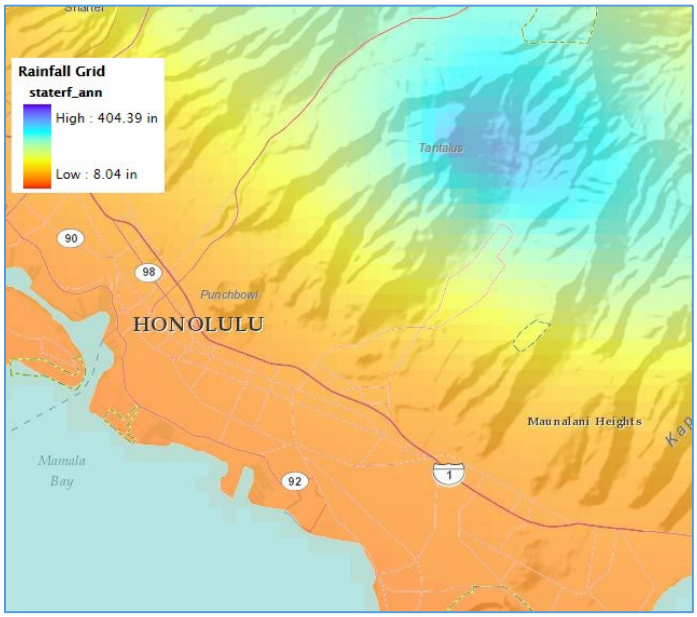

Figure 2: Mean Annual Rainfall-Rainfall Atlas of Hawaii (Giambelluca, 2013)

The lower portion of the basin is much less steep and is extremely urbanized. Significant portions of this are impervious surfaces, with sewer system drainage actively directing most of the runoff in less intense events. The Ala Wai Canal and Waikiki basin receives about 30 inches of annual rainfall. High-Intensity rainfall on steep slopes of the small drainage basin can produce very flashy flood events in the lower basin. Time to peak is usually less than 1 hour and even for large intense storms, the rise and recession of the flood hydrograph usually occurs with 6 hours.

The Ala Wai canal overtopped and previously flooded Waikiki during the November 1965 and December 1967 storms, as well as during the passage of Hurricane Iniki in 1992. In October 2004, a storm flooded Manoa Valley, causing $85M in damages to the University of Hawaii, including the loss of irreplaceable documents in one of the libraries. Additional flooding occurred in the 2006 rain event. Early modeling efforts indicated that a one percent annual flood exceedance event would result in damages to more than 3,000 structures in the watershed, with total damages of over $1.14B, with much of the damage in the downstream area of Waikiki. However, this modeling was done before significant technological modeling advancements in this last decade and this study is an effort to update this work.

Previous Modeling Efforts

A hydrologic model of the watershed was developed in 2008 by Oceanit. Modifications were made to the model and report in March 2016, August 2016, and February 2017. This effort is detailed in the *Ala Wai Canal Flood Risk Management Study O'ahu, Hawai'I Final Feasibility Study Report with integrated Environmental Impact Statement* Appendix A – Hydrology and Engineering.

A list of previous reports with descriptions is included in section 2.2 "previous hydrologic and hydraulic models and studies." These include:

- Federal Emergency Management Agency's National Flood Insurance Program Study (FEMA, 1979)
- Ala Wai Canal Improvement Project, Storm Water Capacity Study (Edward K. Noda and Associates, 1994)
- Ala Wai Flood Study (USACE, 2001)
- Ala Wai Watershed Analysis (Townscape Inc. and Dashiell, 2003)
- Hydrology and Hydraulics Study, Flood of October 30, 2004, Manoa Stream (USACE, 2006)
- Final Hydrology Report, Manoa Watershed Project (Oceanit 2008a)
- Final Hydraulic Analysis Report, Manoa Watershed Project (Oceanit, 2008b)
- Technical Summary Report, Manoa Watershed Project (Oceanit, 2008c)
- Final Hydrology Report, Ala Wai Watershed Project (Oceanit, 2008d)
- Final Drainage Evaluation Report, Ala Wai Canal Watershed Project (Oceanit, 2008e)
- Conceptual Engineering Report, Ala Wai Canal Flushing System & Ala Wai Golf Course Detention System (Mitsunaga & Associates, Inc., 2014)

The 2008 Oceanit study focused on the HEC-HMS model, but utilized five different methods to estimate peak flow discharges throughout the Ala Wai Watershed for various frequency storms. Estimated peak flow discharges were based on the existing conditions of the Ala Wai Watershed. Oceanit modeled storms using both rainfall-runoff and peak flow frequency methods for a range of storm scenarios. The study researched and collected relevant hydrologic data; constructed and calibrated both rainfall-runoff and peak flow frequency hydrologic models; and weighted and compared the results from these models to arrive at estimated peak flow discharges.

Data collected included rainfall and stream gage data, historical storm data, drainage system information, geospatial data for basin characteristics, and field and other local observations. This data

was used to build and calibrate a HEC-HMS model, which simulates rainfall-runoff behaviors for the Ala Wai Basin. This model was used to route Atlas 14 frequency rainfall data (A NOAA dataset that provides rainfall volumes by duration throughout the United States) using losses from SCS numbers, Clark Unit Hydrographs as the transform method in the upper basin, and Kinematic wave in the lower basin.

Alternate flow calculation methods included the USGS (United States Geological Survey-a science based bureau within the Department of the Interior) regression method (peak flow only), City and County of Honolulu drainage standards (peak only), FEMA (Federal Emergency Management Agency) Flood Insurance Study data, and Statistical Analysis of data where available.

This data was weighted to determine a final peak flow discharge at specific locations within the watershed at the 2-, 5-, 10-, 20-, 50-, 100-, 200-, and 500-year events. These are otherwise listed as the 50, 20, 10, 5, 2, 1, 0.5, and 0.2 percent probability events. The 100-year event is the event that has a 1 in a hundred chance happening each year and does not typically occur in a one-hundred-year cycle. Therefore, for the rest of this report the frequency events will be referred to as an Annual Exceedance Probability (AEP) or percent probability event.

Table 1: Equivalent Frequency Terms

1 Year Event	1 AEP	100% Probability	100% AEP
2 Year Event	0.5 AEP	50% Probability	50% AEP
5 Year Event	0.2 AEP	20% Probability	20% AEP
10 Year Event	0.1 AEP	10% Probability	10% AEP
20 Year Event	0.05 AEP	5% Probability	5% AEP
50 Year Event	0.02 AEP	2% Probability	2% AEP
100 Year Event	0.01 AEP	1% Probability	1% AEP
200 Year Event	0.005 AEP	0.5% Probability	0.5% AEP
500 Year Event	0.002 AEP	0.2% Probability	0.2% AEP

Project Scope

In an effort to improve upon and extend previous modeling efforts the following adjustments were scoped for the 2018-2020 initial Ala Wai Hydrology Efforts:

- Update model to the most recent published version (HEC-HMS Version 4.3)
- Sub-basin adjustments and recalibration to better match exact locations of future upstream detention basins and HEC-RAS model inputs.
- Creation of alternative geometries for a peaked and non-peaked routing, including the applications of peaking factors (25%, 33.3%, and 50%) for use in routing the Probable Maximum Precipitation.
- Creation of Probable Maximum Precipitation (PMP) using HMR 39 methodology to include an:
    - Entire Basin PMP
    - Individual PMP for the six upstream detention basins
- Completion of various PMP Sensitivities.
- Routing of final PMF and Frequency Events with alternative geometries.
- Routing uncertainty simulation for upper and lower bounds
- Compiling a final report for inclusion with the hydraulics updates.

As will be detailed in this report, upper basin project features have largely been removed and a single without project geometry was continued for the final frequency, uncertainty, and PMF routings. No

project features are routed in the HEC-HMS model. Therefore, the final scope of this project is listed below.

- Update model to the most recent published version at beginning of study (HEC-HMS Version 4.3)
- Sub-basin adjustments and validation of calibration of the HEC-HMS model to better match HEC-RAS model input locations. These locations need to match as closely as is reasonable to most accurately route flows. Creation of a simplified HEC-HMS model with uncertainty for faster run times in the HEC-WAT Model.
- Routing of feasibility rainfall frequencies for comparison to previous study
- Creation of a HEC-WAT model with a hydraulic sampler, HEC-RAS model, and duration plug-in. The hydraulic sampler shall sample storm events local to the basin and Atlas 14 volumes. The HMS model will be simplified as much as reasonable for runtime speed and linked to the hydrologic sampler. The Duration plug-in will be set to output various duration flows at specified locations for use in the HEC-RAS model.
- Routing of the HEC-WAT model a sufficient number of times to define uncertainty bounds up to the 0.2 Annual Chance Exceedance (500-year event).
- Creation of an HEC-SSP model to distill the HEC-WAT data into hydrographs usable in HEC-RAS modeling for final frequency routings.
- Determination of hydrologic uncertainty parameters for use in HEC-FDA.
- Compiling a final report for inclusion with the hydraulics modeling updates.

Frequency Method and Results Overview

For this effort, final frequency flow data was created for use in the HEC-RAS (hydraulic modeling) and HEC-FDA (economic modeling) models for use in design decisions and cost-benefit analyses. A brief explanation of the process used to create this frequency data is listed below. Additional details of this process are in later chapters of this report.

1. Rainfall Frequency data was populated.
    a. This data was pulled graphically from gridded Atlas 14 precipitation-frequency data and processed using zonal statistics in ArcMap to get a basin average value. This gridded data was collected for the 12-and 24-hour durations. Upper and lower confidence limit data were also collected with the associated estimated record length (ERL). The ERL data was tested for how well it reproduced the uncertainty bands.
    b. Atlas 14 provides a value for point precipitation, so to reduce this to a basin wide value, Table 6-6 in Hydrometeorological Report (HMR) 39 was used (the Probable Maximum Flood guidance document in the state of Hawaii) for Depth Area Reduction.
    c. Five temporal/spatial patterns were developed which include 3 observed storm events (2004, 2006, 1967), an observed temporal pattern from 1958 paired with the Atlas 14 spatial pattern, and a synthetic storm shape developed using HMR39 temporal pattern B., The HEC-WAT (Monte-Carlo Analysis tool) selects one of these storm templates for each iteration and scales it to match the sampled precipitation volume for that iteration.
2. A HEC-HMS model (hydrologic routing model) was updated for use in this study.

   a. The basin was analyzed to determine soil conditions, slopes, land cover and use to determine empirical first guess runoff calculations. This was done as part of the feasibility study.
   b. The rainfall from the three calibration events (2004, 2006, 1967) were imported into the model and run through the empirical equations. This was done as part of the feasibility study. These events were selected as they are the largest events that had reasonable (but still limited) rainfall and stream gage data readily available.
   c. These equations were altered within a band of reasonable values to best match stream data, where available to calibrate to this gage data. This was done as part of the feasibility study.
   d. The feasibility basin configuration was adjusted slightly to meet the needs of the current study's HEC-RAS inflow boundary condition points.
   e. Verification testing was performed to ensure that the minor alterations to the basin configuration did not significantly affect modeled flows.
3. Uncertainty needed to be quantified for the discharge frequency calculations and is required by EM 1110-2-1619, chapter 4. This has also been reinforced by ER 1105-2-101. This uncertainty was added to the rainfall data and HEC-HMS model.
   a. Uncertainty data from rainfall was collected as discussed in item 1a-c.
   b. Uncertainty in the rainfall runoff was estimated though varying the loss rates (loss rates were set to randomly sample between values associated with a range of land uses one band higher and one band lower than the reported field values. (i.e. moderate to highly urbanized, or various levels of plant cover in a forested region)
4. A HEC-WAT (Watershed Analysis Tool) was developed and used to characterize uncertainty.
   a. HEC-WAT is a model linking and sampling tool, it samples the ranges of values specified and runs many times to determine a distribution of values.
   b. The area-reduced basin-averaged precipitation is added to the model with the ERL data. This allows the model to sample precipitation volumes between the uncertainty bands.
   c. The template storms from item 1c are loaded into the WAT interface.
   d. The HMS model is loaded into the WAT and is linked to the precipitation data in 4b and c. The uncertainty data associated with the loss rates is turned on.
   e. A "duration plugin" script was set up to report the output flows at each specified duration. (peak, 1-hour, 2-hour, 4-hour, etc.)
   f. The WAT was then run for 60,000 iterations.
   g. Peak outflows for the HEC-RAS inflow locations are show in the table below.
5. The HEC- SSP (Statistical Software Package) was used to develop balanced hydrographs for use in the HEC-RAS model.
   a. This process takes the HEC-WAT output and turns it into a format HEC-RAS can ingest. For this study HEC-RAS was used for stream flow routing due to backwater effects at the more extreme frequency events.
      WAT flow-frequency-duration outputs were computed for the mean or expected value for all frequencies and the confidence limits for the 0.01 AEP only.
   b. The HEC-WAT 50%, 20%, 10%, 5%, 2%, 1%, 0.5%, and 0.2% AEP flow values were entered into HEC-SSP for each duration(0.02-, 1-, 2-, 4-, 8-, 10-, and 12-hours) for each HEC-RAS inflow point.
   c. A hydrograph shape derived from the feasibility HMS model was used as a template for each subbasin and was loaded into HEC-SSP as a Flow Data Set.

d. Hypothetical hydrographs were created that "balanced" flow volume, from the HEC-WAT duration plugin, with frequency across multiple durations while preserving the peak runoff timing.
e. This process is needed because, while the HEC-WAT has many storm routings and output data, they are each individually using a temporal pattern from different storm events and need to be simplified to a single neutral pattern. The balanced hydrographs are now ready for ingestion into the HEC-RAS model for final routing with all backwater effects, overland flow, and other more complex flow schema. A sample series of balanced hydrographs is shown below.

Table 3: Peak Flows for 1% Annual Exceedance Probability at HEC-RAS Inflow Points

Guidance Documents

Various guidance documents are referred to within this report. The documents shape the methodology required for this study. These include:

- Engineering Manual 1110-2-1619 Risk Based Analysis for Flood Damage Reduction Studies
- Engineering Regulation 1105-2-101 Risk Analysis for Flood Risk Management
- Engineer Manual 1110-2-1411 Standard Project Flood Determination
- Engineer Regulation 1110-8-2 (FR) Inflow Design Floods for Dams and Reservoirs
- Engineer Manual 1110-2-1417 Flood Runoff Analysis
- Hydrometeorological Report No. 39 (HMR 39) Probably Maximum Precipitation in the Hawaiian Islands
- NOAA Atlas 14 Point Precipitation Frequency Estimates, Precipitation-Frequency Atlas of the United States Volume 4 Version 3
- Technical Paper 40 (TP40) Rainfall Atlas of the United States for Durations from 30 minutes to 24 hours and Return Periods from 1 to 100 years
- HEC-WAT Water Analysis Tool User's Manual
- HEC-WAT Hydraulic Sampler User's Manual
- HEC-SSP Statistical Software Package User's Manual

- HEC-HMS Hydrologic Modeling System User's Manual

Standard Units

Unless otherwise specified all units are as follows:

Precipitation- Inches (In)

Flow – Cubic Feet per Second (CFS)

Runoff Volume – Inches (averaged over the upstream drainage area of a given point)

Area- Square Mile (mi^2)

Elevation- Feet, Local Tidal Datum-mean sea level, Tidal Epoch 1983-2001. Goid 2012A

Projection- NAD 1983 HARN projected to State Plane Hawaii 3 FIPS 5103 feet, Horizontal

Plain Writing Act

The Plain Writing Act of 2010 directs government agencies to use clear and concise language for better public understanding. The writer will attempt to follow the Federal Plain Language Guidelines as much as the subject matter will allow.

Rainfall Frequency (Atlas 14)

Table 4-1 of EM-1110-2-1619 describes the available options for the calculations of discharge probability functions without recorded events. There are not enough gage data to use the direct analytical method described in the regulations at all inflow points to the HEC-RAS model in the basin. Continuous simulation is a significant effort beyond the hypothetical frequency events method and is typically only used in very high-risk situations.

For the very flashy or fast-moving storms that occur in this basin, a rainfall-runoff calculation method that produces hydrographs instead of only peak flow estimates is required. This is because the basin will not reach equilibrium or a steady state at the peak of the storm hydrographs. (The water is moving through the system too rapidly and there is not enough rainfall volume to completely flood all areas associated with equilibrium.) A hydrograph is also required as an input for the updated two-dimensional (2D) hydraulic modeling. Therefore, only the hypothetical frequency events options in the below table is reasonable to use for inputs into the HEC-RAS model. NOAA Atlas 14 is the most widely used rainfall frequency dataset.

Table 4-1
Procedures for Estimating Discharge-Probability Function Without Recorded Events (adapted from USWRC (1981))

Method	Summary of Procedure
Transfer	Discharge-probability function is derived from discharge sample at nearby stream. Each quantile (discharge value for specified probability) is extrapolated or interpolated for the location of interest.
Regional estimation of individual quantiles or of function parameters	Discharge-probability functions are derived from discharge samples at nearby gauged locations. Then the function parameters or individual quantiles are related to measurable catchment, channel, or climatic characteristics via regression analysis. The resulting predictive equations are used to estimate function parameters or quantiles for the location of interest.
Empirical equations	Quantile (flow or stage) is computed from precipitation with a simple empirical equation. Typically, the probability of discharge and precipitation are assumed equal.
Hypothetical frequency events	Unique discharge hydrographs due to storms of specified probabilities and temporal and areal distributions are computed with a rainfall-runoff model. Results are calibrated to observed events or discharge-probability relations at gauged locations so that probability of peak hydrograph equals storm probability.
Continuous simulation	Continuous record of discharge is computed from continuous record of precipitation with rainfall-runoff model, and annual discharge peaks are identified. The function is fitted to series of annual hydrograph peaks, using statistical analysis procedures.

Figure 4: Discharge Probability Options

Rainfall Frequency Data Used

National Oceanic and Atmospheric Administration (NOAA) Atlas 14 are the official precipitation frequency estimates for the United States. This dataset includes the rainfall frequency and intensity with 90 percent confidence intervals for the 1 to 0.001 AEP rainfall events for durations from 5 minutes to 60 days. Documentation can be found at: http://www.nws.noaa.gov/oh/hdsc/PF_documents/Atlas14_Volume4.pdf, while the actual server is located at: http://hdsc.nws.noaa.gov/hdsc/pfds/hi/hi_pfds.html. This data is used for this study as it provides the means to produce hyetographs for an entire frequency storm event, instead of single peak value. The updated hydraulic (HEC-RAS) modeling requires a time series of data, rather than a static point, so that rainfall can be converted to stream flow, then routed through the basin throughout the storm. This is an improvement to the previous study, which simply assumed that all peak flows occurred at the same time for long enough to create a steady state in the basin.

During the feasibility study, the updated rainfall frequency data for the State of Hawaii was released March 30, 2009 on the Precipitation Frequency Data Server (PFDS) which is part of NOAA Atlas 14, Volume 4, Version 2.0, Hawaiian Islands. This precipitation data was taken from a point at the centroid of the watershed and documented in the feasibility report. Table 4 shows the 2009 best estimate rainfall data below.

Post feasibility study, an update to the Atlas 14 Volume 4 document and the n-minute scaling factors (adjustments to precipitation at less than one hour) was released in 2011. This updated data was analyzed graphically to find subbasin averaged precipitation volume and is what is used for the final frequency analyses in this report. Table 8 shows the final rainfall data for this study below.

It should also be noted that this rainfall frequency was not developed with only recent data, but includes a relatively long period of record, and encompasses notable historic events. In fact, there were quite a few gages in the Ala Wai region by 1905. A reporting of this method and rather large list of precipitation

data is in the Altas-14 documentation at the link above. Due to the methodology used to analyze the gage data, an estimated number of data years of 310 was published in the Atlas 14 document for the Honolulu Area.

Table 4: Feasibility Study: 2009 NOAA Atlas 14 Rainfall Frequencies

Percent Chance Exceedance	Return Period (years)	Depth (inches) for Specified Duration								
		5-min	15-min	30-min	1-hour	2-hours	3-hours	6-hours	12-hours	24-hours
99	1	0.38	0.66	0.97	1.40	1.87	2.12	2.74	3.35	3.92

5	20	0.81	1.49	2.11	3.05	4.15	4.94	6.28	8.00	9.95
4	25	0.89	1.52	2.25	3.24	4.42	5.16	6.69	8.36	10.42
2	50	1.02	1.75	2.59	3.74	5.09	5.94	7.69	9.61	12.05
1	100	1.16	1.99	2.95	4.25	5.78	6.74	8.74	10.92	13.77
0.5	200	1.31	2.25	3.34	4.82	6.53	7.61	9.86	12.30	15.60
0.2	500	1.53	2.62	3.88	5.61	7.57	8.82	11.42	14.23	18.18

Rainfall Intensity Frequency data determined from NOAA Atlas 14 Precipitation Frequency Data Server using watershed centroid of 21.3092 N, 157.8071 W. Values for the 5-percent chance storm are interpolated.

Atlas 14 Volume 4 Data Analyses and Frequency Determination

NOAA uses a detailed process to screen data and produce final best estimate frequency data determinations. The process for Hawaii is dissimilar to Atlas 14 data calculated for the continental United States. A general overview of the process to determine best estimate annual maximum series-based precipitation frequency volumes is as follows:

Precipitation frequency estimates have been computed for a range of frequencies and durations using a regional frequency analysis (which means trading space for time) using statistics on the peak annual rainfall data. This included precipitation measurements recorded at daily, hourly and n-minute time intervals. The data were screened for inaccurate, duplicate, and other suspect measurements. The 1-day and 1-hour data were also analyzed for any potential trends that could affect the results.

Regions with similar annual maximum series precipitation characteristics were grouped together. Adjustments were made to the groups after additional statistical tests and climatology assessments. Multiple probability distribution functions were tested on each region for each duration and the best distribution was then selected with goodness-of-fit tests.

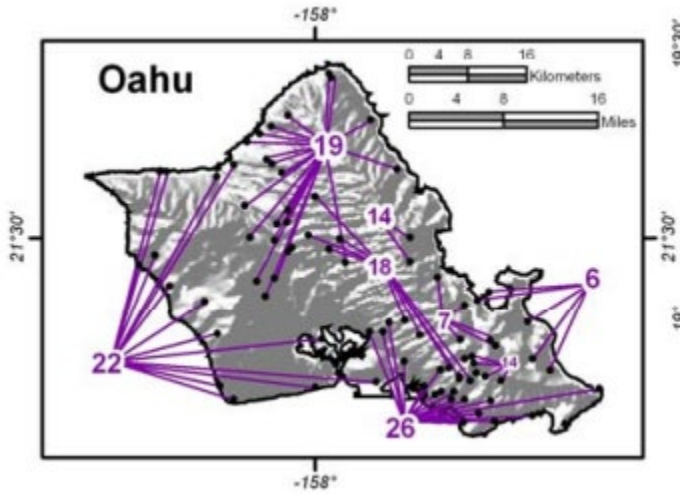

Figure 5: Atlas 14 Station Groupings (Daily)

Frequency estimates for a selected distribution were determined at each station, using a combination of site specific and regional data. A Monte-Carlo simulation (many individual samples between uncertainty bounds) was used to produce the 90% confidence intervals, which are the 5% and 95% confidence limit estimates. A relatively small number of stations have data at less than 1-hour intervals, and therefore both the precipitation frequency and confidence intervals for durations less than 1-hour were computed using scaling ratios between the n-minute and 1-hour frequency estimates.

Table 5: Scaling Factors Applied to 1-hour quantiles to produce N-minute Durations

Duration (minutes)	5	10	15	30
Scaling Factor	0.29	0.43	0.54	0.76

Gridded estimates of the frequency relationships and confidence intervals were determined from mean annual maximum grids and the regional ratios. The mean annual maximum grid for each duration was derived from specific station estimates and PRISM spatial interpolation. The confidence interval data was then derived in an iterative process using the Cascade, Residual Add-Back (CRAB) spatial interpolation procedure. The resulting grids were examined and corrected in cases where inconsistencies occurred between durations and frequencies. Additional descriptions of this process are in the Atlas 14 document.

Point Data versus Grid-based Basin Averaged Data

The Feasibility study estimated the precipitation frequency values using a basin centroid value for the Annual Maximum Series (AMS) at location North 21.3092 Latitude and West 157.8071 Longitude. The updated point values at this location are shown in the table below, pulled at the time of this report. (original values from the feasibility report are shown above.)

However, there were significant orographic effects that suggested that a point value may not accurately capture the basin wide expected rainfall frequencies. The Zonal Statistics tool in ArcGIS software was used to develop an average point precipitation value for the 0.01 AEP 24-hour frequency precipitation depths for each subbasin, which is shown below in Table 6. There is over a 7-inch variation between the far Mauka (near the mountains) and Makai (near the ocean) subbasins. The same method was used to produce 0.01 AEP 12-hour frequency precipitation depths for each subbasin, shown in Table 7. The data in these tables were used as the spatial pattern for the March 1958 and HMR39 hyetographs within the HEC-WAT model.

Table 6: Atlas 14 0.01 AEP 24-Hour Frequency AMS Precipitation for Ala Wai Watershed

M13	9.89		

For this study, the rainfall data was pulled graphically to account for the significant orographic effects in the upper portion of the basin. The gridded annual maximum series (AMS) frequency rainfall data was downloaded for the Hawaiian Islands and an ArcGIS zonal statistics tool was used to create a basin averaged mean value and basin averaged confidence intervals as shown below. For both tables the best estimate value is bolded, while the confidence intervals are in parentheses. The difference from the data used in the Feasibility Study for the 24-hour, 0.01 AEP frequency volume was approximately 1 additional inch of rainfall.

Point versus Basin Totals

Precipitation frequency estimates from the Hawaii Atlas 14 data are estimates for a point location and are not intended for direct use for areas over 10-square miles per page 17 of Atlas 14 Volume 4 Version 3. An additional step is then needed to convert to area-based duration relationships for the Ala Wai Basin, which is 16.2 square miles.

Initial estimates from the feasibility report used the TP 40 Method for depth-area reduction. The Technical Paper 40- Rainfall Frequency Atlas of the United States for Durations from 30 Minutes to 24 hours and Return Periods from 1 to 100 years was published by the Weather Bureau in 1961. This method is internal to the frequency storm methodology produced the current HEC-HMS version. However, this version, while commonly used on projects in the Hawaiian Islands, was not developed for this area. Therefore, the depth-area reduction curves developed as part of the Probable Maximum Storm documents for the Hawaiian Islands (HMR 39- Hydrometeorological Report No. 39 published by the Weather Bureau in 1963) were used. The differences between the two methods are minimal. However, the HMR 39 curve did not adequately provide data to determine sub-hourly precipitation volumes. Therefore, the Atlas 14 scaling factors referenced above were used to create sub-hourly precipitation volumes. The reduction curves for multiple TP 40 time periods and the 24-depth reduction for the HMR 39 method are shown below. Along with the HMR 39 Depth-Area reduction curve are 4 depth-area relationships from storms in the Hawaiian Islands.

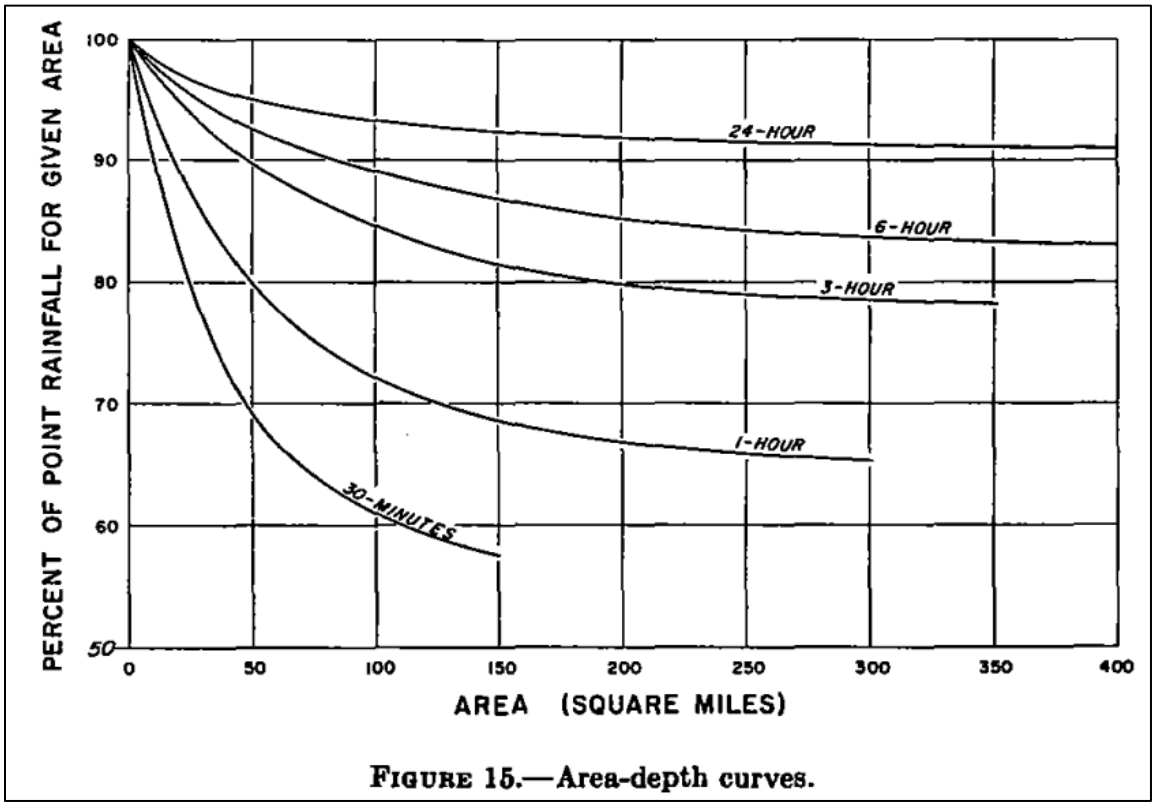

Figure 6: TP 40 Reduction (Hershfield, 1961)

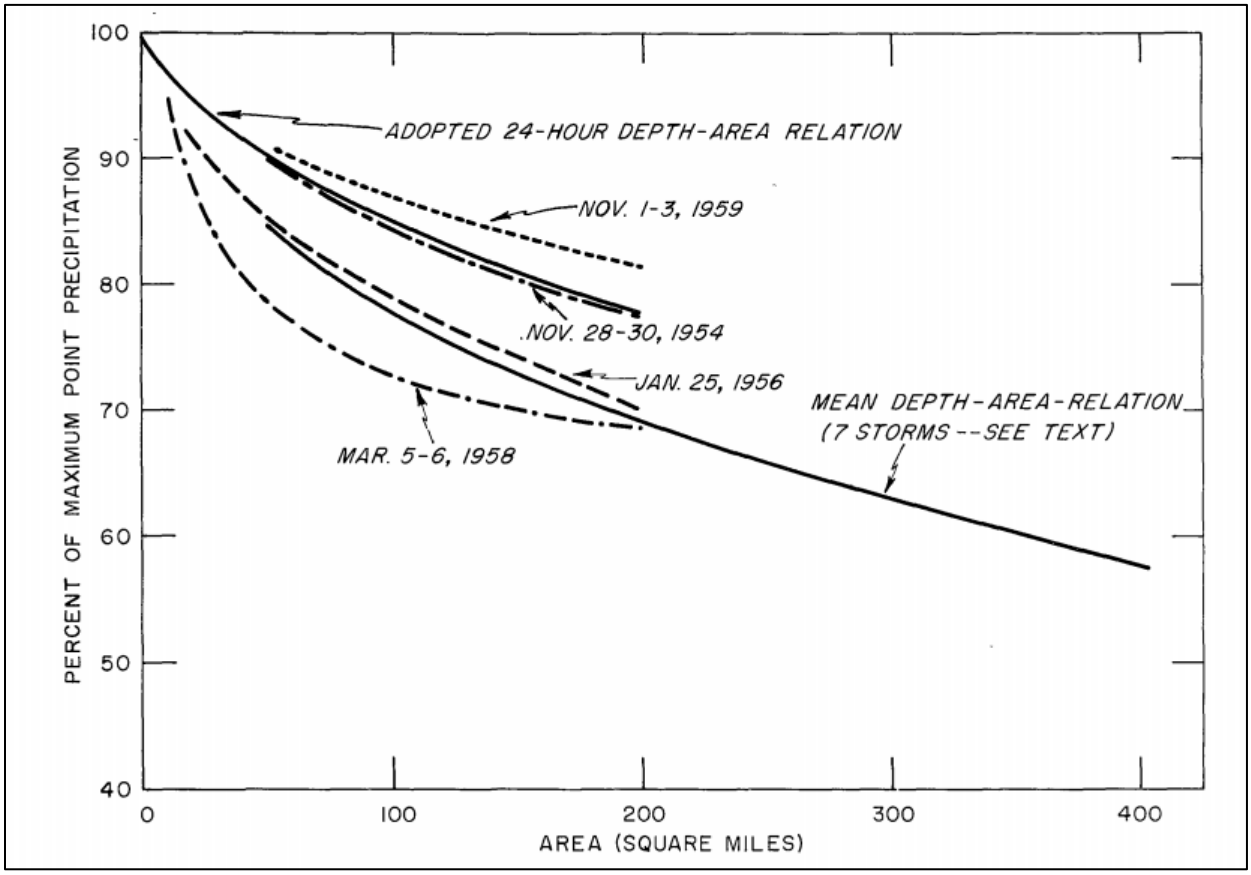

Figure 7: HMR 39 Depth Area Relationship

A significant comment to the frequency estimation process was that largest storms in recent record have been localized and not basin wide, whereas the frequency estimation is basin wide. The decision to have this assumption is slightly conservative for more frequent events but ensures that there is no discrimination among the level of protection at specific areas throughout the basin. This assumption is standard amongst all engineering-based agencies working in the area. We are in the same order of magnitude as the most recent FEMA FIS and the City and County of Honolulu's design standards for flow estimates from the Feasibility Study H&H appendix.

The 1967 event and 1958 events which occurred in the Ala Wai Basin occurred at a basin-wide level. The HMR 39 document described the 1958 event as significant Oahu-wide. "During the March 1958 storm all stations on Oahu reported 2-day totals of at least five inches. The highest officially published amount (Climatological Data) was 24.1 inches at Lunalino Home situated in southeastern Oahu in a valley just west of Koko Crater. However, there were unofficial reports of up to 26 inches. In the 3-day period March 5-7, 1958 the rainfall totals amounted to 50 to 80 percent of the total median annual precipitation along the leeward southern coastal areas of Oahu. In a kona storm like that of March 1958 the orographic effects are diminished because a more nearly uniform level of precipitation is produced from a non-orographic convergence mechanism. This relatively uniform level of precipitation is evident… a nearly 1800-foot difference in elevation does not appear to have any noticeable effect on the magnitude of the rain."

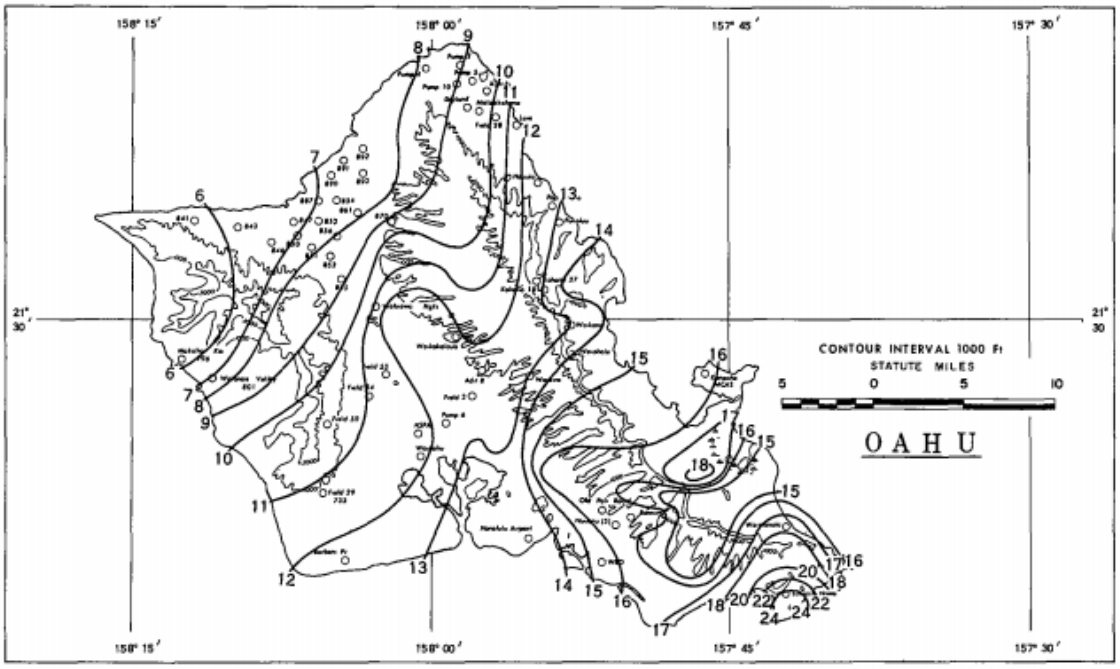

Figure 8: March 5-6, 1958 Storm- Inches of Rainfall (HMR 39)

From historical evidence along all the Hawaiian Islands orographic differences in rainfall decrease with increasing precipitation intensity. Riehl in his article "Some Aspects of Hawaiian Rainfall" emphasized that, "The larger the rainfall the greater becomes the relative homogeneity of storms. As storm intensity increases, the importance of the orography declines." (Riehl, 1949) The final precipitation frequency with a depth area reduction factor of 0.97 applied is shown in the table below. The Atlas 14 precipitation frequency values shown in Table 10 were used to develop the three parameter Generalized Extreme Value (GEV) distribution shape, scale, and location parameters that were input into the HEC-WAT hydraulic sampler.

Table 10: 12-Hour AMS Basin Average Precipitation Frequency with Depth Area Reduction

12-Hour Gridded AMS-Based precipitation frequency estimates with 90% confidence intervals (in inches)			
Return Period	AEP	12-hour	24- hour

1000	0.001	**15.72** (11.78-18.85)	**20.16** (16.42-23.96)

Basin Updates and Calibration

At the beginning of this study, a calibrated HEC-HMS model was provided. There have been only three significant events in the observed record with quality data, and these events, the 1967, 2004, and 2006, were used. The details of this effort are discussed in the Flood Risk Management Study O'ahu, Hawai'I Final Feasibility Study Report with integrated Environmental Impact Statement Appendix A- Hydrology and Engineering as well as various Oceanit Reports referenced in the Previous Modeling Efforts section above.

However, geometry and routing adjustments were necessary to better model the upstream dam drainage areas, and to better interface with the hydraulic model. Changes to the base HEC-HMS model geometry include: 1) splitting the K2 Subbasin in order to have an appropriate inflow location at the upstream of Kanaha Stream in HEC-RAS; 2) Redividing and routing the M5 and M6 Subbasins to better match actual location and flow condition for the prospective Woodlawn Dam, and later adding the effects of the local sewer system which would route flows across overland drainage boundaries and into the dam; 3) Redividing and routing the M1 and M3 Subbasins to better match actual location of the prospective Waihi Dam; 4) Splitting the routing for Reach 1 so that the flows upstream and downstream were better matched the locations for the prospective Waiakeakua and Waihi Dams, as well as better aligning the junction of the two streams; 5) Redividing and routing the K1 and K3 Subbasins to better match actual location of the prospective Makiki Dam; 6) Adjusting the RK1 routing reach to better match the handoff location from K1; and7) Routing Subbasin P5 so that it doesn't route though the prospective Waiomao Dam. The final change to the basin geometry was the removal of the reservoir system that represented the routing in the Ala Wai Canal, in order to save model runtime and as no data was found that documented the input values. For the purposes of this study, only HEC-RAS was used to route the two-dimensional behavior of the flow through the channel. A table of final subbasin names and drainage areas is provided below for model verification.

Updated Hydrologic Model Verification

Split subbasins and other basin modifications were verified against the calibrated feasibility model results at the next downstream computation point that combined all of the geometry changes for a given area. They were matched to either the flows from the provided the 1967, 2004, and 2006 calibration events, or the flows from existing feasibility frequency routing outputs. Only the Manoa-Pololo portion of the basin was available for verification for the 2006 event. Calibration verification methodology depended on when in the study the changes were made, the earliest changes were matched to the calibration and feasibility frequency data, while the later changes were verified by matching the downstream routing results of basin frequency events only (The adjustment of K1/K3, M1/M3, and the second iteration of the Woodlawn Detention inflows). The calibration verification datasets are shown below.

The model time step was also reduced from the five-minute calibration time step to a one-minute time step. Therefore, each of the below new basins were also run on a one-minute time step to ensure that there were no significant deviations from the calibrated results.

Table 13: 1967 Calibration-Subbasin Correction Data

	K2A	K2B	M6A (1st Adjustment)	M6B (1st Adjustment)
Old Area (MI^2)	0.850		0.353

For the M1/M3 Adjustment, the Routing reach RM1 was split into the two areas up and downstream of the original junction, into RM1 and Reach 1. This routing reach used the Muskingum-Cunge method and the length was simply split across the two reaches, with all other calculated parameters remaining the same. M5 originally used a routing reach RM8 to route flows using a Muskingum-Cunge method. This method was replaced by a lag of 10 minutes to route water from the bottom of the subbasin to the main stream.

For Table 18 through Table 21 and Figure 13 through Figure 16, all updated values are in the 1-minute increment, while the original values are in the 5-minute increment. The JM2 junction envelops the changes for both the M1/M3 split and the Woodlawn area changes. The JK1 junction envelops changes for both the K1/K3 split and the K2A and K2B split. These nodes were validated in HMS version 4.2.1 and there has been a small separation in results with version upgrades for the K2 and JK1 locations.

Table 18: A0.5 AEP Frequency for Locations with Basin Corrections

As part of the update to HEC-HMS version 4.3 and 4.5 an index method is now required to route Muskingum-Cunge Routing reaches. Per the recommendation of the Hydrologic Engineering Center (HEC), the "celerity" method was used with an index celerity of 5 ft/s. No adjustments to calibration were made at this point, as changes to flow calculation results were minimal.

An additional geometry was created for later use in the HEC-WAT model. This geometry was set to only calculate flows up to the HEC-RAS inflow locations for additional speed in the calculations. This version was also upgraded to HEC-HMS 4.5 due to the rapid model version updates throughout the life of this project, and compatibility with the HEC-WAT model. An image of the geometry is shown in the figure below.

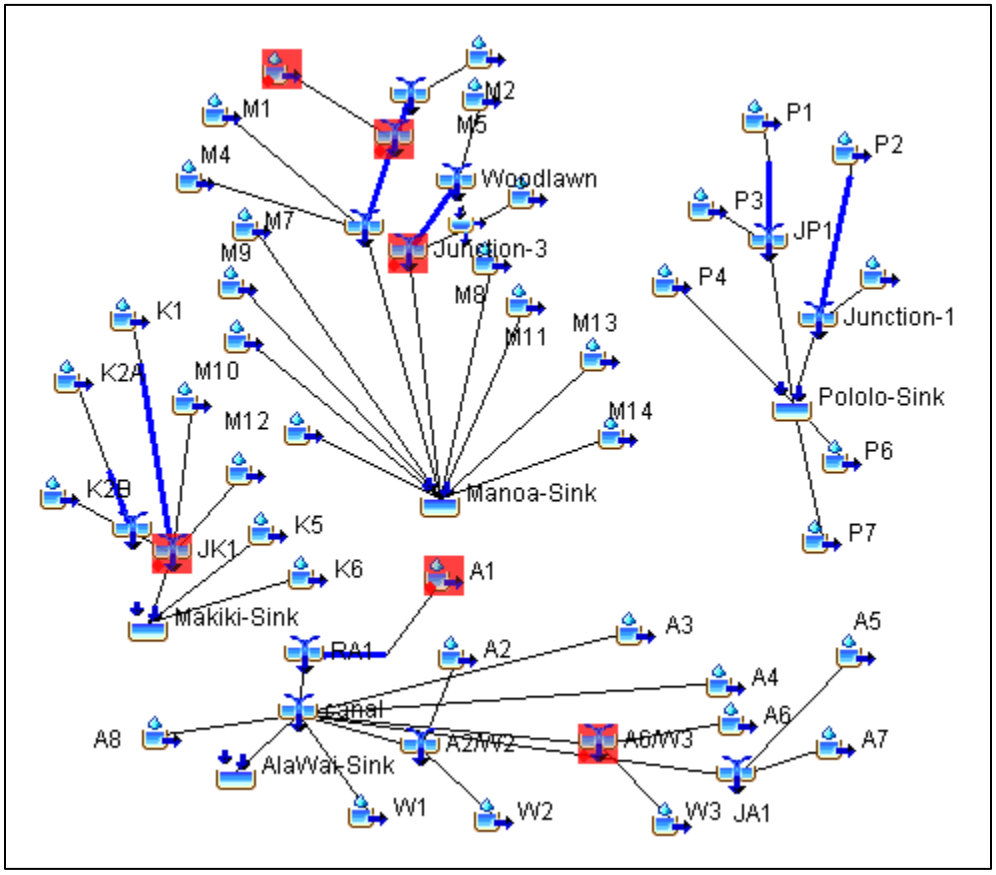

Figure 17: HMS Basin Geometry for use in the HEC-WAT environment

It was also discovered throughout the hydraulic portions of this the study that a significant amount of flow can "back up" behind bridges and in some cases escape into the overbanks. The HEC-HMS model is well calibrated to the 2004, 2006, and 1967 events. However, the ability of the model to represent these effects is questionable beyond the magnitude of these calibration events. **For large events (i.e. the 1% event) it is recommended that the HEC-RAS model be used to report stream routing near and downstream of constrictions, this includes the majority of the routing in the main streams and the Ala Wai Canal.**

Coincident Design Efforts/Detention Basins

Dam Design Information- Iterative Simulations

Two teams, one based in the Seattle District and one based in the New Orleans District were leads in the design process for the dams and pumps, respectively. Multiple variations of the dam culvert, spillway, and storage were modeled in an effort to better understand the system response for each of the upstream dams. Initial excavation, spillway, and dam data for each iteration was provided by the Seattle Design Team. The storage-elevation relationship post-excavation was pulled in the HEC-RAS version 5.05 Mapper and merged with updated LiDAR provided by the Hawaii District. Reasonable culvert elevations and lengths were estimated from this terrain. A reasonable land area over encompassing a given possible pool was analyzed to determine a unique Elevation-Volume curve, as shown below. The same

method with no excavation (LiDAR only) was used to determine a “no excavation” storage curve for each detention basin. Please note that each of these curve calculations assumed a level pool.

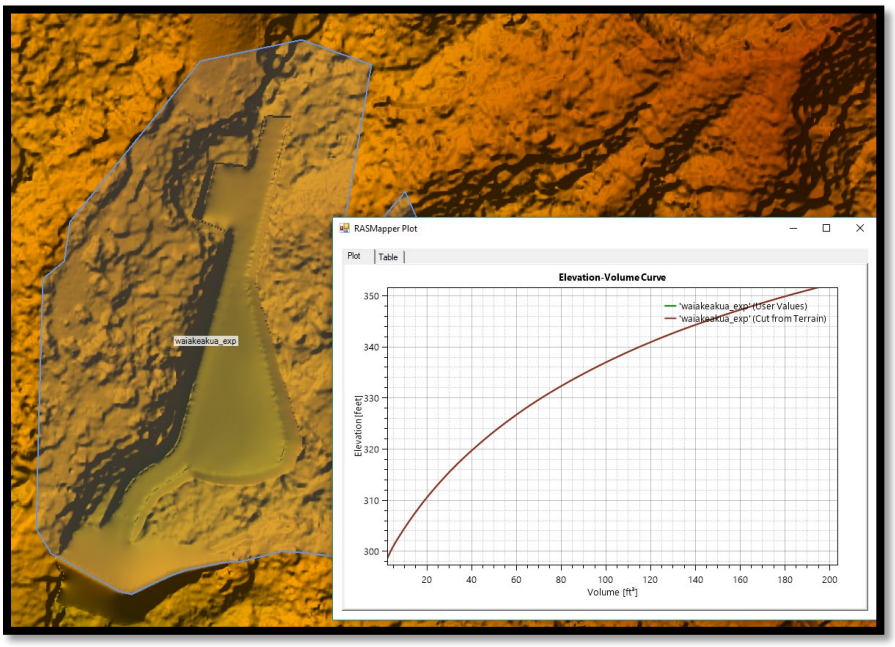

Figure 18: The Third Iteration of Waiakeakua Dam

Makiki, Waihi, Waikeakua, Pukele, and Waiomao detention basins were designed for both debris and detention and were located in the upstream reaches of the system. Each basin was required to pass the design event without debris blocking the intake structure. Woodlawn Dam was designed for only detention and originally had no excavation. Kanewai, Hausten Ditch, the Golf Course diversions, and other lower basin proposed structures were being managed from the Hawaii and New Orleans Districts. These structures are modeled in the Hydraulic Model, HEC-RAS.

After each design iteration the data was incorporated into a series of HEC-HMS simulations (With Project for the 1, 2, 5, 10, 20, 50, 100, 200, and 500 year or 1, 0.5, 0.2, 0.1, 0.05, 0.02, 0.01, 0.005, and 0.002 AEP NOAA 14 based feasibility study precipitation frequency events) to determine the effect of the iterative changes to the overall basin. Data was reported and compared downstream of each Detention Basin. This data was provided to the HEC-RAS modeler for further analysis.

The structures on Makiki and Pololo portions of the watershed were determined to be ineffective due to the limited storage capacity that could be reasonably excavated and were removed from the study. As is discussed in the Ala Wai Canal Hydraulics Report, significant attenuation behind downstream bridges on the Manoa Portion of the watershed negated the effects of the reduced peak flow. Woodlawn detention also did not have adequate storage capacity. These structures were also removed from the study.

A final detention basin routing for the Waihi and Waikeakua basins was completed each of the 8 frequencies (0.5 to 0.002 AEP) for reporting and inclusion into the HEC-RAS model. This routing was based on the feasibility TSP with a reasonable excavation and updated WAT calculated inflows. These

excavated terrains were provided by the Seattle district. Results from this routing are added to the appendix.

Table 22: Detention Basin Properties

Dam Name	Waihi	Waikeakua
Outlet

Frequency Routings

The Atlas 14 Rainfall Frequency data is routed through a hydrologic model (HEC-HMS) to translate the rainfall to streamflow. The data was then provided to a hydraulic model (HEC-RAS) to determine the flood extent, as well as any more complex routings due to backwater or overland flow.

The frequency routings were completed in two ways. First, a simple direct input of the feasibility precipitation data into the updated HMS model was created and provided to the HEC-RAS model. This data was used to compare the feasibility study and the results of this effort.

Secondly, a Monte-Carlo water analysis tool, HEC-WAT, was built to sample and iteratively compute frequency discharges with uncertainty. This data was then processed in HEC-SSP for the final project frequency flow hydrographs. The HEC-HMS output locations needed for input into the HEC-RAS model for either method are shown below. The part B column in the below figure is the HMS output location, while the Boundary Condition column indicates the RAS inflow location.

Figure 19: HEC-RAS Boundary Inflow Locations

Feasibility Comparison (Basin Averaged)

The feasibility study Atlas 14 best-estimate annual maximum series precipitation was incorporated into a series of HEC-HMS simulations to determine the effect of the additional incremental precipitation

volume to the overall basin. The precipitation data was input into the HEC-HMS frequency storm meteorologic model. Please note that within the meteorologic model, the point data was converted to an area value using the TP40 Area Reduction Method. This is inherent to the code within HEC-HMS and is recommended as an acceptable alternative in the Atlas 14 report.

Table 24: HEC-HMS Metrologic Model Input Data (in inches)

The frequency storm was then routed through the updated basin, which is shown in the graphic in Figure 11: Updated HEC-HMS Schematic. As described earlier, a significant amount of flow can “back up” behind bridges and in some cases escape into the overbanks. The HEC-HMS model is well calibrated to the 2004, 2006, and 1967 events. However, the ability of the model to represent these effects is questionable beyond the magnitude of these calibration events. For large events (i.e. the 1% event) it is recommended that the HEC-RAS model be used to report the two-dimensional effects of stream routing near and downstream of constrictions, as well as though the entirety of the Ala Wai Canal.

The peak discharge values in cfs from these feasibility comparison routings are shown in the tables below. This is the standard method for frequency routing of small basins. However, due to the orthographic impacts and upper basin constrictions that have significant impacts to routing frequency, as well as the high level of risk to this project, alternative precipitation inputs (graphical zonal statistics for precipitation volumes and the HEC-WAT method for routing) were continued for use in risk analyses in this study.

HEC-WAT

In order to improve upon the estimated values for the spatially varied simulations and uncertainty ranges, a stochastic approach was recommended by advisors. Hydrologic Engineering Center – Watershed Analysis Tool (HEC-WAT) is a software that uses a stochastic approach compute the meteorologic, hydrologic, hydraulic, consequences, and planning calculations needed in various analyses and design processes. HEC-WAT integrates existing hydraulic and hydrologic software and uses a Flood Risk Analysis (FRA) Compute to run Monte Carlo-style uncertainty sampling to better evaluate an uncertainty range across various parameters throughout the watershed. This is a first-generation software, published in 2017.

"HEC-WAT distinguishes between and separates sampling of natural variability (aleatory uncertainty) from knowledge uncertainty (epistemic uncertainty) using a nested Monte Carlo sampling structure with inner and outer loops. Natural variability is sampled at an event level (inner loop), while knowledge uncertainty is sampled at a realization level (outer loop); where a realization contains enough flood events to fully characterize the natural variability. A realization contains many HEC-WAT "analysis periods" or lifecycles, with an event placed in each year of a lifecycle. At the event level, the Hydrologic Sampler generates each flow or precipitation event using a random instance of natural variability, such as peak flow or total precipitation magnitude and date. The primary knowledge uncertainty captured in the Hydraulic Sampler is in the annual maximum flow or precipitation frequency curves. The uncertainty is defined by an equivalent record length, N and at the realization level, N is randomized by re-estimating each frequency/ curve from an N-year bootstrap. Since each realization is based on one random instance of knowledge uncertainty, many realizations are required to capture the full distribution of possible outcomes." (CEIWR-HEC, 2018)

Simply, the WAT is a tool that links models and samples uncertainty values for each iterative model run. An example would be selecting a precipitation volume between uncertainty bands, a precipitation spatial pattern, and a loss rate in each subbasin making a run and doing it over and over. Then combining all the results into frequency outputs.

For the purposes of this study, spatial and temporal rainfall uncertainty and the SCS loss coefficient were the only uncertainty parameters evaluated, due to the limited data available for other parameter ranges. The HEC-WAT was used to integrate the hydrologic sampler (used to create precipitation patterns) and the HEC-HMS model and make stochastic simulations. A duration analysis plugin developed by Will Lehman was integrated into this modeling effort with the assistance of Evan Heisman. This allowed an output relationship between depth and frequency for each specified parameter. Post processing in Hydrologic Engineering Center – Statistical Software Package (HEC-SSP) created a balanced hydrograph output used for input into HEC-RAS.

Please note that HEC-RAS stochastic simulations are computationally intensive and were not computed in the HEC-WAT environment due to time and computational constraints.

Spatial and temporal precipitation parameters are calculated via the HEC-WAT Hydrologic Sampler. This sampler is a plug-in that creates these parameters for use in the Flood Risk Analysis (FRA) compute for the watershed response. The sampler has three hydrologic sampling methods: two based on frequency curves (flow and precipitation) and one that bootstraps historical and synthetic events. The precipitation

method was used in this study. This method uses historical temporal and spatial patterns (sample rain events) and a total event precipitation frequency curve to create the necessary input by:

1. "randomly samples an annual maximum precipitation depth from an aggregated basin average depth-duration frequency curve
2. Randomly selects a shape set
3. Disaggregates the basin average precipitation depth among the subbasin locations based on subbasin area and shape set depth
4. Scales every hyetograph in the shape set to the subbasin depth, and
5. Places the scaled hyetographs on a peak date randomly sampled from the flood season distribution" (CEIWR-HEC, 2018)

Hydraulic Sampler

To create the basin averaged depth-duration frequency curve, the three parameter Generalized Extreme Value (GEV) distribution was fit to both the published Atlas 14 12- and 24-hour annual maximum series precipitation frequency best estimate curves with an applied HMR 39 depth area reduction factor. The areal reduced Atlas 14 best estimate precipitation frequency estimates can be found in Table 10. Research of the Atlas 14 publication documentation determined that the associated gage record length for daily records was 310 years. A test in the reduction of this value revealed that there were not significantly different output data within a 50-year reduction in period of record. The input data is shown in the figure below. An approximation of the fit was created using a spreadsheet tool, then validated within the HEC-WAT hydraulic sampler. The spreadsheet tool estimated the three parameter GEV distribution based on the NOAA Atlas14 best estimate precipitation depths for 8 quantiles and computed the mean square error for each quantile until the average root mean square error (RMSE) is near zero. For the 12-hour Atlas14 precipitation frequency curve, the computed GEV parameters RMSE was 0.008 and 0.018 for the 24-hour duration. The GEV distribution parameters are Location ϵ = 3.2563, Scale α=1.4044, and Shape κ=-0.0695 for the 12-hour duration, and Location ϵ = 3.9212, Scale α=1.7585, and Shape κ=-0.0797 for the 24-hour duration.

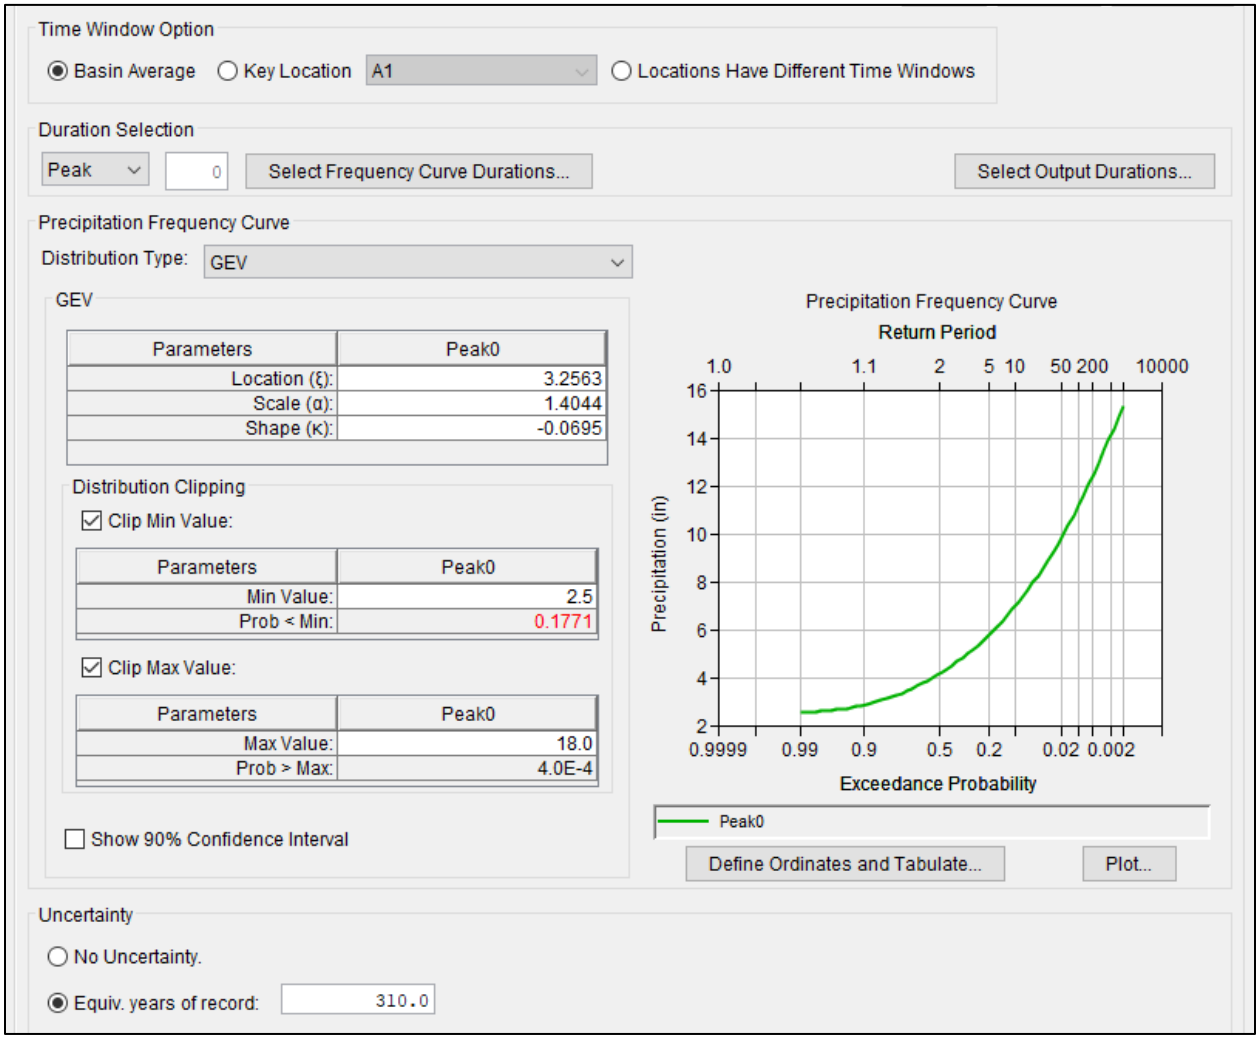

Figure 20: Hydraulic Sampler Basin Averaged Precipitation Inputs for the 12-hour Duration

A shape set refers to data depicting the historic or template storm events at the subbasin level. For this model shape sets were created for the 31 March 2006, 30 October 2004, 16 December 1967, 5-6 March 1958 events, and an HMR 39 synthetic event. The 2004 event was limited to the lower frequencies due to the large precipitation gradient. (A large amount of rain in the upper basin, and almost no rain in the lower basin: scaling is performed by multiplication and the "0" inches of rain at the coastline could not scale up which forced an unreasonably high precipitation volume in the upper basin.) The subbasin hyetographs were pulled from the calibrated events provided in the HEC-HMS by the Hawaii district. The 2006 event data was recreated for the Makiki reach using the gage patterns used in the other calibration events. The remaining data for the 2006, the entire 2004, and entire 1967 precipitation data was taken from the calibrated HEC-HMS reported subbasin precipitation results.

The 1958 shape set was created by taking the published rainfall mass curve found in HMR39 for the March 1958 temporal pattern (Figure 22). The cumulative mass curve was converted to a hyetograph, shown in Figure 23. The temporal pattern was with the spatially varied precipitation pattern from the

gridded 12-hour 0.01 AEP AMS Atlas 14 dataset shown in Table 7. The time step for the output hyetographs was 5-minutes.

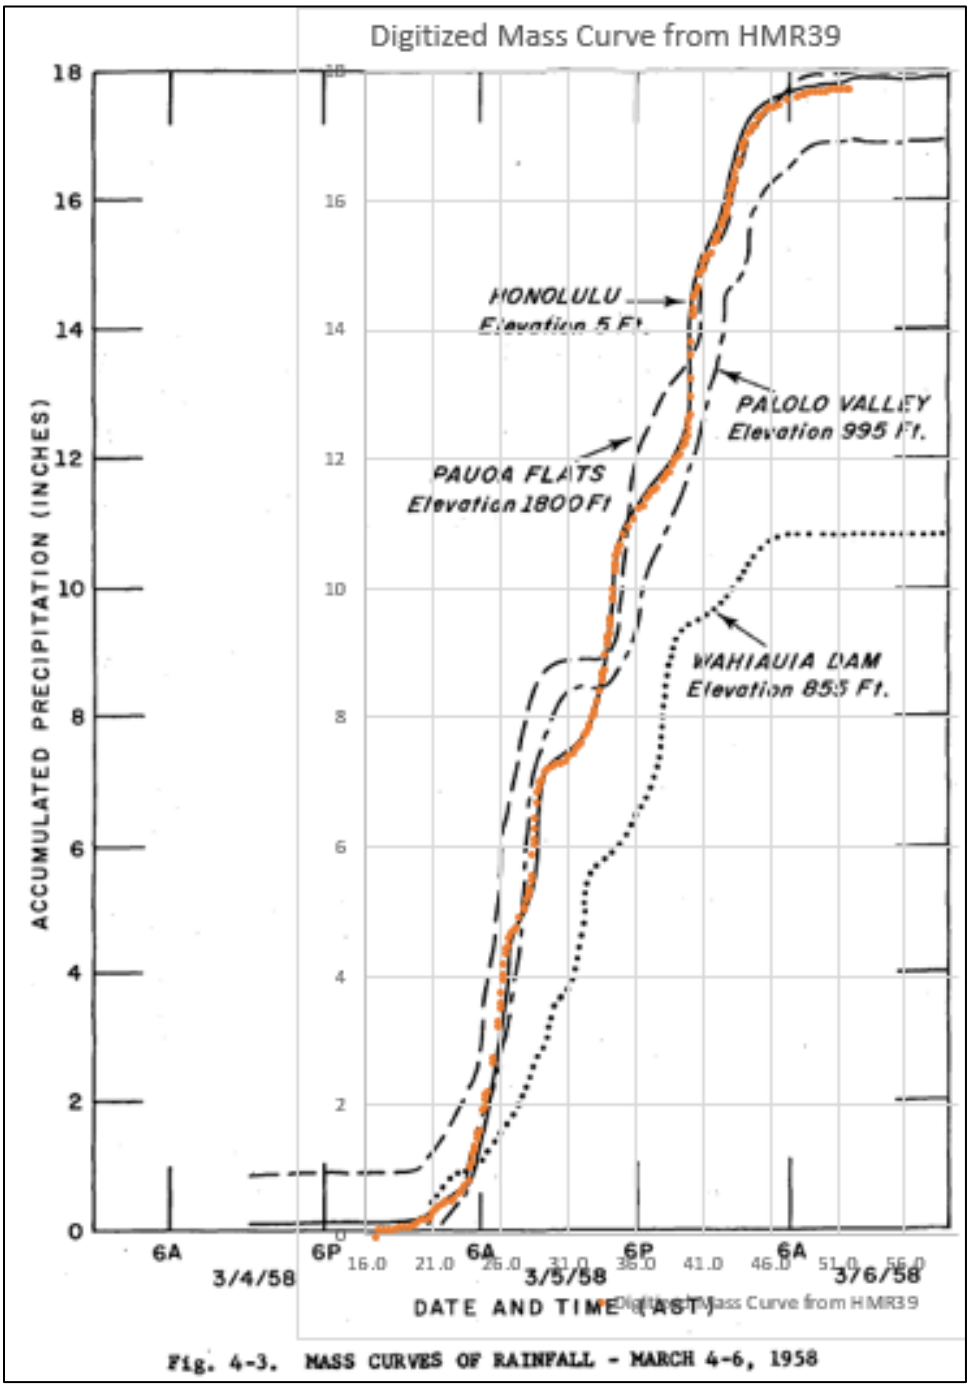

Figure 21. Digitized March 4-6, 1958 Precipitation Mass Curve from HMR39

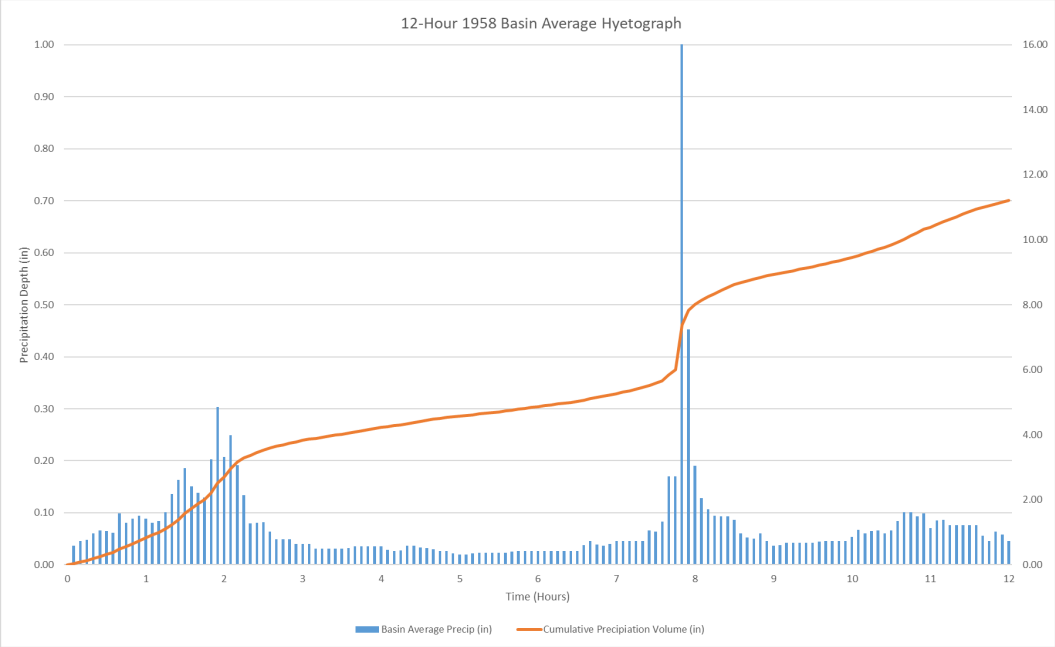

Figure 22. 12-Hour 1958 Basin Average Hyetograph

The HMR 39 shape set was created by applying HMR39 Temporal Pattern B, shown below in Figure 24, to the 12-hour AMS 0.01 AEP spatially varied precipitation pattern shown in Table 7. The time step for the output hyetographs was 5-minutes.

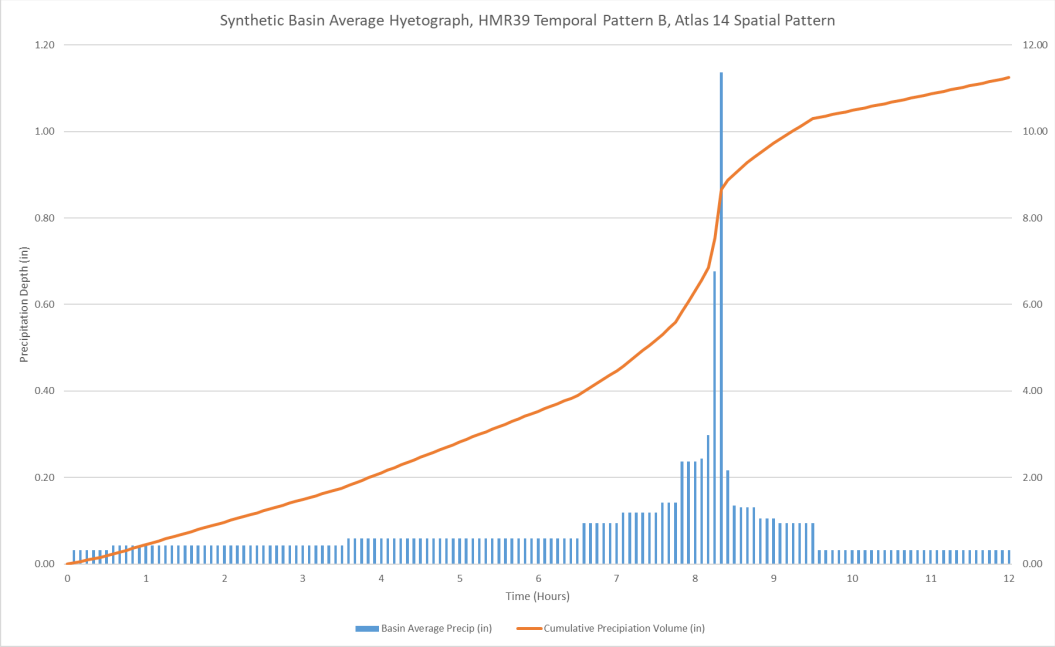

Figure 23. Synthetic Hyetograph Shape: HMR39 Temporal Pattern B, Atlas 14 Spatial Pattern

Tabular data displaying the subbasin hyetographs for all five shape sets are included in the data appendix of this report. A sample image of each of the sample storms sets are shown in Figure 25

through Figure 29. Please note that the precipitation pattern for the 2004, 2006, and 1967 events are based off of multiple gage datasets, and the precipitation patterns will vary somewhat from subbasin to subbasin.

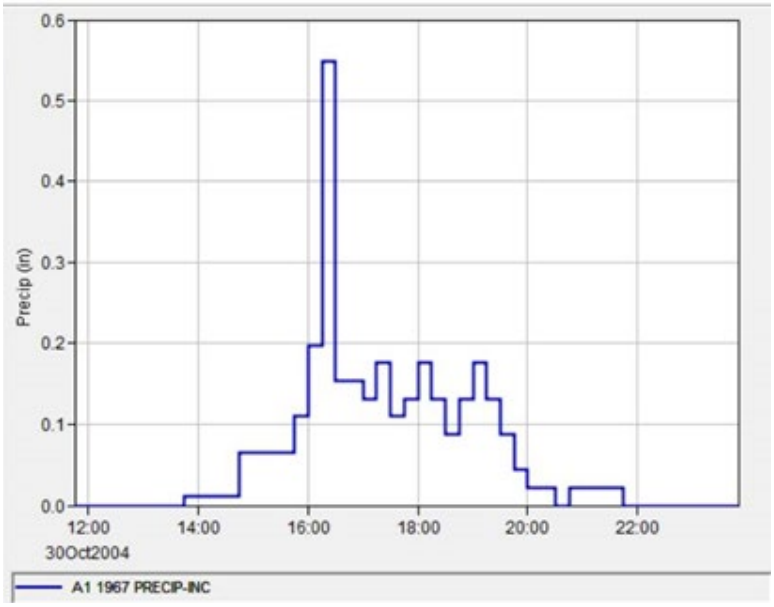

Figure 24. 1967 Storm Pattern Sample Hyetograph for the 12-hour duration for the A1 Subbasin

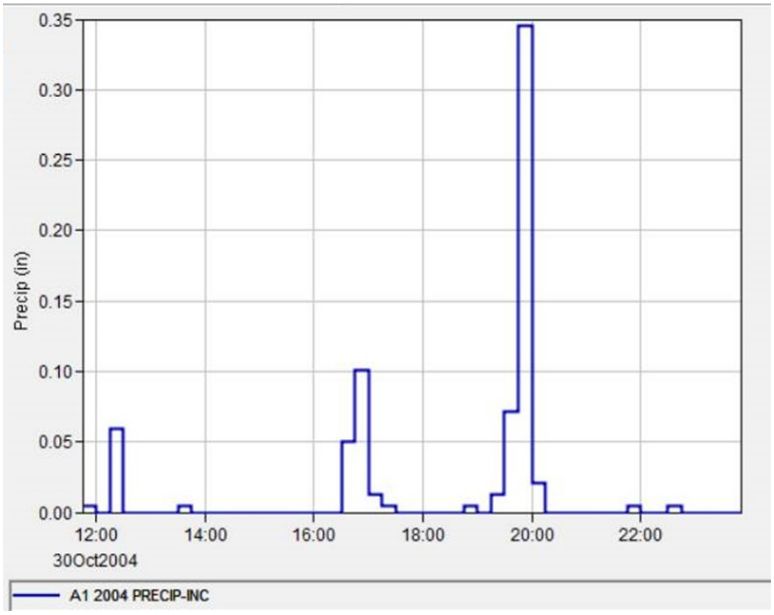

Figure 25. 2004 Storm Pattern Sample Hyetograph for the 12-hour duration for the A1 Subbasin

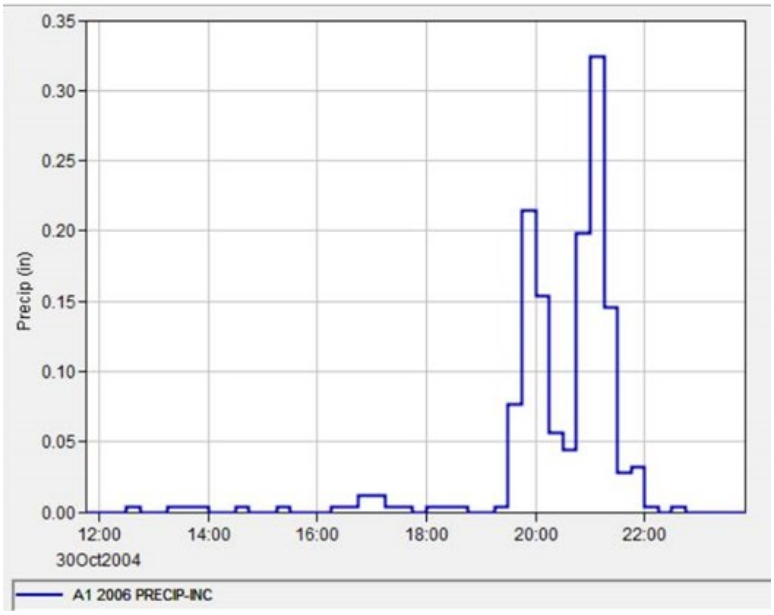

Figure 26. 2006 Storm Pattern Sample Hyetograph for the 12-hour duration for the A1 Subbasin

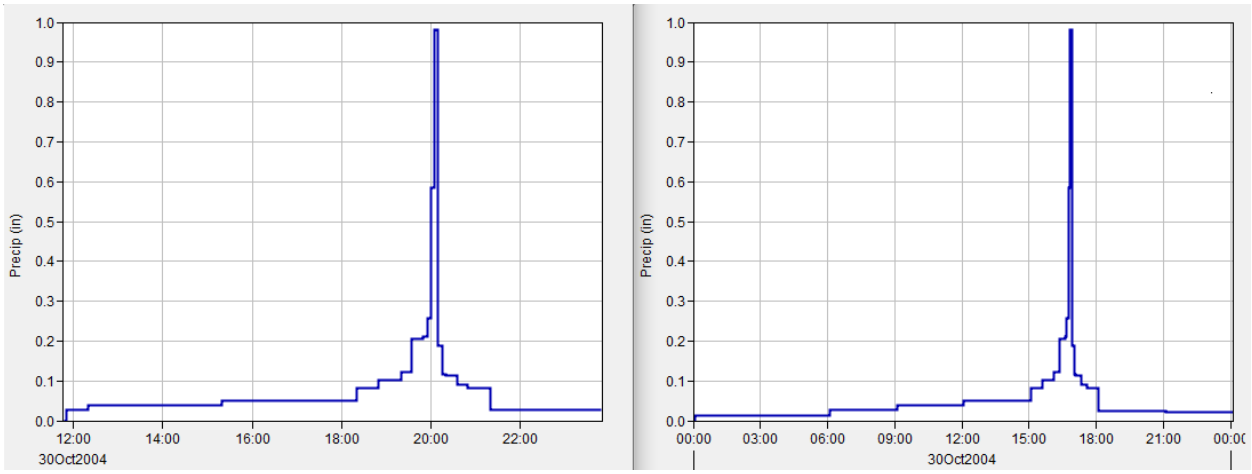

Figure 27: HMR39 Storm Pattern Sample Hyetographs for the 12- and 24-hour duration for the A1 Subbasin

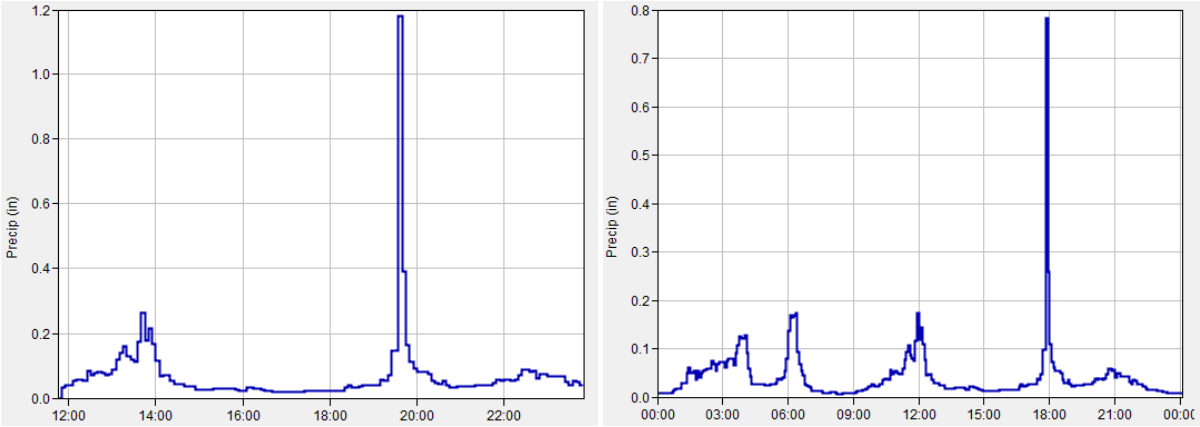

Figure 28: 1958 Sample Hyetographs for the 12- and 24- Hour duration for the 1958 Storm for the A1 Subbasin

For this scenario there are no distinct seasonal response distribution differences and the flood season distribution is set to an even distribution throughout the year. The algorithm then randomly picks a storm pattern from the five events and scales it to a randomly selected volume. This process is then repeated for every model iteration.

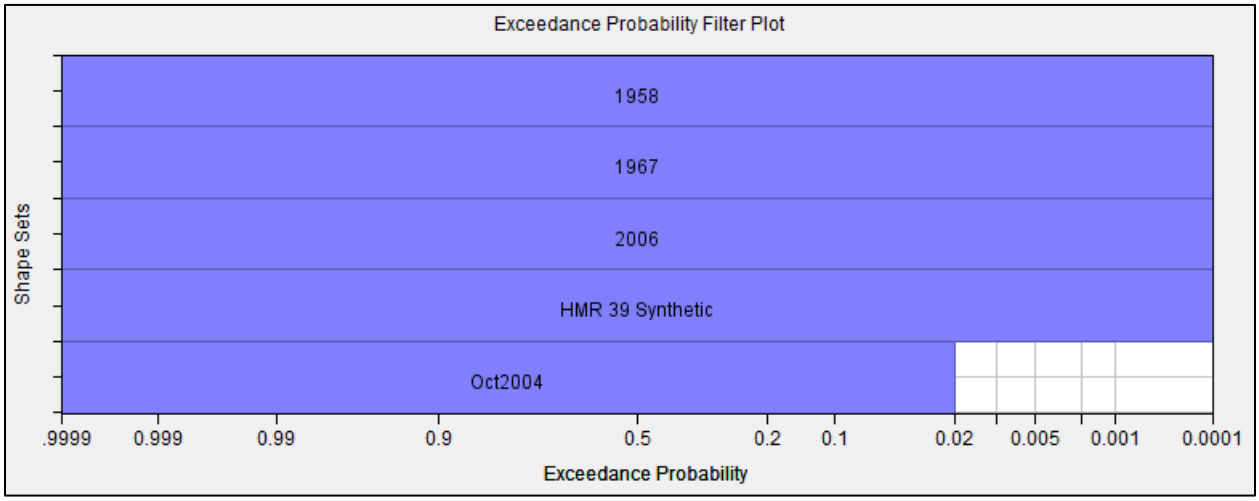

Figure 29: Sample Storm Representation

12-hour vs 24-hour

High-Intensity rainfall on steep slopes of the 16.2 square mile drainage basin can produce very flashy flood events. Time to peak is typically less than 1 hour, and even with large storms, the rise and recession of the flood hydrograph typically occurs within 6 hours. As shown in a sample shape set series for the M12 subbasin precipitation, below, it is also typical for the total event precipitation to fall for a relatively short time period. The figures below show the pattern for the 2006, 1967, and 2004 events from left to right, standardized to the peak 24-hour precipitation dates for the 2004 event. This is currently necessary for the HEC-WAT Hydraulic Sampler to compute. For this example, the significant precipitation totals occur within 3 hours,

8 hours, and 9 hours respectively. These precipitation patterns are replicated for each subbasin within the basin.

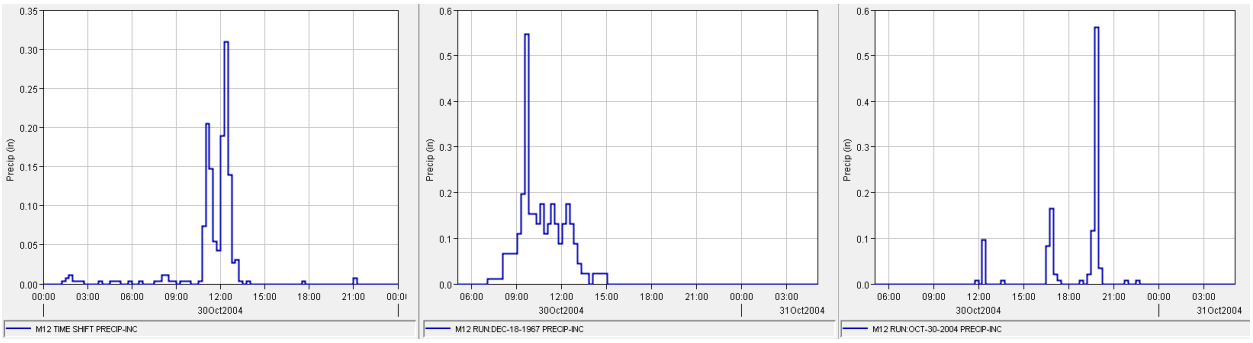

Figure 30: Hyetograph Templates

One drawback to the HEC-WAT methodology as described, is that when required to use the 24-hour volume, the total volume is placed at these patterns shown above. This artificially peaks the 24-hour volumes into the 3-, 8-, and 9-hour bands. To account for critical precipitation and flood response time, a 12-hour storm was produced as the primary frequency dataset, with a 24-hour volume produced as a sensitivity. The 0.01 AEP frequency peak flows for the 12-hour dataset were computed to be roughly equal to the 0.017 to 0.029 AEP 24-hour volume frequency.

HEC-HMS

The HEC-HMS model developed for the Atlas 14 frequency simulations was imported into the HEC-WAT. This was the basin that was stripped of most of the routing reaches to facilitate faster compute times. The HEC-WAT software was upgraded from HEC-HMS 4.3 to 4.5 for WAT versioning compatibility. The HEC-WAT also requires a specified hyetograph meteorologic model to be selected for the base uncertainty analyses in HEC-HMS. However, the hyetographs connected to the HMS uncertainty analyses were not used in the final simulations, as the Hydraulic Sampler will recreate this input for each iterative compute.

Loss Uncertainty

Uncertainty is a required component in the discharge calculations per EM1110-2-1619 and ER 1105-2-101. Uncertainty for the rainfall volume was computed using the estimated record length in the hydrologic sampler. To include uncertainty in the rainfall-runoff routing, a range of loss parameters was calculated.

The WAT currently requires an uncertainty compute method within HEC-HMS. An uncertainty run requires at least one parameter sampling a range of values instead of a single calibrated value. For the HEC-HMS uncertainty compute each individual loss parameter was sampled 20 times per single iterative HEC-WAT run.

To determine the loss value for each subbasin, the table 4-3 “Calculation of Composite Curve Numbers for Ala Wai Watershed” was taken from the feasibility report. This table listed the percentages by area of soil type and land use for each subbasin. These values were assigned a curve number associated to a loss value using the TR55 dataset. Uncertainty in the rainfall runoff was estimated though varying those

loss rates (rates were set to randomly sample between values associated with a range of land uses one band higher and one band lower than the reported field values. (i.e. moderate to highly urbanized, or various levels of plant cover in a forested region). The original, upper and lower loss category values for each soil type and land use in the Ala Wai basin are shown in the tables below.

Table 29: Variation of the SCS Loss Parameter for each Land Use Type

Feasibility Report Category Land Use	Soil Type			TR55 Category for Land Use
	A	B	C	
Original Land Use CN Estimates				
Bare Land	72	82	87	dirt
Evergreen Forest	30	55	70	woods-good condition
Grassland	39	61	74	open space- good cover/good quality forage-grazing

Kinematic routing was used in this HEC-HMS model for the highly urbanized portions of the Ala Wai Basin. The loss parameters were split across two flow planes, with the two flow planes averaging by area to equal the overall subbasin loss rate calculated by soil types and land use. Plane 2 is used to model the very urbanized-impervious areas with a CN of 98. The plane 1 loss values vary from 69 to 86 for the original values. Therefore, only the first plane was varied in the uncertainty calculations. The plane 1 loss values were varied so that the area average of the two planes equal the SCS curve number range described in Table 31.

Table 31: Flow Plane SCS Loss Value Uncertainty Range

HEC-WAT Duration Plugin

The HEC-WAT Duration Plugin is a script that reads and outputs volumes for either precipitation or flow at specified calculation points for a specified duration. While the plugin is integrated into the HEC-WAT model, there is no interface and text editing is necessary to produce results. For this effort flow output at the locations that are input into HEC-RAS were calculated to get the appropriate volumes to complete a balanced hydrograph run. This data will be then post-processed by HEC-SSP to create those inputs. A sample of the code to get the data location and pull output is shown below. The Duration Max that is being output is the maximum averaged duration in hours. The peak value is not specified in the code but is automatically output by HEC-WAT at the time step interval. (The peak is a 1-minute maximum calculated value.) Due to the current limitations of the system the time increments between the 1-minute and 1-hour intervals are interpolated.

Figure 31: Duration Plugin-Code Sample

Iterative Routings

Once the HEC-HMS basin and simulation data are incorporated into the HEC-WAT, an alternative was created that incorporated the HMS model and Duration Plugin tool. This links the model computes to each other. A program order was set to order the compute starting with the HMS model, then the duration plugin. The Model Linking Editor was then used to link the specific data streams needed to compute the HMS model and duration editor. These connections are shown in the table below. The Output Variable Editor was used to specify the data that the Hydraulic Sampler, HMS model, and Duration Sampler would save to the DSS file. Due to the large amounts of data created with each iterative compute, stored data must be specified to limit total file sizes. This is also the location that is used to specify if an output frequency curve should be computed. The output dataset is shown in the table below. Note that to limit file sizes, only a sample of the Hydraulic Sampler output locations were saved. These were used for data verification.

A time window analysis period is used to set the time period that each realization within the FRA compute uses, and how the data is reset and saved. The length of time specified in the time window needs to be divisible by the realization length but does not specify the number of iterations of the overall compute.

The minimum number of sampled events within each realization should be a minimum of approximately 2-3 times the maximum frequency analyzed. For this effort 500 events were sampled per each 120 realizations. Therefore, the 12-hour output data is considered to have adequate simulations for up to and beyond the 0.002 AEP frequencies. (CEIWR-HEC, 2017)

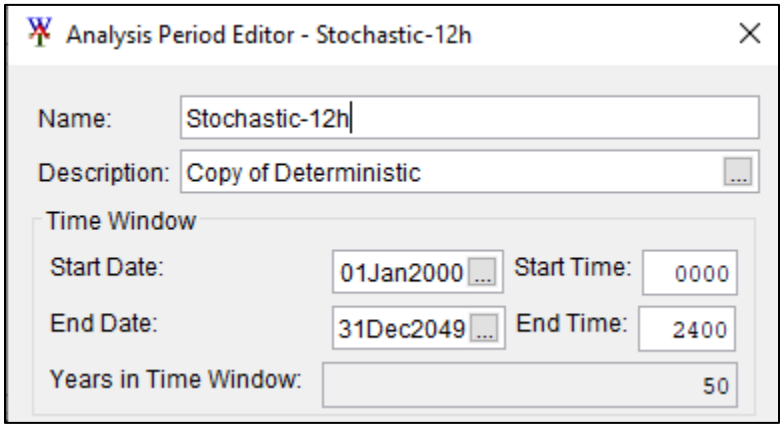

Figure 32: Analysis Period for each Realization

The Simulation Editor was used to link the Model Alternative, Analysis Period, and Program Order. Together this combines all the data sets and linkages discussed above. In the 12-hour simulation, a 500-events is set, and 120 total realizations were computed, which determines at total of 60,000 iterative simulations for each of the three models loaded into the HEC-WAT. (Hydraulic Sampler, HEC-HMS, and the Duration Plugin) In the 24-hour sensitivity simulation, 500 events were computed for 10 iterations for a total of 5,000 iterative runs. Each of the simulations is analyzed for peak flow and all other along with all durations that were specified to be output in the duration plugin. These 60,000 values (or 5,000 for the 24-hour duration sensitivity) for each time period and each location are analyzed as an annual maximum event, in order to determine individual frequency curves for that specific location and duration.

Run FRA Simulation - TEST-Duration

Compute Information for Simulation TEST-Duration

Time Window Information

Start Time: 01Jan2000 0000
End Time: 31Dec2499 2400

Simulation will not stop on errors.
Simulation will save all results.
Simulation will recompute all models.

HEC-WAT Results

After a final compute, reported data was used to validate the results. Output data in the HEC-WAT includes frequency curves with confidence intervals based on peak data values for each compute location, either for flow or precipitation. The module also outputs the basin averaged storm total precipitation as it was recreated. A comparison of the input and output for total event precipitation frequency data is shown below for the 12-hour and 24-hour duration WAT compute.

The HEC-WAT basin-average precipitation results for the 12-hour storm sampled between -0.1 to 0.3 inches different for each frequency with an average of 0.08 inches higher than the WAT input data. Due to WAT input methods the input values were 0.01 to 0.36 higher, with an average of 0.28 inches higher than the graphical AMS Atlas 14 data. The graphical data is between -0.35 to 0.36 inches different, with an average of 0.13 inches different from the original feasibility data. This difference is due to an update to the published dataset and the orographic effects bringing up basin averages. Overall, the final differences in basin-wide precipitation differences range from 0.09 to 0.78 inches from the feasibility study, with an average difference of 0.49 inches. This transition from point to graphical methods of data collection represents the most significant increase in total volume of rainfall in the basin.

The HEC-WAT basin-average precipitation results for the 24-hour storm sampled between -0.04 to 0.4 inches different for each frequency with an average of 0.23 inches higher than the WAT input data. Due to WAT input methods the input values were 0.18 to 0.74 higher, with an average of 0.59 inches higher than the graphical AMS Atlas 14 data. The graphical data is between -0.42 to 0.45 inches different, with an average of 0.17 inches different from the original feasibility data. This difference is due to an update to the published dataset and the orographic effects bringing up basin averages. Overall, the final differences in basin-wide precipitation differences range from 0.56 to 1.4 inches from the feasibility study, with an average difference of 0.98 inches. This transition from point to graphical methods of data collection represents the most significant increase in total volume of rainfall in the basin. An additional increase in scaling of storms for the less frequent events in the HEC-WAT environment.

With the addition of the duration plugin a frequency curve for each requested volume (Peak, 1-, 2-, 4-, 8-, 10-, 12-, 16-, 20-, and 24-hour durations) for each compute point was outputted as well. Each individual hydrograph for each location for each iteration is also saved to the DSS files. However, there is no composite or final output frequency hydrograph for each location created within this early version of HEC-WAT. (See below on post processing in HEC-SSP). A sample peak flow frequency curve for the combined outflow for subbasin A1 is shown below, as well as the basin averaged Atlas 14 peak flow frequencies for both the 12- and 24-hour storms in Table 35 and Table 36. A table is also included to show a peak flow comparison between the inputs from the updated frequency data reproduced as part of this study and the WAT output. Additional WAT output for additional frequencies are in Appendix A. The most significant changes to the peak flow, in addition to the precipitation as previously discussed are the rainfall temporal shapes as informed by the storms on the island, the spatial shapes which better describe orographic effects, and uncertainty in the loss calculations.

The equivalent peak flow for the 0.01 AEP 12-hour frequency event ranged between a 0.017 to 0.029 AEP 24-hour frequency event. This is due to the short nature of the storm patterns in the basin forcing the 24-hour volume into a smaller time patten, and artificially increasing peak values.

HEC-SSP Balanced Hydrographs

A balanced hydrograph analysis was performed for each HEC-RAS inflow location. The balanced hydrographs were only computed for the 12-hour duration frequency storm series using the following steps. This process is needed because, while the HEC-WAT has many storm routings and output data, they are each individually using a temporal pattern from different storm events and need to be simplified to a single neutral pattern.

1. A sample hydrograph from the feasibility study Atlas 14 0.01 AEP frequency run was input into the HEC-SSP as a Flow Data Set to ensure that peak inflows occurred at an accurate time for each inflow hydrograph location.
2. The durations were input from the duration plugin specified values (Peak [1 minute], 1-hour, 2-hour, 4-hour, 8-hour, 10-hour and 12-hour for the 12-hour duration event). The 2, 5, 10, 20, 50, 100, 200, and 500-year return intervals or 0.5, 0.2, 0.1, 0.05, 0.02, 0.01, 0.005, and 0.002 AEP frequencies were specified in this effort.
3. The template hydrograph is “balanced”, so the flow volume and frequency relationships were met for each of the flow volumes reported by the duration plugin, while preserving the peak runoff timing.
4. The data is now ready for ingestion into the HEC-RAS model for final routing with all backwater effects, overland flow, and other more complex flow schema.
5. An additional set of this calculation series was done for this step with the uncertainty limits for the 0.01 AEP event.

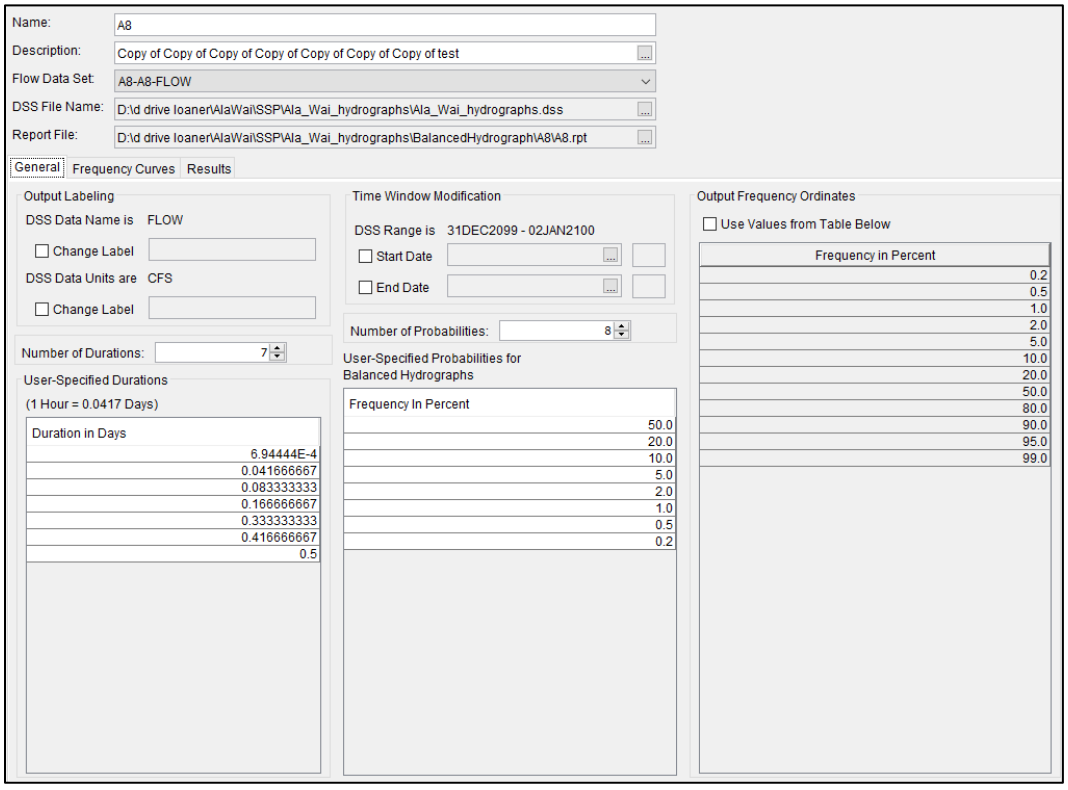

Figure 35: Balanced Hydrograph Editor

The various percent chance exceedance volumes were pulled from the HEC-WAT duration plugin frequency curves for each duration for each HEC-RAS input point. The analysis was then computed. This process creates a volume-balanced hydrograph at each location with peak flow timing based off the 0.01 AEP feasibility hydrographs. This method provides a more appropriate volume distribution throughout the watershed and allows for better model and design on the upper streams, specifically for overflow areas, constrictions, and diversions. A sample result is shown in the figure below and final output from the process is contained in the appendix.

Please note that a key assumption is that peak precipitation falls over the basin at the same time. This is appropriate to storm patterns experienced within the basin and is consistent with Atlas 14 methodology. As discussed in the Atlas 14 section of this report, this is also expected with larger storm events.

Uncertainty for Discharge Relationships in FDA

Uncertainty is needed in the discharge frequency calculations and is required by EM 1110-2-1619, chapter 4. This has also been reinforced by ER 1105-2-101. This uncertainty was added to the rainfall data and HEC-HMS model. A final overall frequency determination and uncertainty is needed for use in the HEC-FDA model.

The calibrated HEC-RAS model for this effort was used to develop a routed discharge frequency relationship using the expected HEC-HMS inflows for each frequency interval for each index location used in the HEC-RAS model. The HEC-RAS model was used for the streamflow routing due to the backwater effects and the ability to better match the index locations (not all were near an HMS compute node). HEC-FDA represents discharge uncertainty via a single estimated record length. Therefore, the HEC-RAS model was then used to route the 95% and 5% confidence limit flows (the 90% confidence interval) for the 0.01 AEP event. The 0.01 AEP event was selected as the priority for the current design storm frequency for the project. The 95 and 5% confidence limits were used in lieu of the 2 standard deviations (95% confidence interval) with 2.5% and 97.5% confidence limits because the HEC-WAT model does not currently produce the 95% confidence interval.

Wai1	2127	2483.02	2970.37	3699.9
Puk1	2723	3096.04	3378.48	4428.21

Two equations were used to estimate the standard deviation. These were: $X=\mu + Z\sigma$ and $\sigma=$ (minimum flow – maximum flow)/4. Where X is 95% flow, μ is the mean, Z is the standard Z-variate value relating to 2 standard deviations, and σ is the standard deviation.

The discharge-frequency relationship was entered directly into the HEC-FDA model and an ERL value was iteratively input until a reasonable match was found to the 2 standard deviations confidence interval.

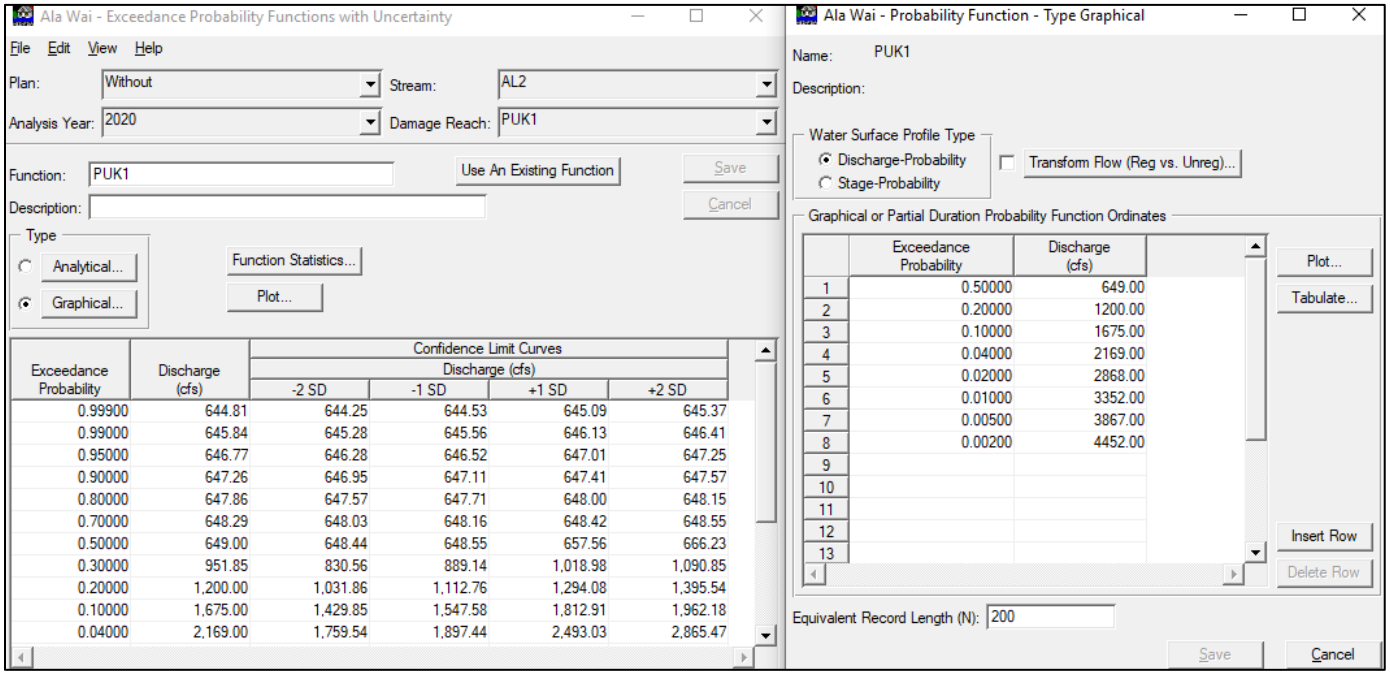

Figure 38: FDA Input for PUK1

This method was created well after publication, and therefore does not match well with any frequency method described by regulations, as shown below. After discussions with advisors, no reduction in ERL was taken, given the higher level of frequency computations.

Table 38: ERL Guidance for EM 1110-2-1619

EM 1110-2-1619

Table 4-5
Equivalent Record Length Guidelines

Method of Frequency Function Estimation	Equivalent Record Length[1]
Analytical distribution fitted with long-period gauged record available at site	Systematic record length
Estimated from analytical distribution fitted for long-period gauge on the same stream, with upstream drainage area within 20% of that of point of interest	90% to 100% of record length of gauged location
Estimated from analytical distribution fitted for long-period gauge within same watershed	50% to 90% of record length
Estimated with regional discharge-probability function parameters	Average length of record used in regional study
Estimated with rainfall-runoff-routing model calibrated to several events recorded at short-interval event gauge in watershed	20 to 30 years
Estimated with rainfall-runoff-routing model with regional model parameters (no rainfall-runoff-routing model calibration)	10 to 30 years
Estimated with rainfall-runoff-routing model with handbook or textbook model parameters	10 to 15 years

[1] Based on judgment to account for the quality of any data used in the analysis, for the degree of confidence in models, and for previous experience with similar studies.

The original feasibility study final equivalent years of record were selected based on the available gage data and the overall confidence in the reliability or accuracy of the peak flow discharge estimates. This

incorporated a significant portion of engineering judgement, and one equivalent year of record was assigned per stream segment. The updated values were assigned due to the ranges in flows calculated.

There is a significant increase in equivalent record length (ERL) between the two studies. This can be attributed to a much higher level of computationally intensive effort to reduce the uncertainty, a 310 year period of record in the Atlas 14 rainfall uncertainty which reduced the range of precipitation values, direct computations at each specific index locations (rather than estimates by reach), and significant backwater effects that at the higher frequency events limits the variability of flows within a stream.

Please note that a few FDA reaches were removed from the study, including UNI1, UNI2, and KAO1. These were removed due to the updating of the HEC-RAS model from one-dimensional to two-dimensional in areas, which removed some of the routing reaches approximating overland flow in the feasibility study.

Future Considerations/ Conclusion

Frequency routings were completed through a variety of methods. For the final design efforts, it is recommended that the 12-hour HEC-WAT routing be considered as the most accurate and appropriate. Final balanced hydrographs were developed for eight frequencies (50%, 20%, 10%, 5%, 2%, 1%, 0.5%, and 0.2% AEP) and for the 5% and 95% confidence limits of the 0.01 AEP storm event for each location in the HEC-RAS model. The HEC-WAT effort represents significant technological advances improving from frequency estimates from a single peak flow result of the feasibility study up to the Monte-Carlo style uncertainty analyses which incorporates significant amounts of Hawaii and Ala Wai specific data inputs.

Additional efforts that could be given considerations would be the inclusion of the precipitation patterns from topographically similar locations gathered from the other ongoing studies into the HEC-WAT model. Also, additional calibration to the model is recommended in any additional large storm events occur in the interim. In addition, specific areas will require detailed modeling of the urban drainage systems in later design phases to fully understand the impacts of urbanized runoff at specific project sites.

Introduction

The Ala Wai Canal Flood Risk Management project is located on the island of Oahu in urbanized Honolulu, Hawaii. The project would protect metropolitan Honolulu, the University of Hawaii, and Waikiki, Hawaii's economic center for tourism. The population at risk includes approximately 65,000 residents and an additional 200,000 transient visitors to the watershed daily (tourists, workers, students, etc.).

The canal overtopped and previously flooded Waikiki during the November 1965 and December 1967 storms, as well as during the passage of Hurricane Iniki in 1992. In October 2004, a storm flooded Manoa Valley, causing $85M in damages to the University of Hawaii, including the loss of irreplaceable documents in one of the libraries. Early modeling efforts indicated that a one percent annual flood exceedance event would result in damages to more than 3,000 structures in the watershed, with total damages of over $1.14B, and the majority of the damage in the downstream area of Waikiki.

Basin Description

The Ala Wai Watershed encompasses approximately 16.2 square miles and includes the drainages of Manoa, Palolo, Makiki, McCully, Moiliili, and Waikiki. The Manoa and Palolo streams join to form the Manoa-Palolo Canal. The Manoa-Palolo Canal, Makiki Stream, and three low lying drainage areas empty into the Ala Wai Canal, a two-mile long, man-made waterway constructed in the 1920s to drain wetlands, allowing the development of the Waikiki area.

The upper reaches of the basin are very steep and rocky and incised into the Ko'olau Volcano. This portion of the watershed ranges from 40 to approximately 2400 feet in elevation. The Makiki and Manoa basins typically receive more than 160 inches of rain annually, while the Palolo valley receives less.

The lower portion of the basin is much less steep and is extremely urbanized. Significant portions of this are impervious surfaces, with sewer system drainage actively directing most of the runoff in less intense events. The Ala Wai Canal and Waikiki basin receives about 30 inches of annual rainfall. High-Intensity rainfall on steep slopes of the small drainage basin can produce very flashy flood events. Time to peak is usually less than 1 hour and even for large intense storms, the rise and recession of the flood hydrograph usually occurs within 6 hours.

Study Phases

There were three phases to the Ala Wai Canal project, including the Feasibility phase, the Post-Feasibility Analysis, and the selection of the Proposed Final Features. The Feasibility study was completed in 2017 and is documented in *Ala Wai Canal Flood Risk Management Study O'ahu, Hawai'I Final Feasibility Study Report with integrated Environmental Impact Statement* Appendix A – Hydrology and Engineering (2017). The purpose of the Post-Feasibility study was to upgrade the steady 1D HEC-RAS model from the previous study with 2D areas and a switch to unsteady flow to improve the accuracy of the model. Once the model was updated and calibrated, the features from the tentatively selected plan (TSP) from the feasibility study were input into the model to determine their impacts to the 1% AEP (annual exceedance probability) flows. In addition, modifications to the features were evaluated to produce the most effective and optimal design for the watershed. After running multiple

design considerations, a final proposed design was chosen and modeled. Other frequency events were modeled once all the features in the study were modified and optimized.

Project features from the feasibility study included the following eleven individual structural elements and two non-structural components as carried forward from the feasibility study:

- Six debris/detention basins in upper stream reaches
- One stand-alone debris catchment structure
- Three multi-purpose detention basins
- Floodwalls along Ala Wai Canal (including pump stations for interior drainage)
- Flood warning system (non-structural)
- Fish and wildlife mitigation (non-structural)

The Post-Feasibility analysis analyzed the effectiveness of each of these structures and looked at different modifications to the six debris/detention basins in upper stream reaches, the three multi-purpose detention basins, and the floodwalls/pump stations around the Ala Wai Canal.

The Proposed final feature plan includes the following six structural elements and two non-structural components:

- Three multi-purpose detention basins
- Two stream diversions
- Floodwalls along Ala Wai Canal (including pump stations for interior drainage)
- Flood warning system (non-structural)
- Fish and wildlife mitigation (non-structural)

Previous Modeling Efforts

The original study was developed using the HEC-RAS (Hydrologic Engineering Center - River Analysis System) computer program, version 4.1.0 for hydraulic modeling (*U.S. Army Corps of Engineers, 2010*). This HEC-RAS model was created by joining separate HEC-RAS models of Makiki, Manoa, and Palolo Streams and Manoa-Palolo Drainage and Ala Wai Canals. The HEC-RAS model of Manoa Stream is documented in the Final Hydraulic Report, Manoa Watershed Project (Oceanit, *2008b*) and the separate models for the Makiki and Palolo Streams and the Manoa-Palolo Drainage and Ala Wai Canals were originally created by Oceanit and West Consultants by July 2009 and then corrected and merged together by the U.S. Army Corps of Engineers by November 2009. In 2013 the merged model was then updated again to be more accurate. This model consisted of 8 rivers, 13 reaches, 1,287 cross sections, of which 476 are interpolated, 49 bridges (this includes culverts), 2 inline weirs, and 16 lateral weirs. Modifications were made to the model and report in March 2016, August 2016, and February 2017. This effort is detailed in the *Ala Wai Canal Flood Risk Management Study O'ahu, Hawai'I Final Feasibility Study Report with integrated Environmental Impact Statement* Appendix A – Hydrology and Engineering.

A list of previous reports with descriptions is included in section 2.2 "previous hydrologic and hydraulic models and studies." These include:

- Federal Emergency Management Agency's National Flood Insurance Program Study (FEMA, 1979)
- Ala Wai Canal Improvement Project, Storm Water Capacity Study (Edward K. Noda and Associates, 1994)
- Ala Wai Flood Study (USACE, 2001)
- Ala Wai Watershed Analysis (Townscape Inc. and Dashiell, 2003)
- Hydrology and Hydraulics Study, Flood of October 30, 2004, Manoa Stream (USACE, 2006)
- Final Hydrology Report, Manoa Watershed Project (Oceanit 2008a)
- Final Hydraulic Analysis Report, Manoa Watershed Project (Oceanit, 2008b)
- Technical Summary Report, Manoa Watershed Project (Oceanit, 2008c)
- Final Hydrology Report, Ala Wai Watershed Project (Oceanit, 2008d)
- Final Drainage Evaluation Report, Ala Wai Canal Watershed Project (Oceanit, 2008e)
- Conceptual Engineering Report, Ala Wai Canal Flushing System & Ala Wai Golf Course Detention System (Mitsunaga & Associates, Inc., 2014)

Project Scope

In an effort to improve upon and extend previous modeling efforts the project the following adjustments were made to the 2016 Ala Wai Hydraulic efforts.

- Update model to most recent published version (HEC-RAS Version 5.0.7)
- Modify Geometry to include 2 dimensional (2D) areas for the overbanks where needed
- Review bridges, tunnels, and other existing features in previous model
- Incorporate new terrain data and modify in areas where new features will be added
- Incorporate land cover data for 2D roughness values
- Update model to unsteady flow which is needed for 2D modeling and re-link model to new HEC-HMS flows as discussed in the Hydrology section
- Calibrate and validate updated model to the 2004, 2006, and 1967 events.
- Creation of Alternative geometries for project features.
- Routing of 100-year frequency with different modified geometries.
- Compiling a final report for inclusion with the hydraulics updates.

As will be detailed in this report, upper basin project features have largely been removed and a single without project geometry was brought forward for the final frequency and uncertainty routings.

The table below lists all the HEC-RAS model scenarios as part of this study and includes the associated geometry and flow files for each model scenario. The features included in each scenario will be described in later sections of this report.

Table 1: HEC-RAS Plan, Geometry, and Flow Files

Standard Units

Unless otherwise specified all units are as follows:

Precipitation- Inches (In)

Flow – Cubic Feet per Second (CFS)

Runoff Volume – Inches (averaged over the upstream drainage area of a given point)

Area- Square Mile (Mi^2)

Storage Volume – Acre feet (acre-ft)

Elevation- Feet, Local Tidal Datum-mean sea level (LMSL), Tidal Epoch 1983-2001. Geoid 2012A

Projection- NAD 1983 HARN projected to State Plane Hawaii 3 FIPS 5103 feet, Horizontal

Hydraulic Model Setup

Overview

The updated hydraulic modeling was developed using the HEC-RAS (Hydrologic Engineering Center - River Analysis System) computer program, version 5.0.7. This version of HEC-RAS has the capability to model one dimensional (1D) and two dimensional (2D) flows. The updated HEC-RAS model utilizes the same 1D channel cross-section data but the overbank areas are modeled with 2D grids rather than having the 1D cross-sections extend into the overbank or in some cases creating false "stream reaches" to model the overbank. The channels were left as 1D cross sections because the current version of HEC-RAS lacks the capability to model bridges and other complex structures in 2D flow areas. The hydraulic modeling was also converted to an unsteady flow analysis from steady flow analysis in the previous study. The unsteady flow model incorporates and routes the variable flows with adjustments for channel roughness, geometry, and constrictions like bridges and debris blockages. The unsteady model's ability to simulate changes to the hydrograph, flow, and water surface elevation over time allow for more accurate representation of hydraulic routing of flow through the watershed. Also, some of the longer culverts were converted to lids to allow more cross-sections over longer lengths which increased stability. Other changes included updating the channel roughness, making specific bridge modifications based on field visit, adding a bridge for Kapiolani Blvd on the lower Makiki Reach, modifying roughness in the overbanks to account for buildings, and switching to uniform lateral inflow to better distribute local inflows when appropriate. The downstream extent of the model was extended into the ocean so that the downstream boundary condition does not unintentionally force potential errors in the canal. Finally, a better-quality terrain was implemented for the study.

Since this project was designed for a 1 percent annual exceedance probability (100-year AEP) event during the feasibility study, this effort primarily focused on the 1% AEP flows for model scenarios and modifications to the feasibility features. Once a decision was made on which features will be included in the final design, the other frequencies were modeled in order to be incorporated into the economic models. Further discussion on the preparation of the hydraulic data for the economic model can be found in the last section of this report titled "Hydraulic Information for Economic Analysis".

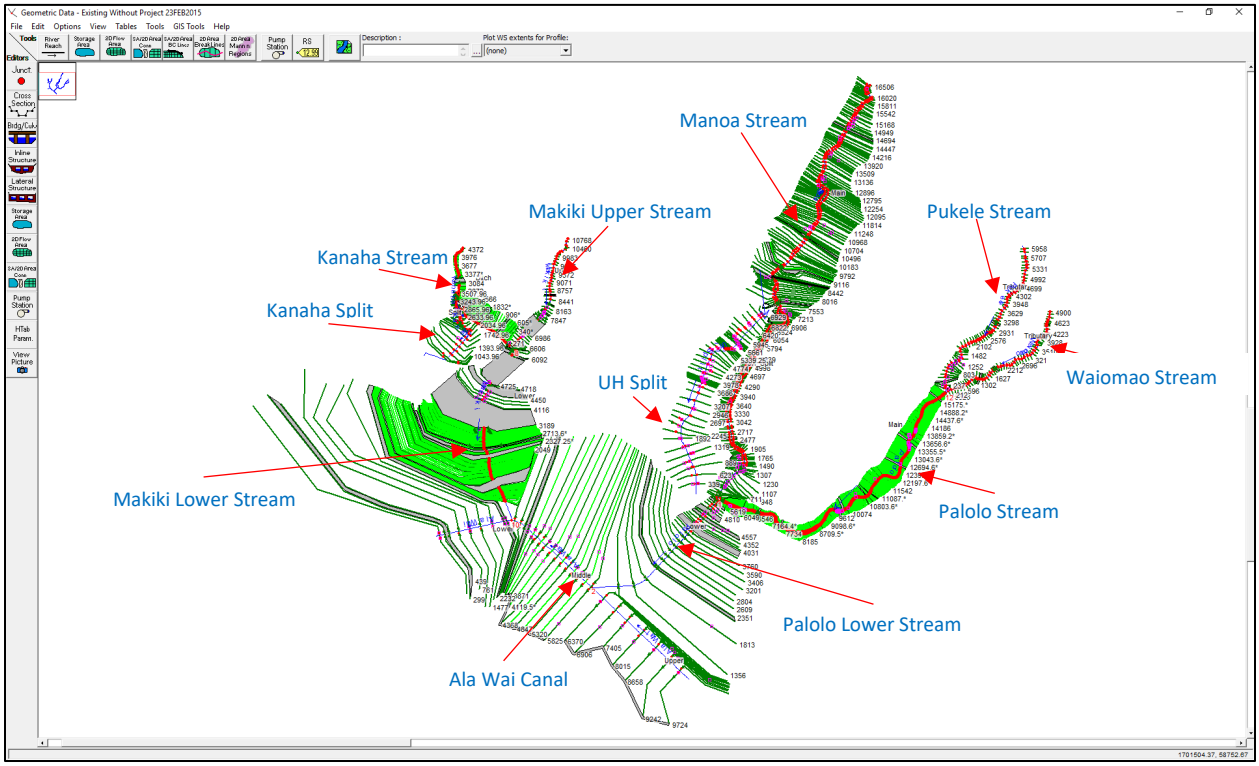

Figure 1: Original HEC-RAS Geometry Schematic

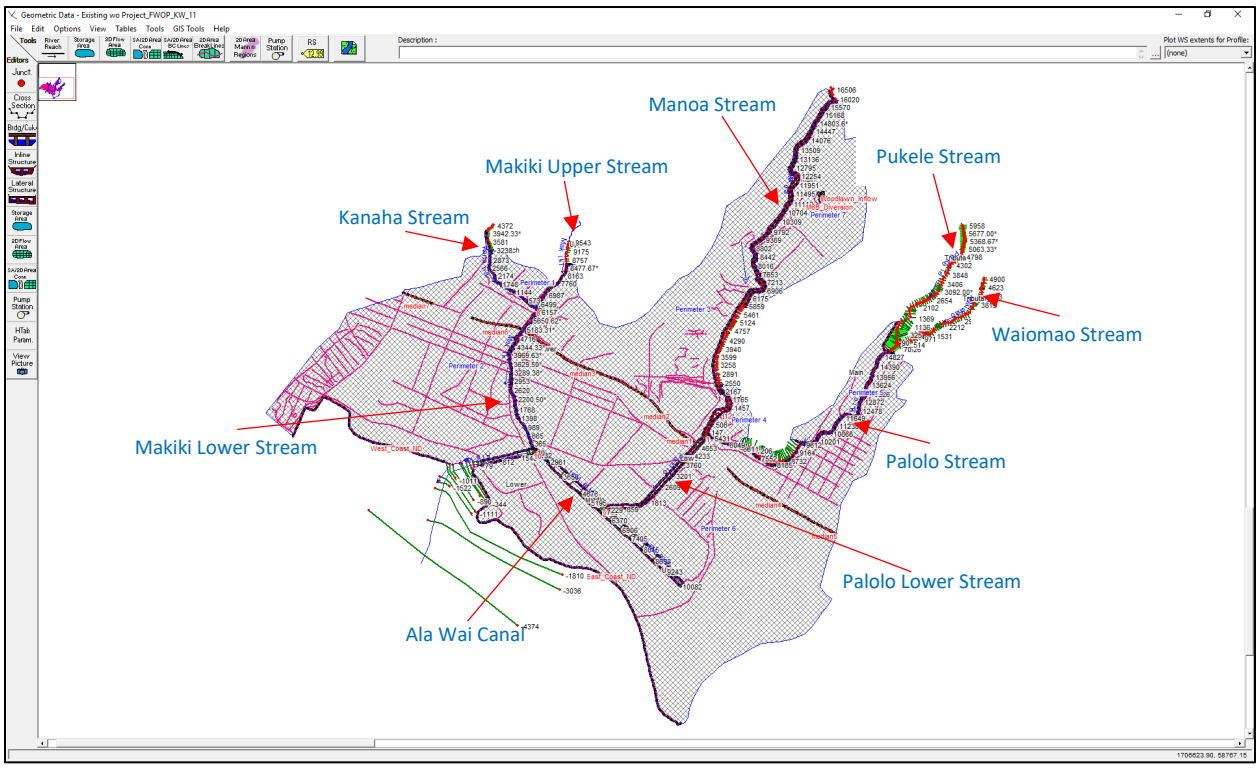

Figure 2: Updated HEC-RAS Geometry Schematic

Study Reaches

The Makiki Stream portion of the HEC-RAS model starts from the confluence with the Ala Wai Canal to a point approximately 2.0 miles upstream and includes the Kanaha Ditch Tributary from its confluence with Makiki Stream to a point approximately 0.8 miles upstream. The Makiki Reach was modified to add the Kapiolani Blvd Bridge near the confluence with the Ala Wai Canal. This bridge was left out in previous studies. This bridge is critical in modeling both the backwater and headwater effects of this constriction, especially since the proposed Ala Wai floodwalls from the tentatively selected plan (TSP) involves tying the floodwalls into the bridge. However, the pedestrian walkway bridges were ignored in the model because they appear sufficiently high to not impact water surface elevations. The stream channels of both Makiki and Kanaha Streams have been highly modified with concrete and confined from the point when they enter the urbanized area and include sections when the stream channel is confined to sections entirely underground.

The Manoa Stream reach extends from the confluence with Manoa-Palolo Drainage Canal upstream about 3.1 miles to the point where the Waihi and Waiakeakua Stream tributaries meet. The Manoa Stream channel is mostly natural with some segments modified by concrete channel or stream bank hardening.

The Palolo Stream Main reach extends upstream approximately 1.9 miles from the confluence with the Manoa-Palolo Drainage Canal. Upstream of Palolo Stream, the Pukele Stream and Waiomao Stream tributaries were modeled, extending 1.1 and 0.9 miles upstream. The Palolo Stream Main reach channel is mostly confined to one large concrete channel with a few segments composed of natural channels.

The Manoa-Palolo Drainage Canal is called the Palolo Stream Lower reach in the model and extends about 0.9 miles from the Ala Wai Canal to the confluence of the Manoa and Palolo Stream. This canal consists of a modified channel with segments of natural bed and banks, but mostly hardened stream banks.

The Ala Wai Canal section is modeled using three reaches from the mouth of the to the Makiki Stream confluence (Lower), from Makiki Stream to the Manoa-Palolo Drainage Canal confluence (Middle), and from the Manoa-Palolo Drainage Canal confluence to the upstream end (Upper). The Ala Wai Canal channel has a natural bottom with hardened banks and has tidal influence. Bathymetric data was collected by Oceanit in 2008 and used to compute the cross-section data for the canal.

Terrain

Topographic data for the hydraulic model is primarily based on airborne light detection and ranging (LIDAR) data. The terrain used for this study was generated from 3 different data sources. The terrain data included SHOALS (Scanning Hydrographic Operational Airborne LiDAR Survey) data for the bathymetric coastal waters, LiDAR that was originally collected prior to February 21, 2007 by Airborne1, and bathymetric survey data for the Ala Wai Canal that was conducted by Oceanit on May 12, 2008. The airborne LiDAR data was collected, processed, and verified by Oceanit and their sub consultants in late 2006 and early 2007. The LiDAR data has an accuracy of 45 cm (1.5 ft) horizontal, 37 cm (1.2 ft) vertical and was processed with 1 ft horizontal point spacing. Datum of data is NAD 1983 HARN projected into Stateplane_Hawaii_3_FIPS_5103_Feet horizontal and mean sea level vertical. The quality of the terrain data used in the HEC-RAS model has been updated compared to the terrain data that was provided for

the original model which was based on a 3 ft horizontal point spacing. The figures below show the difference between the datasets. It's suspected the reduction in the quality of the terrain data was due to conversions that were deemed necessary during the original study. The documentation from the previous study indicates that the terrain data was converted to a TIN (Triangulated Irregular Network) for the application of HEC-GeoRAS which may be the cause of the triangulated areas in the floodplain. The mountainous regions appear to match the LiDAR for the current study and only the flat floodplains areas seem to have been degraded in the previous study. The higher quality terrain was also modified to remove some bridge decks that were not properly removed so that water could move freely in these areas. In addition, the channel data from the existing HEC-RAS cross-sections was used to burn-in channel bathymetry in the terrain to provide improved mapping for the channels. Finally, the terrain for some scenarios was modified to include some of the proposed structures such as Makiki Detention Basin, Pukele Detention Basin, Waiomao Detention Basin, and a deeper sedimentation basin within the golf course. These scenarios included modifications 1 – 8, the TSP plan, and the final proposed features plan. The detention basin terrain was produced by the detention basin designers from the Seattle District. They provided the updated terrain from their CAD software. To incorporate this into the HEC-RAS terrain data, the detention basin terrain was selected as additional terrain data along with the channel terrain data and the LiDAR terrain. The detention basins were set as top priority, followed by the channel terrain and then finally the LiDAR terrain. HEC-RAS created a tiled terrain dataset using all the provided terrain datasets.

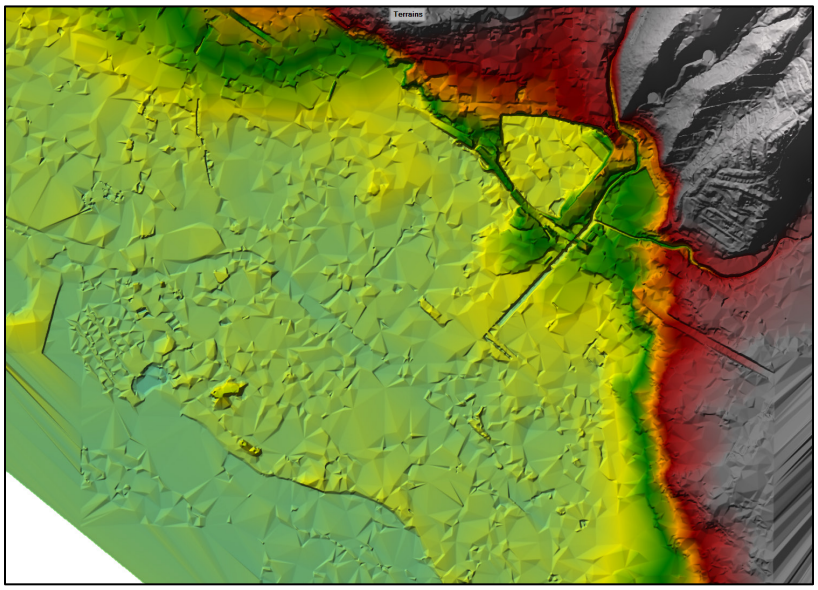

Figure 3: Terrain Data provided with Original Model

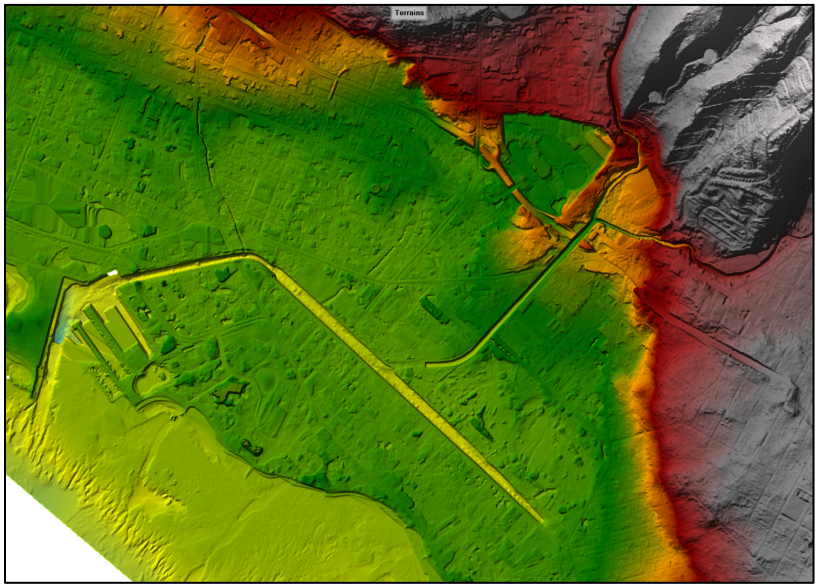

Figure 4: Terrain Data used in the Updated HEC-RAS Model

In addition to the topographic data, additional survey data was collected to improve the modeling. Surveys were collected for the wall along the left bank of the Manoa Stream from Kanewai Field to the confluence with the Palolo Stream. This survey data was input directly into the model as a lateral structure.

Cross-Sections

Overview

The updated hydraulic model uses 1D cross-section for the channel and 2D flow areas for the overbanks except for the Pukele and Waiomao reaches which used the same cross-section data from the previous study. In addition, the upstream portions of Kanaha and Makiki also used the full cross-section extent because these areas are steep, highly gravity driven, have small overbanks, and the dominant flow direction follows the general river flow path which make them appropriate areas to be modeled by 1D geometry.. For areas with 2D flow areas, the original 1D cross-sections were trimmed to the channel area. This included trimming bridge data and other structures data to the reduced cross-sections. The original channel data in the 1D cross-sections was retained for this study. In addition, since the overbanks are now modeled with 2D areas, the “dummy” reaches from the previous study were removed since the 2D would be to model these areas more appropriately. The “dummy” reaches that were removed included the “UH_Split” reach and the “Kanaha Split” reach. These “dummy” reaches were 1D reaches that were added into overbank areas to simulate flow that has left the main channel and flowed along the overbank areas through the University of Hawaii (UH_Split) and south of the Kanaha Stream (Kanaha_Split). There are no real channels that exist in these areas, but the reaches were added to simulate overland flow. Additional cross-sections were added to the model to extend the Ala Wai Lower Reach further into the ocean to prevent forcing a water surface elevation at the end of the study area. The Ala Wai Upper Reach was also extended further upstream near the end of the canal. The previous model started the reach about 300 feet downstream of the east end of the canal near the public library.

Ineffective Flow

Since the cross-sections were reduced to the channel extents for most areas, ineffective areas were not necessary for most of the modeled cross-sections. However, any ineffective areas that were used in the previous model where the full cross-sections were retained (i.e. upper reaches of Kanaha, Makiki, Pukele, and Waiomao), the ineffective areas were preserved. In addition, any ineffective areas that were located around bridges and within the new reduced cross-section footprint, were also preserved.

Manning's "n" Roughness

Manning's n-values were determined based on-site visits conducted by personnel from MMC, HEC, and POH for the different reaches. The site visits were conducted 6-8 November 2018. Due to the lack of calibration data throughout the watershed, the roughness was estimated based on a consensus of several senior hydraulic engineers that participated in the site visits to ensure reasonable values were used for the channels. Since the 1D cross-sections were only used to model the channel portion, a composite 'n' value was used for the entire channel portion which would include the sides of the channels.

The range of Manning's n-values used can be roughly characterized by channel description. A summary of Manning's n-values used in the HEC-RAS model can be found in Table 1. Natural stream channels with minimal vegetation in the channel, steep banks, trees and brush on banks, and bottoms consisting of gravels, cobbles, and few large boulders were given values from 0.04 to 0.08. Natural channel sections that were uniform and contained smooth graveled beds were given a value of 0.028. The Ala Wai Canal was given an n-value of 0.03. Lined or concrete channels were given a value of 0.022 to 0.025. For concrete lined channels on the Palolo, the roughness was estimated to be approximately 0.022 due to the aged concrete, exposed aggregate, and steepness. For Makiki, concrete lined channels were given a value of 0.025 due to the sedimentation, plant growth along the wall, and the rougher side walls that were made with lava stone. The majority of overbank areas in mixed urban areas or overland flow areas were given values of 0.07 to 0.125. The overbank values varied based on the landuse type in the overbank. For example, overbank cross-sections that intersected open park areas had a lower value compared to those that more vegetation or higher density of buildings. Manning's n-values for the study reaches is show in Table 1.

Bridges and Culverts

Bridge data from the previous model was utilized in the updated model. Site visits were conducted on several bridges to verify dimensions and the model was updated accordingly. In addition, the Kapiolani Blvd Bridge on the downstream of Makiki was added to the model between RS 555 and 425 and the Woodlawn Drive Bridge on Manoa was updated reflect recent improvements to the channel at the bridge and downstream of the bridge between RS 7885 and 7290. For the Kapiolani Blvd Bridge on Makiki, an inspection report dated January 2018 was used to estimate dimensions. For the Woodlawn Drive Bridge improvements, plans were provided by the State of Hawaii Department of Land and Natural Resources (DLNR). The improvements included removing sediment and debris accumulation approximately 40 feet upstream of the bridge, under the bridge and approximately 500 feet downstream of the bridge. In the vicinity of the bridge, the sediment and debris was removed down to the concrete and riprap bottom of the channel. Downstream of the bridge, the channel was graded on a 0.5% slope for approximately 500 feet. Since the Woodlawn Drive improvements were made after the last observed calibration event (i.e. 2006), the improvements were not included in the calibrated geometry but were included in all the other geometries including the "without project" geometry. The improvements at Woodlawn Drive will reduce the water surface elevation (WSEL) around this area and would reduce the amount of flow leaving the channel at the Woodlawn Drive area which should reduce the amount of flooding through the University of Hawaii. Since the primary flooding of the 2004 flood event was at the University of Hawaii and was due to the restricted flow and debris at the Woodlawn, it would not be appropriate to use the improvements for the calibration events. During a November 2018 site visit, this area was still under construction but was eventually finished in time for the improvements to be added to the model. Unfortunately, due to the lack of instrumentation in the areas and lack of observed data since the improvements were complete, the model could not be calibrated with the improvements. Using the 1967 event since it was a high flow event on the Manoa Stream but did not have the debris issue at Woodlawn Drive Bridge like the 2004 event, a sensitivity was performed to determine the potential impact of these improvements. With the improvements, the WSEL above the Woodlawn Bridge dropped a maximum of approximately 3 ft right at the upstream face of the bridge

but increased the WSEL downstream of the bridge between approximately 0.5 to 1.0 ft due to the increase conveyance under the bridge. For the 1967 event, the Woodlawn Drive Bridge improvements allowed an additional approximately 1,000 cfs through the bridge. These impacts were seen on Manoa Stream downstream of the Woodlawn Drive bridge to the confluence with the Palolo Stream.

The updated model also converted the culverts and bridges on the Makiki Reach to cross-sections with lids. This was done to increase stability in the area and to more appropriately model the longer culverts that go underground for several city blocks. Having cross-sections with lids, allows multiple cross-sections along the length of the culvert rather than having cross-sections only on the upstream and downstream ends of the culverts. The use of lids still allows a reduction in conveyance when the conduits flow full because when the water level hits the low chord of the culvert or bridge, the program increases the wetted perimeter to account for the bottom of the lid. Since the culverts were underground, the top of the lids were artificially raised to prevent water from flowing over the top of the lids since most water would flow into the overbank areas if the water surface elevations rise high enough and flow on top of the lids was not deemed to be realistic. In addition, Priessmann slots were used for several of the lids to allow for both open channel and pressurized flow in the conduit. Without this feature turned on, HEC-RAS would not be able to account for the effects of pressure flow in the conduit. According to the HEC-RAS 5.0 Hydraulic Reference Manual, HEC-RAS uses the Priessmann slot theory which suggests that pressure waves can be simulated by equating the wave celerity to the acoustic celerity. When the Priessmann slot is turned on in HEC-RAS, the program inserts a slot of a constant width and infinite height above the top of the conduit with the width of the slot being determined by the equating the celerity wave to the acoustic wave. When the water is high enough (i.e. at the top of the conduit) the wave celerity will be equivalent to the acoustic wave. A sensitivity was performed for some of the shorter bridges that were modeled as lids with the Priessmann slot turned on and off. The analysis showed that the shorter bridges were not sensitive to the Priessmann slot option which was most likely due to the fact of the shorter distance where the wave celerity was equated to the acoustic wave was not of significant length to significantly impact the flow through the bridge. However, for the longer culverts on the Makiki and some on the Kanaha reach would be impacted. As a result, the Priessmann slot was used in the model.

For the calibration and the without project conditions, several bridges were modeled with simulated debris. The 2004 event in particular had additional debris problems on the Woodlawn Drive Bridge and for this particular event, a blocked obstruction was used on the cross-section (RS 7819) just upstream of Woodlawn Drive Bridge to simulate the debris blockage on that bridge during the 2004 event. The dimensions of the debris were carried over from the previous study. The debris was modeled as either a blocked obstruction on the upstream cross-section for bridges or as depth blockage for structures modeled using the culvert feature in HEC-RAS. Table 2 provides a list of bridges in the model and if debris was applied to the bridge.

Inline Structures

Several inline structures were used in the model to increase the stability around steep drops in the channel profile. An example is the steep concrete drop off just upstream of Lowrey Ave and the waterfall that is on the downstream end of the Manoa Channel just upstream of the confluence with the Palolo Channel. Table 3 list the inline structures in used in the model.

Waiomao	Tributary	4489	Feature from previous model (no documentation of structure)

Lateral Structures

Lateral structures were used to transfer flow between the 1D channel sections to the 2D flow areas. For most of these connections, the "normal 2D equation domain" was used as the overflow computational method since the connection represented overland flow and not a weir type structure. However, some connections were modeled using the weir equation because these areas had walls or other features that may act like weirs such as raised walls along the Makiki Reach and the lateral structure connecting the Manoa Reach to the Kanewai Field since this area has a concrete wall and for the with project condition it will have a weir to allow flow into Kanewai Field. In addition, some lateral structures were manually edited in locations where the terrain data was not properly defining some features. For example, the lateral structures along the Makiki were raised to match the top of bank since this is a concrete lined channel, with known dimensions. The lateral structure on the east bank of the Manoa reach between Kanewai Field and the confluence with Palolo was modified with survey data that was collected to better define a wall along Koali Rd. The lateral structure elevations were also modified on the Makiki reach where lids were used to prevent the flow over the lateral structures since the flow would be underground and could not realistically overtop the lateral structure.

Two-Dimensional Flow Areas

Overview

2D flow areas are used extensively throughout the model for the overbank areas due to the lateral flows and multiple flow paths in the wide and flat floodplains, which are more accurately modeled with 2D versus 1D modeling. In total, seven 2D flow areas are used to represent the overbank areas of the Kanaha, Makiki, Manoa, Palolo, and Ala Wai channels. The average cell size is approximately 80 ft with the largest cell being approximately 200 ft. There are almost 200 breaklines in the model to more accurately model hydraulically significant features with some breaklines having spacing as small as 10 ft cells. There are approximately 31,000 cells across the seven 2D flow areas.

Internal Hydraulic Structures

In addition to breaklines, internal hydraulic structures were used in multiple locations in the 2D flow areas. It was determined that the median barrier along H-1 could impact the flow path, but it was not included in the terrain. Plans were located and the median was found to be approximately 4'8" in height. The height of the median barrier was added to the underlying terrain to represent this barrier. The median barrier was not modeled along H-1 where there were underpasses since the median would not obstruct the flow under the bridges. Features modeled as connections include several project features such as the Golf Course berm, Hausten Ditch berms, Kanewai Field berm, and the Woodlawn Detention Basin berm that will be described in other sections.

Manning's "n" Roughness for 2D

The roughness of the 2D areas were based on the 2011 Coastal Change Analysis Program (C-CAP) Land Cover for Oahu. The land cover data was supplemented with building footprints from a 2009 dataset from the National Geospatial-Intelligence Agency (NGA). Manning's roughness for some land cover fields were estimated using values from *Zhang, K & Yuepeng, L. 2017 "Transition of the Coastal and Estuarine Strom Tide Model to an Operational Model for Forecasting Storm Surges" Florida International*

University. The figure and table below show the values used for the 2D land cover data. For buildings, a high 'n' value was used to reduce conveyance but will also allow for some storage of the water. At first the buildings were set to a roughness of 99.0 but this was found to be too high since water was completely prevented from entering some cells. This number was eventually lowered to a 9.9 based on judgment since there is not clear reference material available to estimate this value. In addition, two Manning's override regions were created to overwrite and better represent the land cover in those areas since the current version of HEC-RAS does not allow for horizontal variation in Manning's n-values on a single cell face. These two particular areas were causing the water to unrealistically pile up in adjacent cells because the entire cell face was using the manning's value for buildings and so the water had nowhere else to go even though some water would be able to flow through the area since part of the cell face would be open to allow water through. Other cells that were using the building Manning's "n" value had other cells for the water to go around and did not artificially cause the water to pile up inside a cell but did allow the water to slow down in this area which was the point of having the building footprints in the Manning's layer. The first override region was placed in the vicinity of the Century Center on the right bank of the Makiki Lower reach near the confluence with the Ala Wai Canal (see Figure 5 below). This building has a partial ground (pg) opening at ground level for parking areas and would allow more flow through this area around the parked cars compared to a solid building and would prevent the WSEL in this area from unrealistically backing up several feet high in the cell to the northwest. The other override region was placed north of the Palolo Main reach around cross-section 10868 (see Figure 6 below). This particular cell face was using the building Manning's "n" value but there are areas of partial ground (pg) that would allow flow through this area and based on the terrain in the area, the flow could easily flow to the north and around the cell face, so the cell was unrealistically causing the WSEL in the cell to the east to pile up multiple feet compared to the adjacent cells. The override region was used to lower the roughness on the cell face and allow water to flow around buildings in that area.

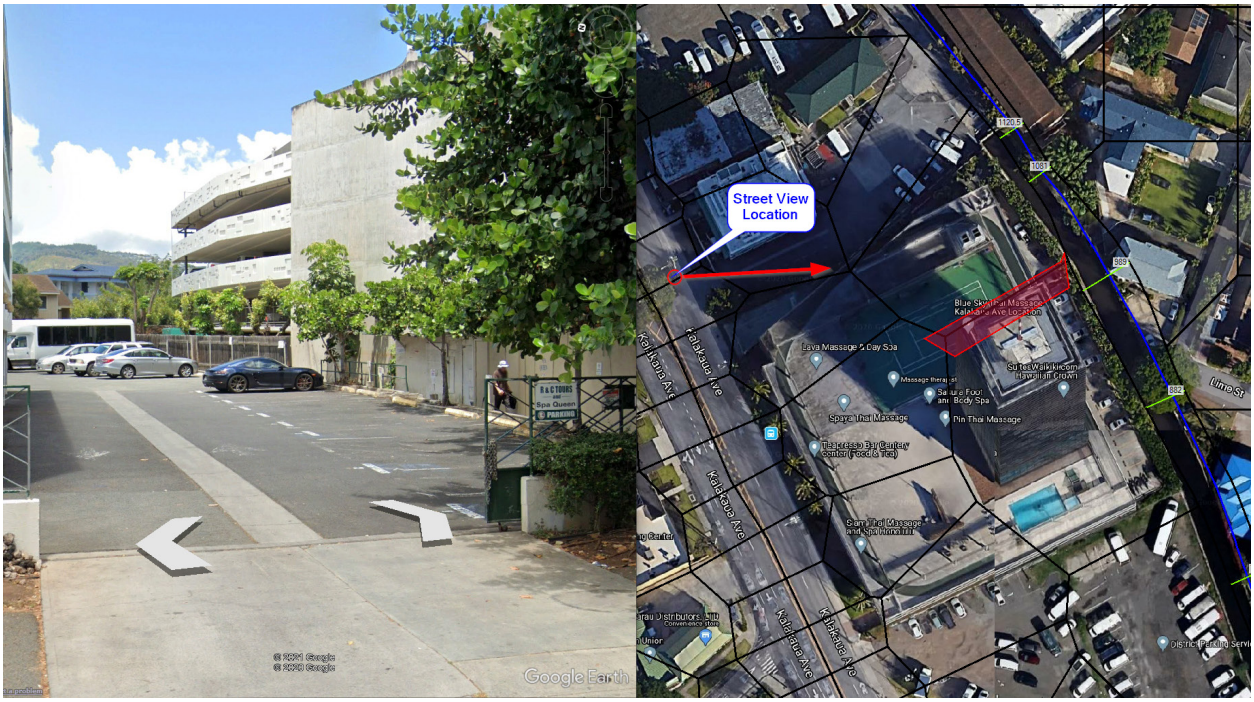

Figure 5: Manning's Override Region along Makiki Stream

Figure 6: Manning's Override Region along Palolo Stream

Boundary Conditions

Since the updated HEC-RAS model is using unsteady flow compared to the steady flow that was used in the previous study, flow hydrographs were needed for the model. Results from the HEC-HMS frequency flows were used throughout the HEC-RAS model. The downstream boundary condition of the Ala Wai Canal was modeled as a stage hydrograph using a stage of 2.05 ft LMSL for the existing conditions and 2.50 ft for the future conditions. The elevation represents a combination of the mean high high water (MHHW) tide at the Honolulu Harbor tide gage coupled with inter-annual variability (IAV) and sea level rise. The MHHW was set to 1.08 ft LMSL and the IAV is 0.4 ft. The 2.05 ft LMSL elevation used for existing conditions represents a high sea level rise base condition predicted for the year 2025. The 2.5 ft LMSL elevation used for future conditions represents an intermediate sea level rise for the year 2075. The years 2025 and 2075 represent the bounds of the estimated 50-year design life. The sea level rise

elevation used for 2025 and 2075 were determined as part of the feasibility study. For this report, all scenarios were based on future year 2075 conditions.

Additional boundary conditions were placed on the 2D flow areas near the coast which included a normal depth boundary condition to allow for the water to exit the system since at this point the water would enter the ocean. The normal depth friction slope was based on an average ground slope around the area of the boundary condition line. The 2D boundary perimeter was located along ground higher than the max tidal elevation used in the model so that 2D flow area would not be inundated or impacted by tides but was located close enough to the ocean to map runoff inundation from interior flooding. The tables below include the boundary conditions used in HEC-RAS for the without project conditions and the Final Proposed Features condition. The boundary conditions that use HEC-HMS flows are indicated by the HEC-HMS feature in the fourth column and the data type in the last column. In addition, the table also includes the other boundary condition types and the associated type of connection. The final proposed features can be found in the Final Proposed Features section of this report.

Since the 1D cross-sections in the version of HEC-RAS that was used for this study cannot be dry, some minimum base flow was needed to maintain stability because the HEC-HMS hydrographs started with zero flow. The base flow was applied only to the upstream of each reach for the Kanaha, Makiki, Manoa, Pukele, Waiomao, and the Bypass reach. Since the Palolo was downstream of Pukele and Waiomao, it did not need an additional base flow. In addition, since the Ala Wai Canal would be filled to some level due to tidal conditions, a base flow was not necessary for the canal. The channel invert of the Ala Wai Canal is less than the tidal boundary of 2.05 ft LMSL for existing conditions and 2.5 ft LMSL for future conditions and so the channel will remained filled to some degree for the entire simulation (see figure below). All base flows were lower than the peak flow of the 2-year annual frequency event with the exception of the Bypass Reach which does not have a 2-year frequency flow. For that reach a base flow of 25 cfs was added so that the model would run and that was flow was developed under trial and error to determine the smallest flow required to prevent instabilities for low flows. The table below describes the base flows that were used in the model and the comparison of the peak flow from the 2-year annual frequency flows at those respective locations. The peak 2-year frequency flow was determined from the post-feasibility HEC-HMS model using the basin average Atlas 14 rainfall.

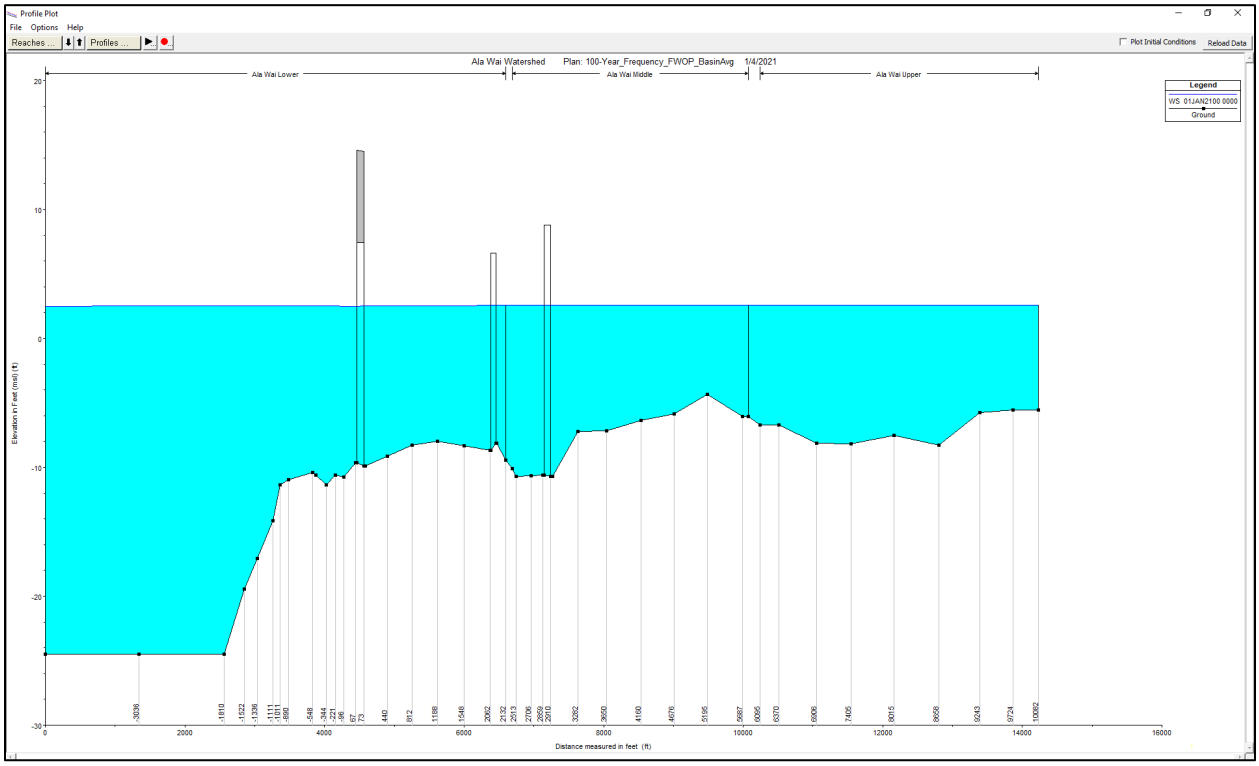

Figure 8: Ala Wai Canal Channel Profile with Tidal Boundary

Table 8: Base Flows used in HEC-RAS

Base Flow Information				
Model Stream Names		Model Cross-Section Location	Base Flow (cfs)	Peak Flow for 2 Year AEP (cfs) from HEC-HMS routed Atlas 14 Rainfall
River	Reach			
Kanaha	Ditch	4372	90	140
Manoa	Main	16506	500	1120
Pukele	Tributary	5958	200	380
Waiomao	Tributary	4900	200	450
Makiki	Upper	9543	200	230

Calibration and Without Project Scenario

Overview - Calibration

Three events were provided for calibration of the model. At the time the original study began, there have been only 3 significant events in the observed record, and these events, the 1967, 2004, and 2006 were used. Observed flows were not available in the detail needed to calibrate an unsteady model, so the HEC-HMS model was used to route the rainfall from those events and provide inflows into the model. It should be noted that only the Manoa-Palolo portion of the basin was available for the 2006 event. See the Hydrologic Report for this study to find out more about the HEC-HMS calibration for these 3 events.

Previous modeling on Manoa Stream (*Oceanit, 2008b*) was calibrated to the 2004 flood event on Manoa Stream. Previous modeling of the Ala Wai Canal (*U.S. Army Corps of Engineers, 2001 and 2005*) was calibrated to the limited data of the 1967 event on Palolo Stream and Manoa-Palolo Drainage Canal. Makiki and Kanaha Streams do not have any calibration or gaged data to aid in calibration or model comparison but are mostly concrete lined channels so the n-values should be stable. Calibrated n-values are assumed to also account for any sediment or debris "bulking" during those storm events.

The Ala Wai Watershed contains several active and inactive USGS Stream Gages, but the data is only reported on a daily interval. Due to the relatively rapid rise and fall of the flood wave (typically the flood wave passes within a few hours) the daily stage and/or discharge data was not adequate for calibration. However, Appendix A2 of the previous feasibility report from March 2017 did provide some comparison data for three of the USGS stream gage stations. This data can be found below in Table 8. There was at least one difficulty with the data which was that the gages are operated using a gage datum that does not correspond to a known datum (e.g. mean sea level) and so for the previous study an approximation of the gage datum had to be made to compare with the HEC-RAS model datum (i.e. LMSL). As stated in the Appendix A2 of the feasibility report, the approximation was made based on information provided by the USGS at their gage locations and the elevation data of the nearest HEC-RAS model cross-section. The Appendix A2 states that it was estimated for the feasibility 1D modeling that the conversion had a 1-foot error and that an additional difference of +/- 0.7 foot would result from model error and USGS rating curve error. The discharge value comparison from Appendix A2 is based on a common discharge values from the station rating curves and the HEC-RAS model results at that location. At USGS station 16242500 Manoa Str at Kanewai Field, Honolulu, Oahu, HI, two water surface elevations were computed for the conversion since the data points for the conversion were more vague than the other two locations. Table 8 includes the information from the feasibility study. The new results from this 2020 study were added to the last column. As can be seen from the comparison, the water surface elevations compare closely with those of the previous study and are within the expected error of +/- 1.7 feet.

Table 9: WSEL Comparisons at Select Locations between USGS Gages and HEC-RAS Model Outputs

USGS Gage Station Number	HEC-RAS Model Reach	HEC-RAS cross-section Location	Comparison Discharge (CFS)	Gage Water Surface Elevation Converted to Model Elevation	HEC-RAS Model Water Surface Elevation – 2017 Original Model	HEC-RAS Model Water Surface Elevation – 2020 New 1D/2D Model
16242500	Manoa Main	1230	4,450	36.4 or 38.8	38.07	38.02
16247000	Palolo Main	9520	1,200	96.2	95.72	95.92
16247100	Palolo Lower	3201	10,910	11.9	12.93	13.02

In addition to this limited data, some qualitative comparisons were made to ensure that model was producing reasonable results. For example, the 2004 event was known for flooding that flowed through the University of Hawaii after the flow left the channel at Woodlawn Drive Bridge due to debris pileup. There was also some shallow flooding observed on the downstream end of the Makiki near the confluence with the Ala Wai Canal. The 2004 modeling agrees with these observations and shows that the flooding for that event is primarily located through the University, as well as some shallow flooding at the lower end of Makiki near the confluence with the Ala Wai Canal. The figures below show the approximated observed inundation through the University of Hawaii from the 2004 event and the 2004 inundation from the new 1D/2D HEC-RAS model for the 2004 event. The modeled inundation matches closely with the provided approximated flood extent. Unfortunately, no images could be found of the flooding along Makiki during the 2004 event but some personnel with the Honolulu District were aware of the flooding locations and were able to validate the inundations that were provided out of the model for the flooding on the lower Makiki Stream during the 2004 event. For the 2006 event it was known that there was some flooding near the Iolani School and around the golf course and the modeling shows that these are primarily the only areas that flooded for the 2006. Unfortunately, no estimated extents were provided and so the exact footprint of the inundation could not be compared. The only image provided for the 1967 flood event is difficult to discern all the flooding but it is clear that the waters exceeded the banks of the Ala Wai Canal and the modeling shows flooding around the canal. There were also reports of street flooding during the 1967 flood in Waikiki and the modeling shows shallow flooding through portions of Waikiki. Unfortunately, no highwater marks were found which would provide more validation towards the model inundation.

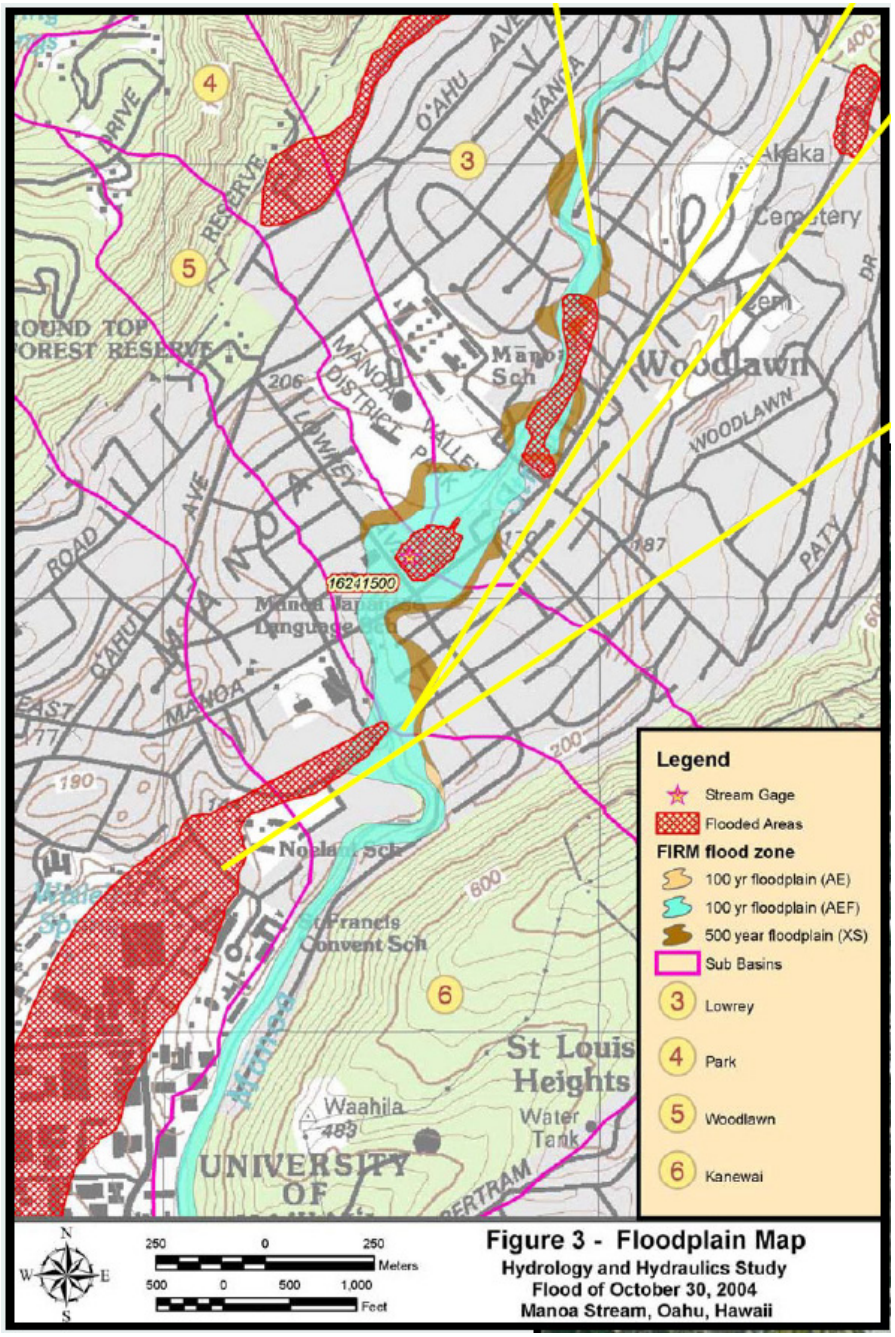

Figure 9: Approximate Flooding Extent from 2004 Event

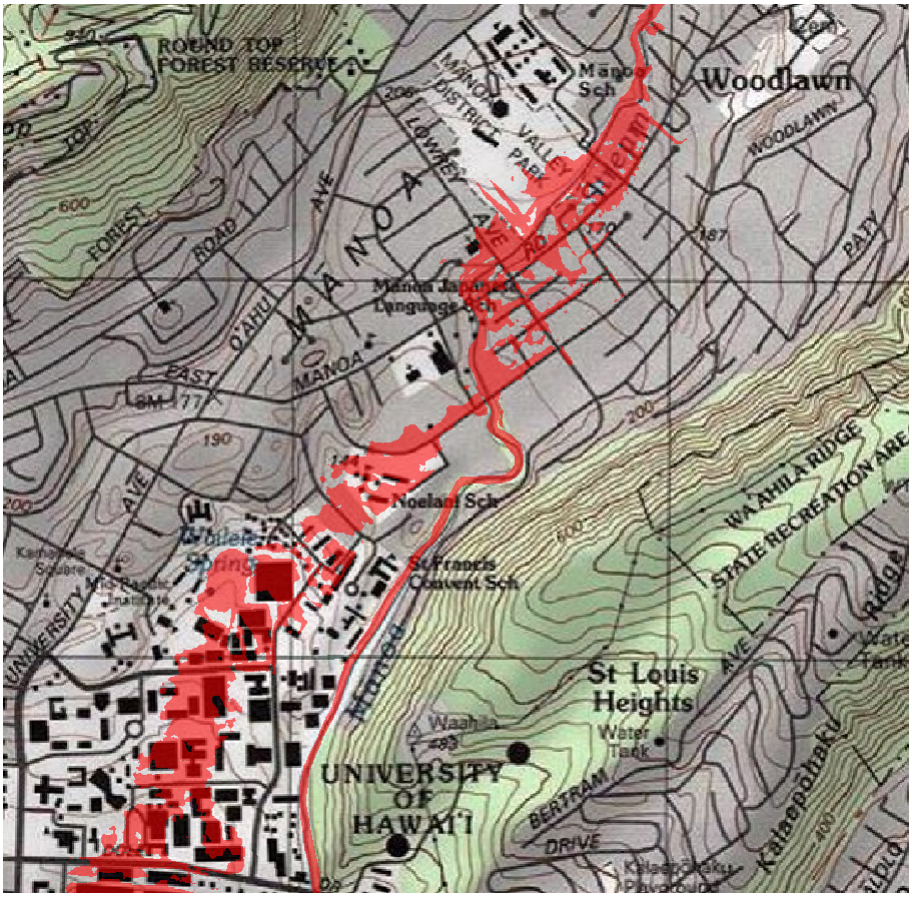

Figure 10: 2004 Flood Inundation with new HEC-RAS 1D/2D model

Figure 11: 2004 Flooding along the Ala Wai Canal during the 1967 flood

Overview – Without Project Scenario

The without project condition uses the same geometry as the calibration scenarios except the bridge at Woodlawn Drive and several cross-section below the bridge have been modified to account for improvements that have been made to the bridge and the excavation of the channel downstream of the bridge. These improvements were made within the last several years and occurred after all the calibration events. The improvements at Woodlawn Drive will reduce the WSEL around this area and would reduce the amount of flow leaving the channel at the Woodlawn Drive area which should reduce the amount of flooding through the University of Hawaii. Since the primary flooding of the 2004 flood event was at the University of Hawaii and was due to the restricted flow and debris at the Woodlawn, it would not be appropriate to use the improvements for the calibration events. During a November 2018 site visit, this area was still under construction but was eventually finished in time for the improvements to be added to the model. Unfortunately, due to the lack of instrumentation in the areas and observed data since the improvements were complete, the model could not be calibrated with the improvements. Using the 1967 event since it was a high flow event on the Manoa Stream but did not have the debris issue at Woodlawn Drive Bridge like the 2004 event, a sensitivity was performed to determine the potential impact of these improvements. With the improvements, the WSEL above the Woodlawn Bridge dropped a maximum of approximately 3 ft right at the upstream face of the bridge but increased the WSEL downstream of the bridge between approximately 0.5 to 1.0 ft due to the increase conveyance under the bridge. For the 1967 event, the Woodlawn Drive Bridge improvements allowed an additional approximately 1,000 cfs through the bridge. These impacts were seen on Manoa Stream downstream of the Woodlawn Drive bridge to the confluence with the Palolo Stream.

The table below shows a comparison of water surface elevations at select locations between the original model and the updated 1D/2D model. The updated model uses 2D areas in the overbanks and therefore does not have the University of Hawaii (UH Split) and south of the Kanaha Stream (Kanaha_Split) reaches. These reaches were 1D reaches that were added into overbank areas to simulate flow that has left the main channel and flowed along the overbank areas through the UH_Split and Kanaha_Split. There are no real channels that exist in these areas, but the reaches were added to simulate overland flow. These areas are being modeled with 2D areas and do not have similar locations to compare. It should also be noted that the inflows between the original model and updated 1D/2D model are different. The original model used steady state flows that were weighted using different methodologies which only produced a single peak flow and therefore could not be used for the 1D/2D model since it is an unsteady flow model. For the new 1D/2D model, HEC-HMS model results which routed Atlas 14 rainfall data were used. Unfortunately, in the table below, flow comparisons cannot be made between the original model and the new updated model due to the stark difference in how the overbank flows were modeled. For the 2D overbanks, it would be difficult to determine flows in the overbanks since the flow paths are not necessarily parallel to the channel.

The last column shows the difference between in the without project plan for the original feasibility 1D HEC-RAS model and the new 2020 1D/2D HEC-RAS model. A positive value indicates that the 2020 1D/2D model plan has a higher WSEL than the original 1D model. A negative indicates a reduction in WSEL with the 1D/2D model as compared to the original 1D model and a zero value indicates no change between the two models.

The comparison is for the 1% AEP event (100 year) using a basin average precipitation from Atlas 14. The final proposed features and without project conditions will be based on frequency flows developed using the Hydrologic Engineering Center's Watershed Assessment Tool (HEC-WAT). Details of the flows used in the post-feasibility study can be found in the Post-Feasibility Hydrology Report.

Cross sections correlating to the table above are presented in the figure below.

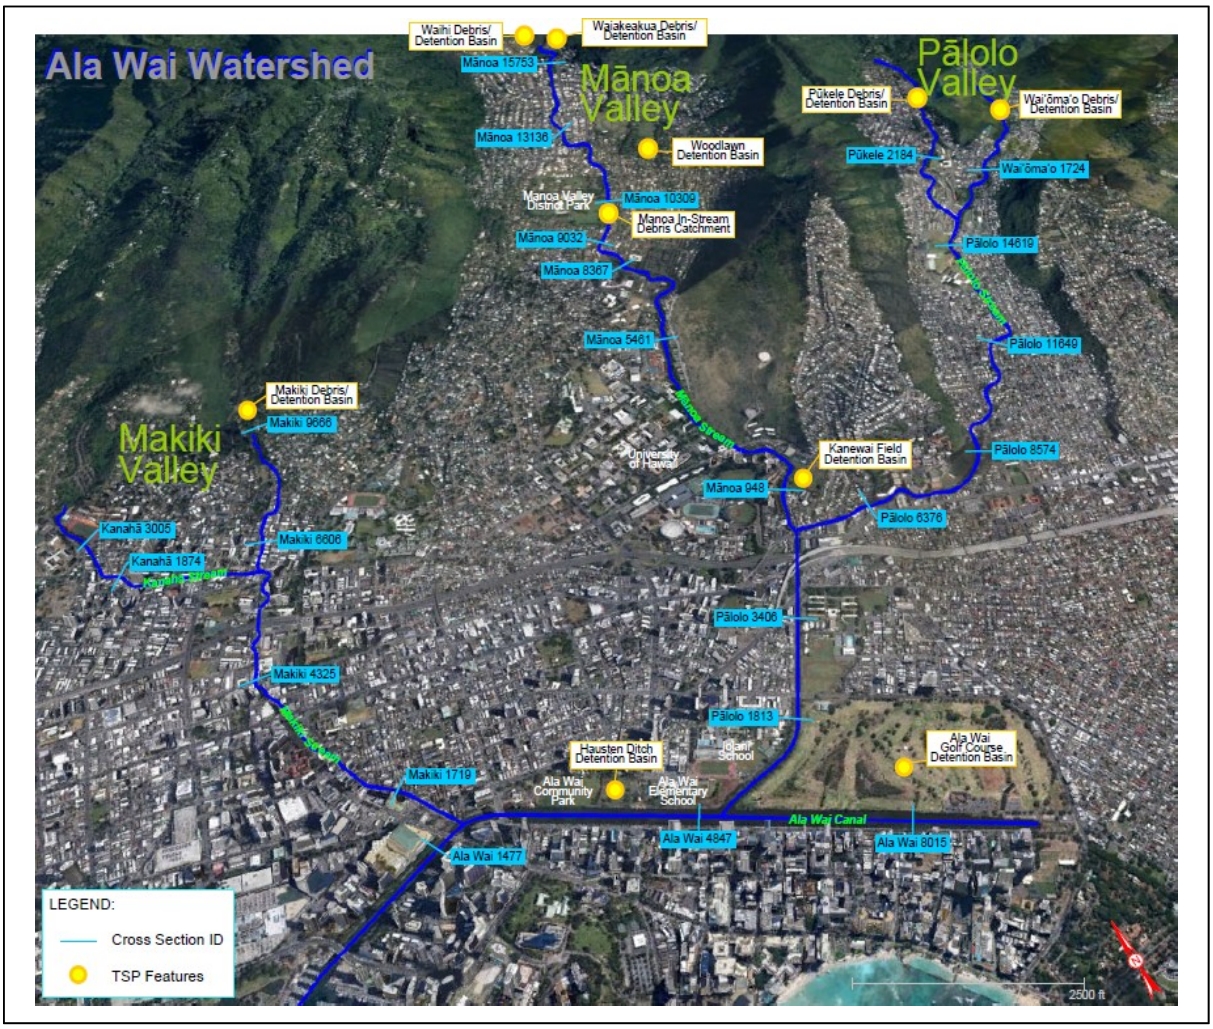

Figure 12: Cross-Section Locations

Sensitivity

To test the sensitivity of the model to the variation in Manning's "n" values, model runs were made for the without project conditions with the "n" values varying on average by +/- 20%.The range of roughness values was estimated at each location to determine a realistic high and low value for the area. The results show an average of 0.4 ft difference across the watershed for the 1% AEP. The average difference in the Ala Wai was approximately +/- 0.2 ft, for Makiki it was +/- 0.3 ft, Kanaha was +/- 0.2 ft, Manoa-Palolo Canal was +/- 0.3 ft, Manoa was +/- 0.5 ft, Palolo was +/- 0.3 ft, Pukele was +/- 0.5 ft, and Waiomao was +/- 0.4 ft. The largest differences were seen in areas with natural channels since these areas typically have a greater variability in estimated roughness depending on a person's judgment; whereas, areas that were concrete lined, the realistic values to use for this surface have less variability in estimates, so the variation in water levels were typically smaller. The figure below shows the difference in the inundation between the best estimate (green), high "n" values (red), and low "n" values (blue). The inundation is not significantly impacted by the change in the values. Most of the increased inundation is very shallow flooding.

Figure 13: Inundation Comparison from Manning's "n" Sensitivity Analysis

Project Phases

There were three phases to the Ala Wai Canal project, including the Feasibility phase, the Post-Feasibility Analysis, and the selection of the Proposed Final Features. The Feasibility study was completed in 2017 and is documented in *Ala Wai Canal Flood Risk Management Study O'ahu, Hawai'I Final Feasibility Study Report with integrated Environmental Impact Statement* Appendix A – Hydrology and Engineering (2017). The purpose of the Post-Feasibility study was to upgrade the steady 1D HEC-RAS model from the previous study with 2D areas and a switch to unsteady flow to improve the accuracy of the model. Once the model was updated and calibrated, the features from the tentatively selected plan (TSP) from the feasibility study were input into the model to determine their impacts to the 1% AEP (annual exceedance probability) flows. In addition, modifications to the features were evaluated to produce the most effective and optimal design for the watershed. After running multiple design considerations, a final proposed design was chosen and modeled. Other frequency events were modeled once all the features in the study were modified and optimized.

Project Features from the Feasibility Study

Overview

The figure below shows the Tentatively Selected Plan (TSP) features from the feasibility study.

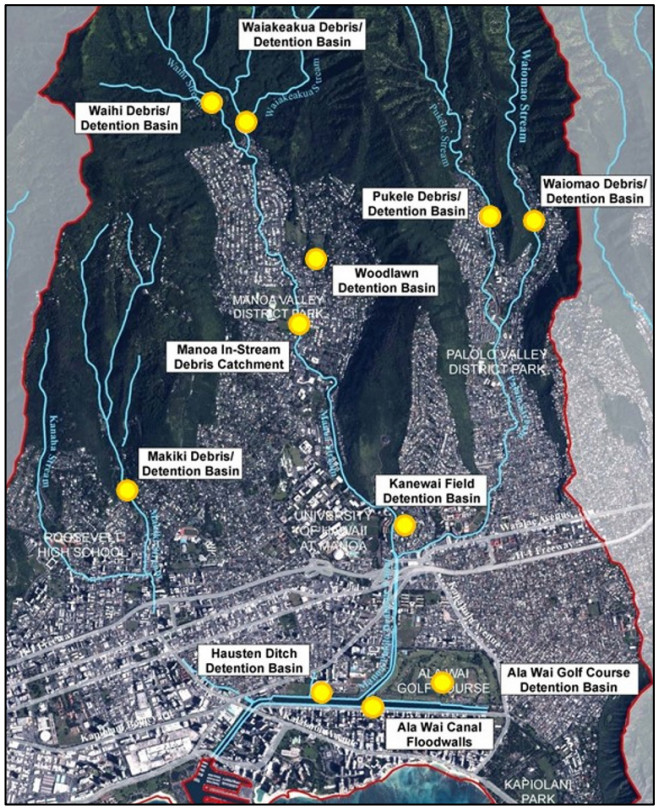

Figure 14: Recommended TSP Features

Project features from the feasibility study included the following eleven individual structural elements and two non-structural components as carried forward from the feasibility study:

- Floodwalls along Ala Wai Canal (including pump stations for interior drainage)
- Three multi-purpose detention basins
    - Ala Wai Canal Golf Course Multi-Purpose Detention
    - Hausten Ditch Detention
    - Kanewai Field Detention
- One stand-alone debris catchment structure
- Six debris/detention basins in upper stream reaches
    - Makiki Debris and Detention Basin
    - Waihi Debris and Detention Basin
    - Waiakeakua Debris and Detention Basin
    - Pukele Debris and Detention Basin
    - Waiomao Debris and Detention

Ala Wai Canal Floodwalls

The Ala Wai Canal Floodwall system was designed to keep the 1-percent AEP (100-year) flow within the existing channel with 90% Assurance. At the upstream end, the floodwall system will connect to the Ala Wai Golf Course Levee and run along the left bank of the Ala Wai Canal. There will be no floodwall on the right bank of the Canal next to the golf course. The floodwall system will continue to run along both banks all the way to the Ala Moana Blvd Bridge. The floodwall will also extend up the Makiki Stream along both banks to the Kapiolani Blvd Bridge. The figure below shows the TSP floodwall alignment.

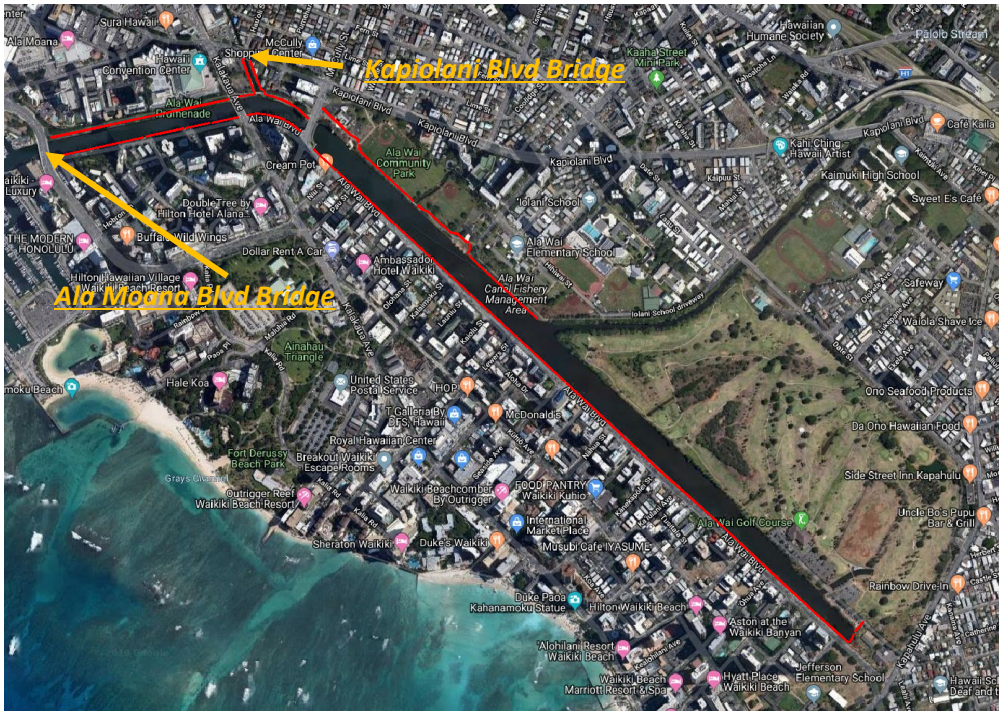

Figure 15: TSP Ala Wai Floodwall Alignment

Ala Wai Golf Course Multi-Purpose Detention

This multi-purpose detention basin was designed to contain water on the golf course and prevent flood waters from leaving. There will be earthen berms constructed on the north and east sides of the golf course, the berms will basically follow the existing golf cart road. The berms have an average height of 3 feet. The height of the berm was set to prevent overtopping from the flooding in the interior of the golf course during the 100-year design storm.

The Ala Wai Golf Course would act as a detention basin allowing flows from the Manoa-Palolo Drainage Canal would be diverted into the basin. Flows would reenter into the Canal at two locations, a new outlet connected to the basin and an existing outlet.

Figure 16: Ala Wai Golf Course TSP Berm Alignment

Hausten Ditch Detention

This basin is designed to temporarily contain water while the slide gates at Hausten Ditch Bridge are up. The slide gates will be down during a flood event to prevent water from Ala Wai Canal flowing back into Hausten Ditch. In addition, the basin is designed to use existing open space (i.e. no residential houses).

Figure 17: Hausten Ditch TSP Berm Alignment

Woodlawn Detention

The basin is not designed to permanently contain water, but to detain large volumes of water to slow the rate into Woodlawn Ditch will eventually flow into Manoa Stream. The design assumes an embankment elevation of 229.0 ft, a 100 ft long concrete-lined emergency spillway at elevation 226.0 ft, and a box culvert 5.25 ft wide by 7.5 ft high. The culvert is 110 ft long with an upstream invert elevation of 200.5 ft and a downstream invert elevation of 199.0 ft. No excavation was assumed, and any storage was based on LiDAR data.

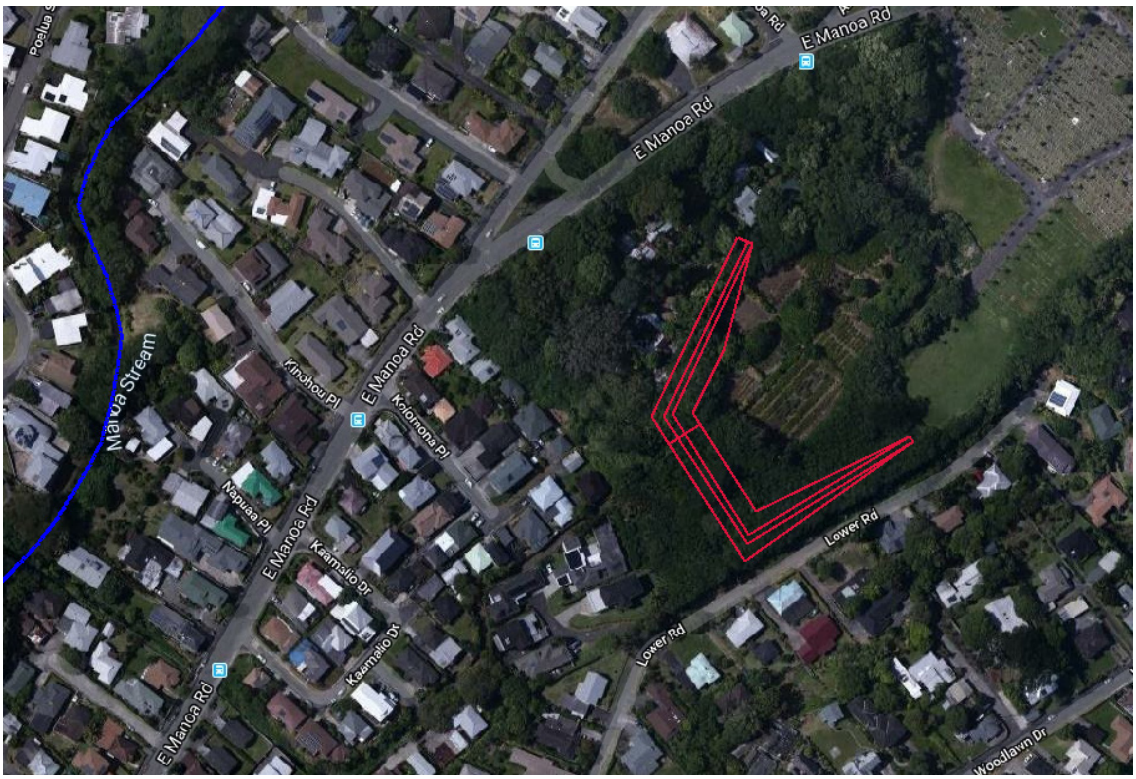

Figure 18: Woodlawn Ditch Detention TSP Dam Alignment

Manoa In-Stream Debris Catchment

This structure was designed to catch large debris. It allows all flood flows to pass through the debris poles. It was assumed that the largest river flow would be below the maximum height of the poles and will span the length of the debris catchment structure. The structure consists of a 2-foot thick concrete pad that spans 60 feet across the stream and the floodplain with a width of 8 feet. Steel posts 8 inches in diameter and between 4 to 7 feet high are evenly spaced at 4 feet along the center of the concrete pad.

Kanewai Field Detention

The basin is designed to use existing open space (park land) to temporarily contain floodwaters. The intake weir into Kanewai Field is intended to handle overflow from the Manoa Stream. The existing 2 ft drainage pipe can drain some of the water. Kanewai Field will be surrounded by a 7-foot-high earthen berm but protecting the existing structures. The berm will be built to an elevation of 43.0 ft. On the northwest end of the basin, adjacent to Manoa Stream, the berm is graded down to a 50 foot spillway that will allow water to flow into the basin when the river level is high and out of the basin once the high flows have passed. The spillway has a crest elevation of 38.0 ft. There is no estimated excavation of the site.

Figure 19: Kanewai Field Detention TSP Berm Alignment

Upstream Detention Basins

Overview

Five basin features, Makiki, Waihi, Waiakeakua, Pukele, and Waiomao, were designed for both debris and detention, and were in the upstream reaches of the system. Each basin was required to pass the 100-year design event without debris blocking the intake structure.

Makiki Debris and Detention Basin

This basin is designed as both a way to temporarily contain water and stop the flow of debris into Makiki Stream. The basin is not designed to permanently contain water, but to detain large volumes of water to slow the rate into Makiki Stream. In addition, the basin is designed to use existing open space (i.e. no residential houses). The design assumes an embankment elevation of 185.0 ft, a 60 ft long concrete-lined emergency spillway at elevation 180.8 ft, and an arch culvert 10.0 ft wide by 5 ft high. The culvert is 118 ft long with an upstream invert elevation of 164.0 ft and a downstream invert elevation of 162.0 ft.

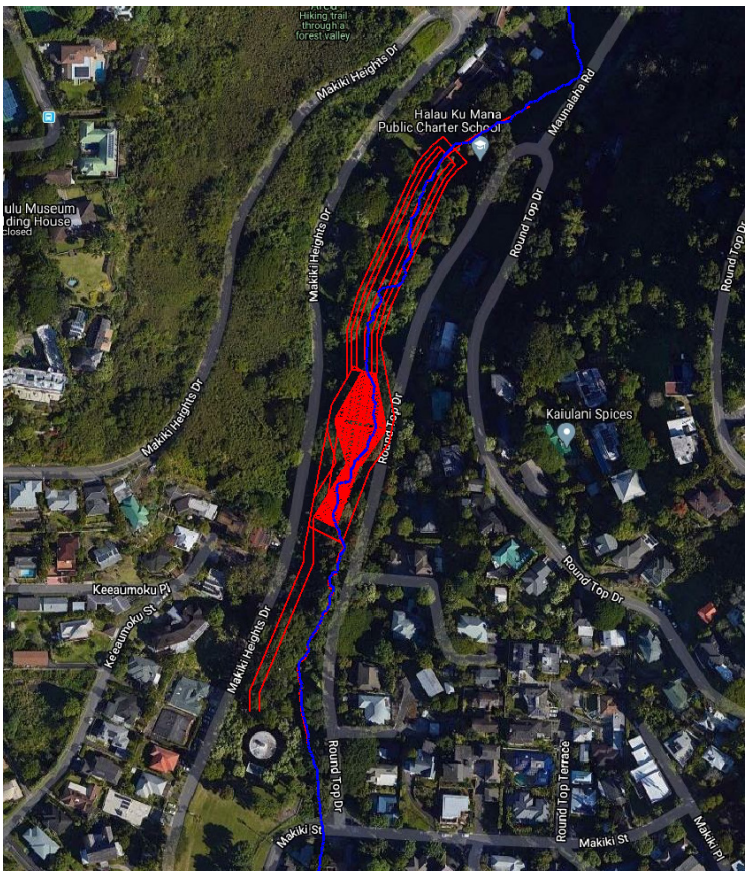

Figure 20: Makiki Detention TSP Berm Alignment

Waihi Debris and Detention Basin

This basin is designed as both a way to temporarily contain water and stop the flow of debris into the Manoa residential area. The basin is not designed to permanently contain water, but to detain large volumes of water to slow the rate into Manoa Stream. In addition, the structure is to not interfere with existing farms and houses near the basin site. The design assumes an embankment elevation of 404 ft, a concrete-lined emergency spillway at elevation 400.0 ft, and a box culvert 12.0 ft wide by 6 ft high. The culvert is 167 ft long with an upstream invert elevation of 375.0 ft and a downstream invert elevation of 366.0 ft. The figure below shows the approximate alignment of the Waihi Detention Basin Dam.

Figure 21: Waihi Detention TSP Berm Alignment

Waiakeakua Debris and Detention Basin

This basin is designed as both a way to temporarily contain water and stop the flow of debris into the Manoa residential area. The basin is not designed to permanently contain water, but to detain large volumes of water to slow the rate into Manoa Stream. In addition, the structure is to not interfere with existing farms and houses near the basin site. The design assumes an embankment elevation of 338 ft, a concrete-lined emergency spillway at elevation 334.0 ft, and an arch culvert 12.0 ft wide by 6 ft high. The culvert is 240 ft long with an upstream invert elevation of 294.0 ft and a downstream invert elevation of 284.0 ft. The figure below shows the approximate alignment of the Waiakeakua Detention Basin Dam.

Figure 22: Waiakeakua Detention TSP Berm Alignment

Pukele Debris and Detention Basin

This basin is designed as both a way to temporarily contain water and stop the flow of debris into Pukele Stream. The basin is not designed to permanently contain water, but to detain large volumes of water to slow the rate into Pukele Stream. The design assumes an embankment elevation of 441.0 ft, a 60 ft long concrete-lined emergency spillway at elevation 436.0 ft, and a box culvert 8.5 ft wide by 8 ft high. The culvert is 155 ft long with an upstream invert elevation of 414.3 ft and a downstream invert elevation of 408.0 ft. The figure below shows the approximate alignment of the Pukele Detention Basin Dam.

Figure 23: Pukele Detention TSP Berm Alignment

Waiomao Debris and Detention Basin

This basin is designed as both a way to temporarily contain water and stop the flow of debris into Waiomao Stream. The basin is not designed to permanently contain water, but to detain large volumes of water to slow the rate into Waiomao Stream. The design assumes an embankment elevation of 402.0 ft, a 100 ft long concrete-lined emergency spillway at elevation 398.0 ft, and a box culvert 8.75 ft wide by 8 ft high. The culvert is 230 ft long with an upstream invert elevation of 369.9 ft and a downstream invert elevation of 361.0 ft. The figure below shows the approximate alignment of the Waiomao Detention Basin Dam.

Figure 24: Waiomao Detention TSP Berm Alignment

Post-Feasibility Analysis

Tentatively Selected Plan (TSP)

The purpose of this study was to upgrade the HEC-RAS model from the previous study with 2D areas to improve the accuracy of the model. Once the model was updated and calibrated, the features from the tentatively selected plan (TSP) from the feasibility study were input into the model to determine their impacts to the 1% AEP flows. Other frequency events will be modeled once all the features in the study have been modified and optimized. The sections below describe the features that were modeled as part of the TSP from the feasibility study.

The figure below shows the Tentatively Selected Plan (TSP) features from the feasibility study.

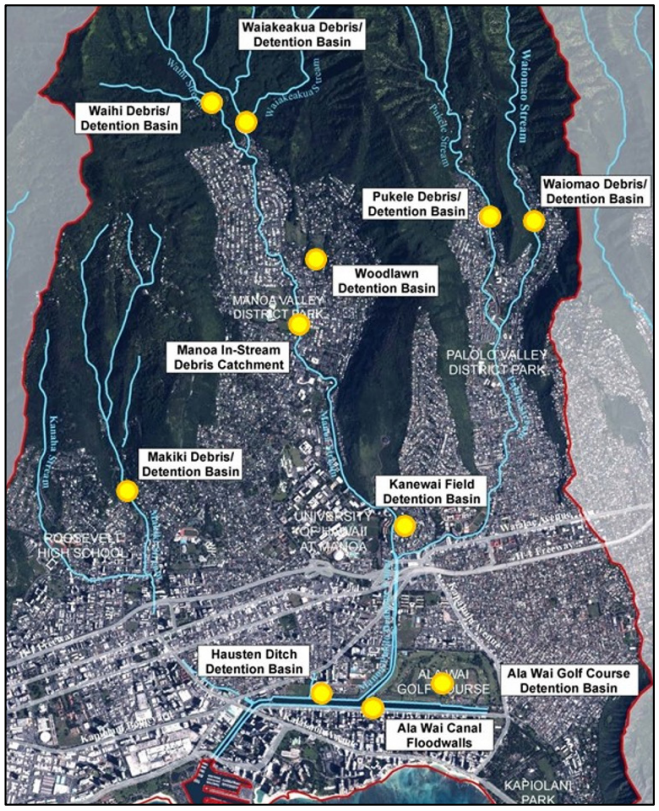

Figure 25: Recommended TSP Features

Project features from the feasibility study included the following eleven individual structural elements and two non-structural components as carried forward from the feasibility study:

- Floodwalls along Ala Wai Canal (including pump stations for interior drainage)
- Three multi-purpose detention basins
    - Ala Wai Canal Golf Course Multi-Purpose Detention
    - Hausten Ditch Detention
    - Kanewai Field Detention
- One stand-alone debris catchment structure
- Six debris/detention basins in upper stream reaches
    - Makiki Debris and Detention Basin
    - Waihi Debris and Detention Basin
    - Waiakeakua Debris and Detention Basin
    - Pukele Debris and Detention Basin
    - Waiomao Debris and Detention

The post-feasibility TSP incorporated all the features from the feasibility study, but some modifications were required to incorporate them into the new modeling and some designs were updated as part of the post-feasibility study. The sections below describe how these features were modeled in the updated 1D/2D HEC-RAS model and any modifications to the design of the structures since the feasibility study.

Ala Wai Canal Floodwalls

Although it was not part of the TSP floodwall plan, the floodwall for this study was extended up the Manoa-Palolo Canal on the right bank near the Kaimuki High School athletic fields. The floodwall extended up to Date St. It was determined quickly that without this floodwall extended up the Manoa-Palolo Canal, the floodwall on the right bank of the Ala Wai Canal that extends from the Manoa-Palolo Canal Confluence to McCully St would be flanked by floodwaters and the floodwall would be of no use.

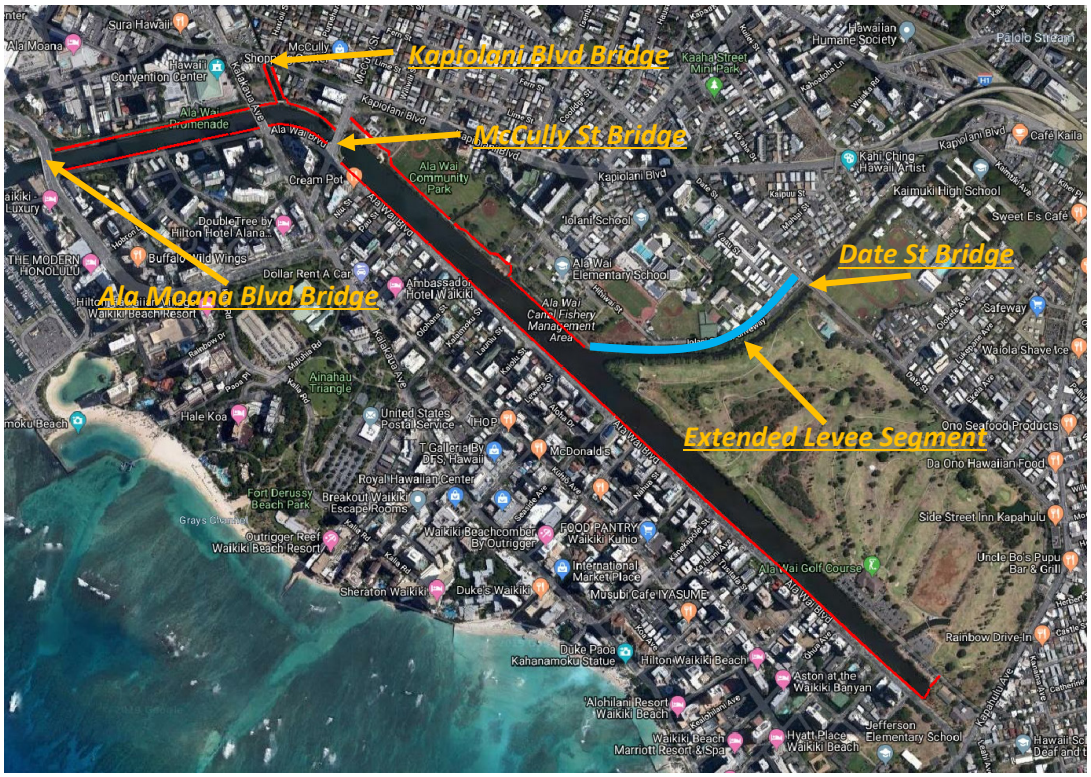

Figure 26: TSP Ala Wai Floodwall Alignment

The floodwalls were input as lateral structures in the model and used the elevations that were determined in the feasibility study. However, knowing that the WSEL would be subject to change due to the updates to the model, the weir coefficients were set to zero on the lateral structures representing the floodwalls. This was done to prevent flow from overtopping the levees if the WSEL was determined to be higher than the feasibility study. The elevations of the floodwalls could have been raised but it was decided to keep the original elevations so that design elevations could be compared with the new WSEL in the canal.

Ala Wai Golf Course Multi-Purpose Detention

The golf course berm design was the same as the feasibility study and was modeled as an internal hydraulic structure in the 2D flow area. The figure below shows the approximate alignment of the berm on the north and east side of the golf course.

Figure 27: Ala Wai Golf Course TSP Berm Alignment

Hausten Ditch Detention

The Hausten Ditch berm was modeled as an internal hydraulic structure in the 2D flow area. No gates were modeled since the gate would be closed during a flood. The figure below shows the approximate alignment of the berms of the Hausten Ditch Detention Basin.

Additionally, removing the floodwall on the canal front the Hausten Ditch area was also evaluated. Further consideration of the flood barrier alignment and effort to increase flood water detention, may be evaluated in future final layout designs of the system. The walls fronting the canal would be replaced with earthen berms along the sides and back perimeter of Hausten Ditch and the Ala Wai Community Park athletic fields to increase canal reservoir capacity. The flood gate originally proposed at the canal wall would be moved to the back perimeter of this detention area spanning Hausten Ditch. The realignment of the floodwall locations may be examined as part of the final design before construction.

Figure 28: Hausten Ditch TSP Berm Alignment

Woodlawn Detention

The structure was modeled as an internal hydraulic structure in the 2D flow area. It has two inflows into the Detention Basin. One inflow is from sub-basin M5 which drains into the detention and the other inflow is a diversion into the detention from an existing storm drain. This diversion flow comes from the sub-basin M6. The inflows were modeled in HEC-HMS. The figure below shows the approximate alignment of the Woodlawn Ditch Detention Dam.

Figure 29: Woodlawn Ditch Detention TSP Dam Alignment

Manoa In-Stream Debris Catchment

The Manoa in-stream debris catchment was modeled using the Bridge/Culvert feature in HEC-RAS. This feature in HEC-RAS allows for the placement of piers and can simulate floating debris. However, the feature does require a high chord and low chord to be input into the model. Since there will not be a bridge deck for this feature, the high chord and low chord were set artificially high so that these features will never have water on them. The bridge modeling approach used energy for both the high and low flow methods.

Since this structure is meant to catch debris during flood events, the floating debris was modeled for each steel post. There are no other structures like this in the area and as such there was no clear information on much debris blockage to assume. However, using judgment from the debris blockage on the Woodlawn Driver Bridge during the 2004 event, which is what this feature is designed to prevent, the debris blockage was assumed to be approximately 4 ft high and will be across the length of the structure. The figure below shows the structure in the model with the floating debris applied.

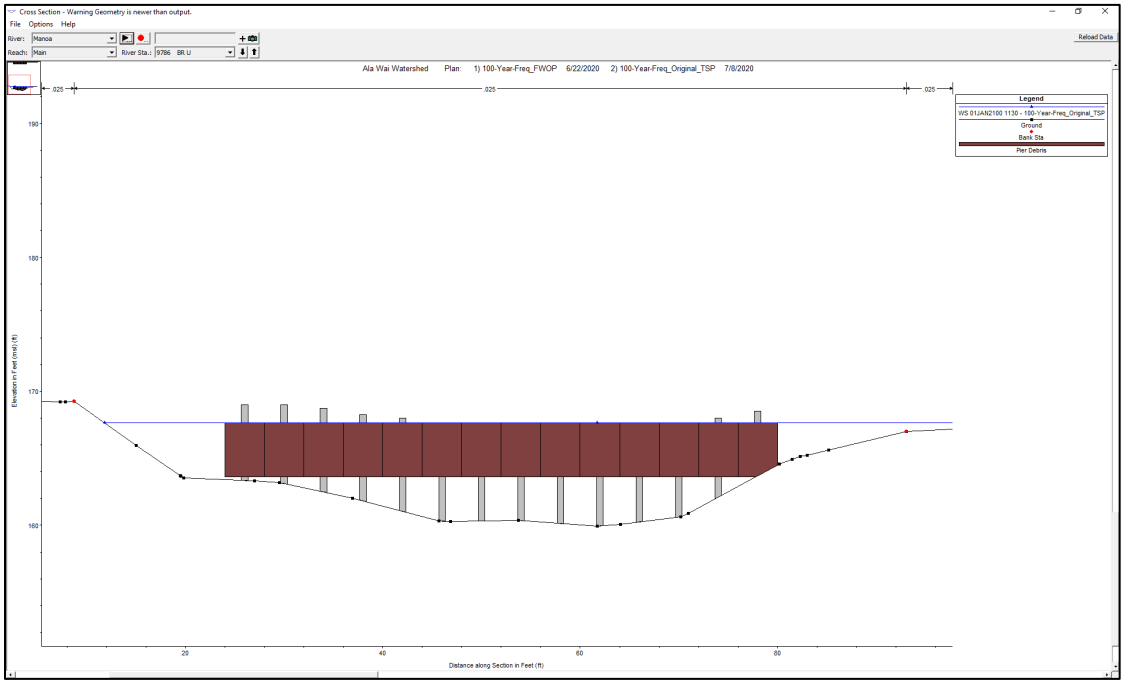

Figure 30: Manoa In-Stream Debris Catchment in HEC-RAS

Kanewai Field Detention

The berm was modeled as an internal hydraulic structure in the 2D flow area and the spillway was modeled as a lateral structure on the left bank of the Manoa Stream. The figure below shows the approximate alignment of the Kanewai Field Berm.

Figure 31: Kanewai Field Detention TSP Berm Alignment

Upstream Detention Basins

Overview

Five basin features, Makiki, Waihi, Waiakeakua, Pukele, and Waiomao, were designed for both debris and detention, and were in the upstream reaches of the system. At the beginning of this effort, it was determined that the excavation and dimensions for these structures were unrealistic due to topography and geology. So new excavation and dimensions were determined for this study to replace the original TSP designs.

Two teams, one based in the Seattle District and one based in the New Orleans District were also in the design process for the dams and pumps, respectively. The latest versions of dam data below were developed by the Seattle District and MMC Teams. The Seattle Design Team also provided updated estimated excavation for the pools of Makiki, Waihi, Waiakeakua, Pukele, and Waiomao.

Multiple variations of dam culvert, spillway, and storage were modeled to better understand the system response for each of the upstream dams. Initial excavation, spillway, and dam data for each iteration was provided by the Seattle Design Team. The excavation for Makiki, Pukele, and Waiomao were pulled into RAS Mapper and merged with updated LiDAR provided by the Hawaii District. Waihi and Waiakeakua were modeled in HEC-HMS rather HEC-RAS. The outflow from these two dams from HEC-HMS was input as an upstream flow hydrograph on the Manoa Reach in the HEC-RAS model. Reasonable culvert elevations and lengths were estimated from this terrain. A reasonable land area encompassing a given possible pool was analyzed to determine a unique Elevation-Volume curve, as shown below.

Makiki Debris and Detention Basin

During the post-feasibility study, it was quickly determined that due to topology and geology, the storage volume that was determined during the feasibility would have required significant excavation to achieve. Due to the topology, geology, and the expense required to achieve this storage volume, new storage volume excavation would need to be determined that would be feasible for this area and not cost prohibited. A reasonable excavation for the area was calculated by the Seattle District and the created terrain was imported into HEC-RAS. The detention basin lies in a narrow section of land between two roads, so the excavation is limited in this area. The new excavation was determined based on the topology and designed such that the slopes would be stable and would not require retaining walls to prevent collapse of the sidewalls. The structure was modeled as an inline structure with a 1D storage area. The maximum storage at the dam crest is approximately 14.0 acre-ft. The figure below shows the approximate alignment of the Makiki Detention Basin Dam.

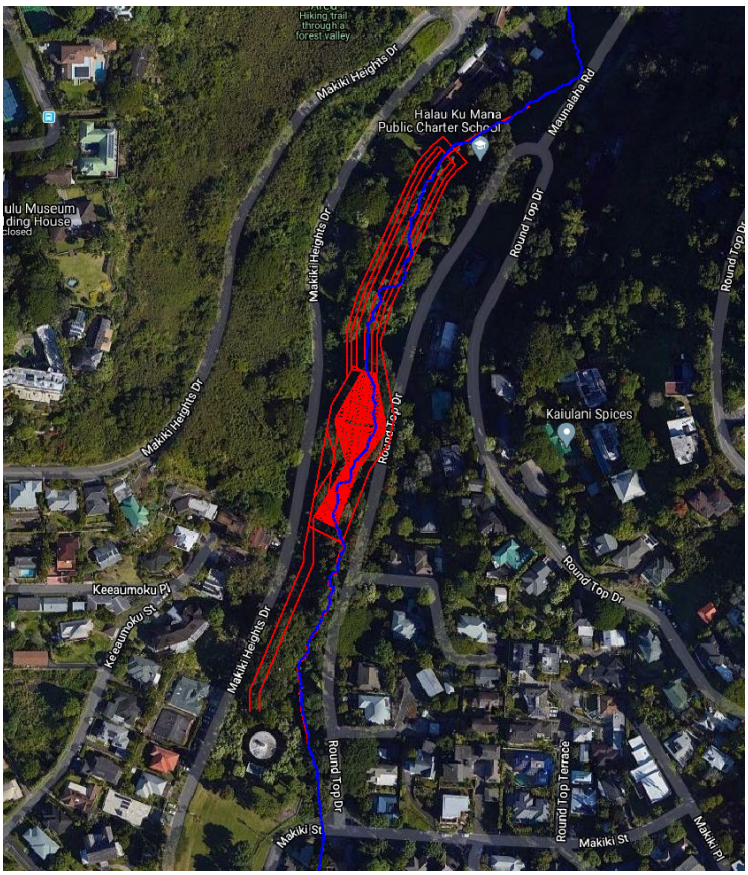

Figure 32: Makiki Detention TSP Berm Alignment

Waihi Debris and Detention Basin

Similar to Makiki Detention, it was determined during the post-feasibility study that due to topology and geology, the storage volume would need to be modified. Based on the topology and geology, a reasonable excavation and alignment was calculated by the Seattle District that would produce a stable detention basin that was not overly cost prohibited. Seattle district created a terrain surface for the new excavation, and this was used to estimate storage volumes. The structure is located above where the HEC-RAS model begins on Manoa Stream, so the HEC-HMS model was used to compute the flows for the structure along with the nearby structure of Waiakeakua. The outflow from these two structures were modeled as a junction since the flows will combine as they enter Manoa Stream just upstream of where the HEC-RAS model begins. The outflow from this junction in HEC-HMS was used as the upstream inflow into the HEC-RAS model. Further information of these structures can be found in the Hydrology Report. The figure below shows the approximate alignment of the Waihi Detention Basin Dam.

Figure 33: Waihi Detention TSP Berm Alignment

Waiakeakua Debris and Detention Basin

Similar to Waihi Detention, it was determined during the post-feasibility study that due to topology and geology, the storage volume would need to be modified. Based on the topology and geology, a reasonable excavation and alignment was calculated by the Seattle District that would produce a stable detention basin that was not overly cost prohibited. Seattle district created a terrain surface for the new excavation, and this was used to estimate storage volumes. The structure is located above where the HEC-RAS model begins on Manoa Stream, so the HEC-HMS model was used to compute the flows for the structure along with the nearby structure of Waihi. The outflow from these two structures were modeled as a junction since the flows will combine as they enter Manoa Stream just upstream of where the HEC-RAS model begins. The outflow from this junction in HEC-HMS was used as the upstream inflow into the HEC-RAS model. Further information of these structures can be found in the Hydrology Report. The figure below shows the approximate alignment of the Waiakeakua Detention Basin Dam.

Figure 34: Waiakeakua Detention TSP Berm Alignment

Pukele Debris and Detention Basin

Similar to the Makiki and Manoa Stream detention basins, it was determined during the post-feasibility study that due to topology and geology, the storage volume would need to be modified. A reasonable excavation was calculated by the Seattle District and the created terrain was imported into HEC-RAS. The detention basin lies in a narrow section of land and is limited by residential areas, so the excavation is limited in this area. The structure was modeled as an inline structure with cross-sections used to model reservoir. The cross-sections were extracted from the new terrain created by the Seattle District. The maximum storage at the dam crest is approximately 15.0 acre-ft. The figure below shows the approximate alignment of the Pukele Detention Basin Dam.

Figure 35: Pukele Detention TSP Berm Alignment

Waiomao Debris and Detention Basin

Similar to the other 5 detention basins it was determined during the post-feasibility study that due to topology and geology, the storage volume would need to be modified. A reasonable excavation was calculated by the Seattle District and the created terrain was imported into HEC-RAS. The structure was modeled as an inline structure with cross-sections used to model reservoir. The cross-sections were extracted from the new terrain created by the Seattle District. The maximum storage at the dam crest is approximately 35.0 acre-ft. The figure below shows the approximate alignment of the Waiomao Detention Basin Dam.

Figure 36: Waiomao Detention TSP Berm Alignment

Results of Post-Feasibility TSP and Without Project Comparison

The table below shows a comparison of water surface elevations at select locations between the without project conditions and the TSP features from the feasibility study which includes Post-Feasibility modifications to represent more realistic dimensions and storage. The last column shows the difference between the post-feasibility TSP plan and the without project plan. A positive value indicates that the TSP plan has a higher WSEL than the without project conditions. The Ala Wai Canal and the areas of the other streams near the confluence with the Ala Wai Canal are higher in the TSP plan compared to the without project plan because the floodwalls are containing the floodwaters that would have otherwise been in the overbanks. A negative indicates a reduction in WSEL with the TSP in place as compared to the without project conditions and a zero value indicates no change between the with and without project features.

The comparison is for the 1% AEP event (100 year) using a basin average precipitation from Atlas 14. The final proposed features and without project conditions will be based on frequency flows developed using the Hydrologic Engineering Center's Watershed Assessment Tool (HEC-WAT). Details of the flows used in the post-feasibility study can be found in the Post-Feasibility Hydrology Report.

Table 11: WSEL Comparisons at Select Locations between Without Project Conditions and the TSP Features

Reach Name (per HEC-RAS Model)	Cross-Section ID		1% AEP Event (100 year)		Difference (TSP – W/out) (ft)
	New 1D/2D Model	Location Description	Without Projects WSEL (ft)	With TSP Features WSEL (ft)

*Difference is due to the cross-section being in the Makiki Detention Basin pool for the TSP plan.

Below is a figure illustrating the differences in the inundation between the without project conditions (red) and with TSP project conditions (blue).

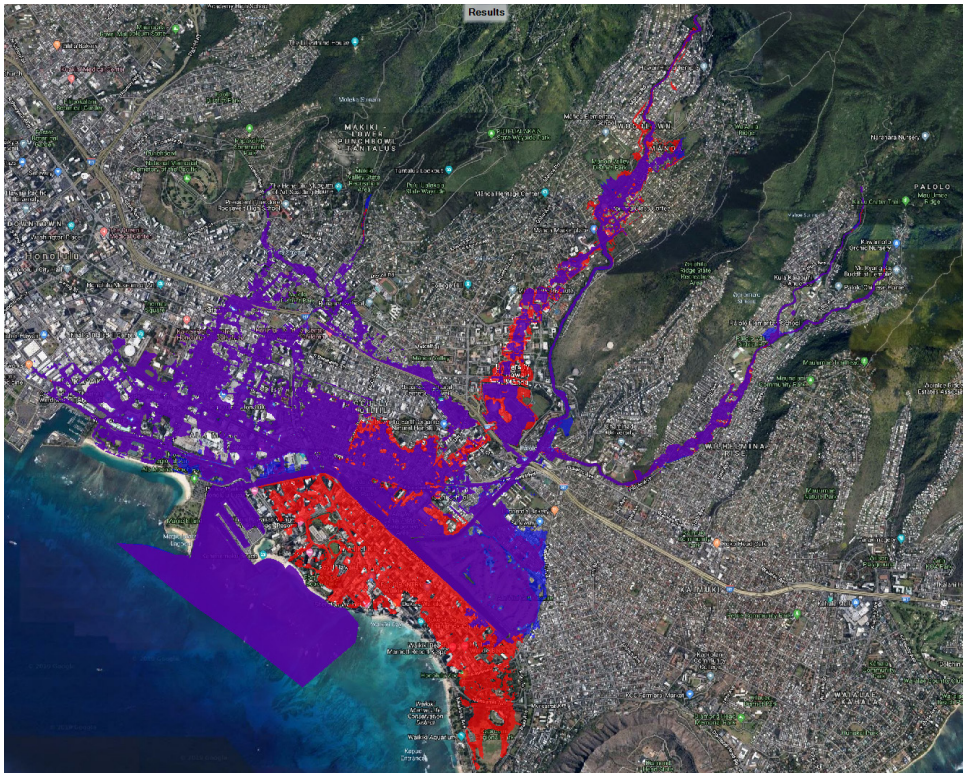

Figure 37: Inundation of Without Project (red) and With TSP Projects (blue)

Ala Wai Canal

The results from the table above show that the Ala Wai Canal increased up to 2 ft in places, but this is expected. The placement of floodwalls in the area are preventing the water from storing in the overbanks and that volume is expected to go down the Ala Wai Canal which increases the WSEL along the canal. The figure of the inundation shows that the inundation has been greatly reduced in the Waikiki area and to the north of the Canal. However, it also shows that the TSP is inducing flooding north and northeast of the Ala Wai Golf course. This is due to the new berm placed on the north end of the golf course. The berm is preventing flow from traveling south into the golf course and so it is flooding more areas north of the golf course as the flow pushes east instead of south. There is also some induced flooding along the right embankment of the Ala Wai Canal below the confluence with Makiki Stream. This flooding is due to the higher water levels in the Canal that are backing up the Makiki Stream. In addition, the floodwall on the right bank below the confluence is preventing the excess flows

from flowing back into the canal. In sections below, additional modifications were tested to prevent this induced flooding.

Makiki

The results from the table above show that the Makiki Detention Basin provided little to no protection. The structure on Makiki was determined to be ineffective due to the limited storage capacity that could be reasonably excavated. There was no way to realistically excavate the original storage volume from the feasibility study without an exorbitant cost due to the narrow valley, the detention basin would have to have a significant depth to achieve the storage volume. This would have required extremely tall vertical walls on either side of the valley and would have to be shored up and reinforced to prevent the roads on either side from collapsing into the detention basin. As a result of the reduction in storage volume, the post-feasibility TSP design only reduces the 1% AEP flow by approximately 5 cfs. In addition, it was found that significant attenuation behind downstream bridges of the watershed negated the effects of the reduced peak flow. In sections below, additional modifications were tested for this reach. This feature was ultimately removed from the Proposed Final Feature design.

Manoa

The results from the table above show that Waihi and Waiakeakua reduced the water levels downstream of the structures by approximately 1 ft but this is in an area that is mostly contained in the channel on the upstream end of the Manoa Watershed, so it provides little benefit. By the time the floodwaters reach Manoa Park, the reduction in water level is only about 0.5 ft. It was found that significant attenuation behind downstream bridges of the watershed negated the effects of the reduced peak flow. The Woodlawn Detention was found to have little effect on the water levels due to the limited storage capacity and the relatively small sub-basin catchment area compared to the rest of the Manoa Watershed. The results do show a significant reduction in water levels near East Manoa Bridge and near the Manoa Marketplace. However, these reductions are believed to be heavily influenced by the Manoa In-Stream Debris Catchment upstream of East Manoa Bridge because the simulated floating debris is acting as a dam and reducing the flow downstream while increasing the water levels upstream and inducing additional flooding. In addition, the post-feasibility TSP scenario does not include debris on the Woodlawn Drive bridge due to the Manoa In-Stream Debris Catchment upstream of the bridge which was designed to catch the debris before it reaches the bridge so the bridge openings will not be clogged with debris. has increased the capacity of flow through the Woodlawn Drive Bridge and this most likely caused most of the reduction to the flooding through the University of Hawaii when compared to the effects of Waihi, Waiakeakua, and Woodlawn Detention. This also explains the higher water levels below Woodlawn Drive at St. Francis and Kanewai. Woodlawn Drive Bridge can now pass more flow and so the flow and water levels are increased downstream. In sections below, additional modifications were tested for this reach. Waihi, Waiakeakua and Woodlawn Detention basins were ultimately removed from the Proposed Final Feature design.

Palolo

The results from the table above show that both the Pukele Detention Basin and Waiomao Detention Basin provided little protection. The structures were determined to be ineffective due to the limited storage capacity that could be reasonably excavated. The Pukele Detention Basin only reduced water levels just downstream of the structure by 0.1 ft and Waiomao Detention Basin only reduced water

levels by 0.2 ft just downstream of the structure. In addition, it was found that significant attenuation behind downstream bridges of the watershed negated the effects of the reduced peak flow. In sections below, additional modifications were tested to prevent this induced flooding. Pukele and Waiomao detention basins were ultimately removed from the Proposed Final Feature design.

Modifications to TSP Features

Overview

Due to changes in structure dimensions, storage excavations, and the additional insight that significant attenuation behind downstream bridges of the watershed negated the effects of the reduced peak flow from some structures, it was decided that additional modifications to the TSP plan should be evaluated. In total, 16 different scenarios were setup in the HEC-RAS model with different combinations of features and modifications. Since some features will be independent of other features, multiple modifications were included in some scenarios. For example, modifications on the Makiki Stream will not impact modifications on Manoa Stream or the Palolo Stream. So, 1 scenario could have different modifications in each stream. The table below shows the different features that were used for each scenario and the sections below describe any modifications that were made to the post-feasibility design or any new features that were added

Table 12: Modification Plan Features

Scenario Number	Makiki Debris and Detention Basin	Waihi Debris and Detention Basin	Waiakeakua Debris and Detention Basin	Manoa In-stream Debris Catchment	Manoa District Park Detention Basin	Woodlawn Ditch Detention	Woodlawn Bridge By-Pass	Kanewai Field Detention Basin	Pukele Debris and Detention Basin	Waiomao Debris and Detention Basin	Ala Wai Flood Walls	Golf Course Berm

	HEC-RAS Modeling
	HEC-HMS only, or HEC-HMS and HEC-RAS Modeling

Makiki Modifications

Since the TSP Makiki Detention Basin only reduces the water level by a maximum of approximately 0.2 ft just downstream of the structure and only reduces the peak discharge by 5 cfs, other modifications to the Makiki Detention were evaluated. As seen table 11 above, 3 modifications were evaluated. The modifications included replacing and relocating the planned single basin with two detention basins upslope in Kaneolole (right bank) and Moleka (left bank) headwater streams. Out of the options considered, the most viable and effective alternative in reducing WSE was the construction of two detention basins upslope in the headwater streams but it would come at a significantly increased cost. Modification 1 includes only the left bank detention, Modification 2 includes just the right bank detention, and modification 3 includes both detentions. Since these structures were above the HEC-RAS model extent, the different detention basins were modeled in HEC-HMS and outflows from these structures were imported into the HEC-RAS model. Additional information on these features can be found in the Hydrology Report. The table below shows the results of these runs compared with the option of not building a detention basin (i.e. Modification 4).

Table 13: WSEL Comparisons at Select Locations for Makiki Detention Basin Modifications

Reach Name (per HEC-RAS Model)	Cross-Section ID		1% AEP Event (100 year)				
	New 1D/2D Model	Location Description	Post-Feasibility TSP	Modification 1 – Left Bank Detention	Modification 2 – Right Bank Detention	Modification 3 – Both Banks Detention	Modification 4 – No Detention
			WSEL (ft)	WSEL (ft)	WSEL (ft)	WSEL (ft)	WSEL (ft)
Makiki Lower	1667	Fern	12.3	12.31	12.31	12.3	12.31
	4301	Beretania	38.68	38.83	38.76	38.62	38.91
Makiki Upper	6606	Wilder	70.02	69.82	69.54	69.31	70.2
	9271	Just Downstream of Detention Basin	159.57	159.4	159.2	159.04	159.6

Based on the results, the new modifications did provide some additional benefit when compared to the TSP, but the benefits were marginally better. Having both detention basins on the left and right bank reduced the water levels by up to 0.7 ft but as seen in the image below, the inundation is only marginally better and due to the cost of the structure and these small benefits, any project on Makiki was deemed to not be feasible.

Figure 38: Inundation of Without Projects (red) and with Both Left and Right Bank Detention Basins (blue)

Manoa Modifications

To reduce the inundation along the Manoa Stream, especially on the upstream portion of the basin, several modifications were evaluated across several structures. This included modifications to the Waihi and Waiakeakua, including a detention basin in the Manoa Park and a bypass inlet/culvert around Woodlawn Drive Bridge.

Waihi and Waiakeakua Modifications

An option to include automated gates on both Waihi and Waiakeakua was evaluated to see if a gated structure could more efficiently reduce the flows. A separate simplified 1D HEC-RAS model was created just for the structure and included just enough cross-sections downstream to compute an outflow.

Waihi Detention Basin was slightly modified from the TSP design. The design assumes the same embankment elevation of 404 ft, a concrete-lined emergency spillway 100 ft wide but the spillway elevation was raised to 402.0 ft from the original design of 400 ft, and the box culvert was replaced with a 13 ft wide by 8 ft high gate with an invert set to elevation 376.0 ft. The operation was set to release a max of 1,610 cfs.

Waiakeakua Detention Basin was slightly modified from the TSP design. The design assumes the same embankment elevation of 338 ft, a concrete-lined emergency spillway 80 ft wide but the elevation was raised to 338.0 ft, and the box culvert was replaced with a 7 ft wide by 7 ft high gate with an invert set to elevation 294.0 ft. The operation was set to release a max of 900 cfs.

The outflow hydrographs were combined and input into the upstream end of the HEC-RAS model for Manoa Stream. The peak outflow with the gates was approximately 2,500 cfs compared with the TSP which had a peak flow of approximately 3,500 cfs. The without project has a peak flow of approximately 4,600 cfs. The table below shows a comparison of water levels on the upper Manoa watershed. Modification 1 includes the TSP operation, Modification 3 includes the automatic gates, and without projects assumes no structures. All three of these scenarios do not include any other features along the Manoa Stream except for the Manoa In-Stream Debris Catchment and the removal of debris on Woodlawn Dr Bridge is included in the Modification 1 and 3 scenarios. The Woodlawn Detention basin was removed from both scenarios.

Table 14: WSEL Comparisons at Select Locations for Waihi & Waiakeakua Detention Basin Modifications

Reach Name (per HEC-RAS Model)	Cross-Section ID		1% AEP Event (100 year)		
	New 1D/2D Model	Location Description	Modification 1 – TSP	Modification 3 – Automated Gates	Without Projects
			WSEL (ft)	WSEL (ft)	WSEL (ft)
Manoa Main	948	Kanewai	38.8	38.82	N/A
	5461	St. Francis	116.93	116.67	N/A
	8367	Manoa Marketplace	154.03	153.72	N/A
	9032	E. Manoa Rd Bridge	159.79	158.88	N/A
	10309	Manoa Park	174.01	173.77	174.50
	13136	Poelua St.	209.78	208.8	211.05
	15753	Pawale Pl.	260.59	259.38	261.85

The results show that although there is a reasonable drop in the WSEL just below the dams (approximately 2.5 ft) using automated gates when compared to the without project features, the difference reduces to approximately 0.7 ft at Manoa Park. It has been found that the bridges along the stream have contributed to the attenuation of the flood waters. Below Manoa Park on Modifications 1 and 3 include the Manoa In-Stream Debris Catchment which acts as a small dam with the floating debris applied and the debris has been removed at the Woodlawn Drive Bridge, so it is difficult to make a direct comparison with the without project conditions below Manoa Park. However, when comparing the difference between the TSP and the automated gates for the detention basins, the differences start to converge as you move downstream. In addition, as can be seen in the figure below there is little difference in the inundation when compared between the TSP and the automated gates. Also, due to the complex nature of the gates, the additional expense, the maintenance, and the potential for the system not working when needed, the automated gates were removed from consideration, especially given limited gains from using these gates.

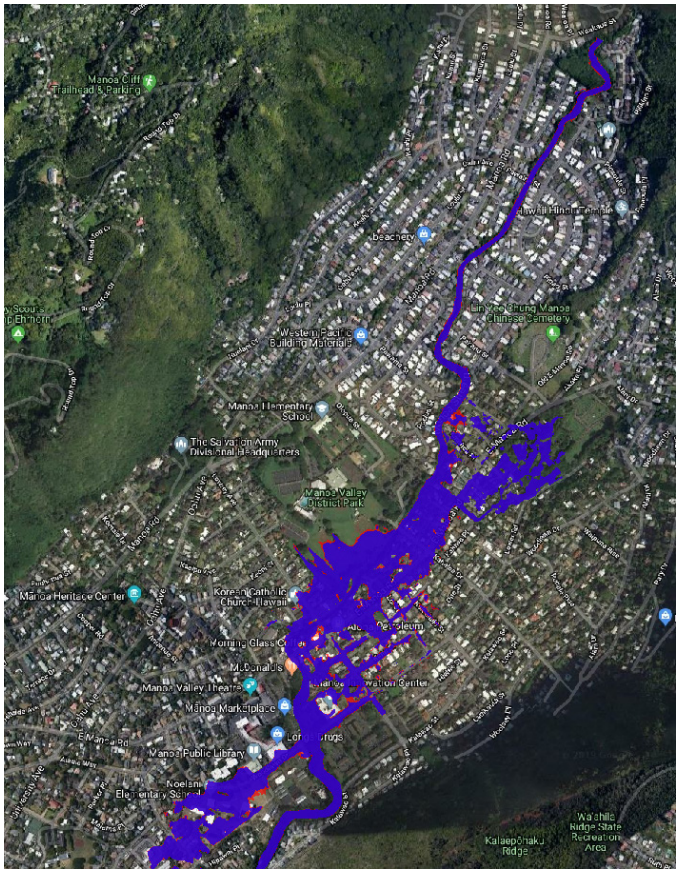

Figure 39: Inundation of TSP (red) and Automated Gates (blue) for Waihi and Waiakeakua Detention Basins

Manoa District Park Detention Basin

Since Waihi and Waiakeakua appear to provide limited benefits in reduction of flooding both in the Upper Manoa Basin and through the University of Hawaii due to attenuation of the flood waters on some of the downstream bridges, the Manoa Park Detention was evaluated. This detention basin was originally studied in the feasibility study but was not selected as part of the TSP. However, since the modeling has been updated to include 2D and unsteady flow, it was decided to re-evaluate the detention basin since it will be located downstream of some of the bridges.

The design of the Manoa Park Detention Basin includes a berm at elevation 180 ft that extends on the south and east sides of the park. The figure below shows the approximate alignment. Water enters the detention by a 20 ft wide by 10 ft high culvert that is placed upstream on the Manoa Stream approximately 300 ft upstream of Kahaloa Dr Bridge. The culvert is approximately 775 ft long. In addition, 2 culverts are placed in the berm to allow for drainage back into Manoa Stream. One culvert is a 2 ft diameter culvert located on the east side of the berm and ties into an existing ditch between the baseball fields. There is also a 4 ft by 4 ft box culvert located on the southeast corner of the berm and drains into a ditch on the southern part of the park. The berm is modeled as an internal hydraulic structure within the 2D area and includes the two drainage culverts. The inlet culvert is connected to the right bank lateral structure on the Manoa Main reach and connects via GIS coordinates to a cell in the 2D area.

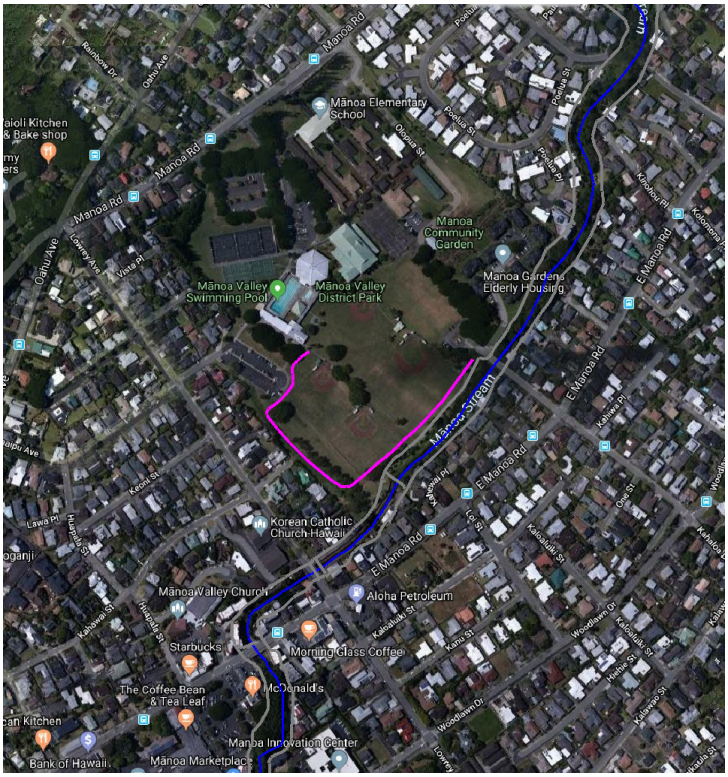

Figure 40: Manoa Park Detention TSP Berm Alignment

For comparison of the effectiveness of the structure, modification 12 was run with the Waihi and Waiakeakua TSP structures in place upstream and modification 16 includes no upstream structures. Both modifications include the Woodlawn Bypass which is located near the Woodlawn Dr Bridge. The table below shows the results for the Manoa Park Detention. For a comparison of the effectiveness between Waihi and Waiakeakua versus Manoa Park, modification 10 was included in the table because it represents Waihi and Waiakeakua with their TSP design but no Manoa Park.

Table 15: WSEL Comparisons at Select Locations for the Manoa Park Detention Basin Modifications

Reach Name (per HEC-RAS Model)	Cross-Section ID		1% AEP Event (100 year)		
			Manoa Park Detention		No Manoa Park
	New 1D/2D Model	Location Description	Modification 12 – Waihi & Waiakeakua TSP Design Upstream	Modification 16 – No Waihi or Waiakeakua Detention Upstream	Modification 10 - Waihi & Waiakeakua TSP Design
			WSEL (ft)	WSEL (ft)	WSEL (ft)
Manoa Main	948	Kanewai	38.69	39.45	39.6
	5461	St. Francis	116.7	117.56	117.9
	8367	Manoa Marketplace	153.19	153.74	154.13
	9032	E. Manoa Rd Bridge	157.93	158.7	160.26
	10309	Manoa Park	173.95	174.42	174.19
	13136	Poelua St.	210.2	211.07	210.19
	15753	Pawale Pl.	260.72	261.87	260.72

Based on the comparisons above, having both Waihi and Waiakeakua Detention and the Manoa Park (i.e. Modification 12) reduces the water surface on average approximately 0.5 ft between Manoa Park and Kanewai when compared to just Manoa Park only (i.e. Modification 16). Due to the expense of the structures, it would not be feasible to build all 3 structures for an average of 0.5 ft reduction. However, if you compare the Manoa Park only option (i.e. Modification 16) and Waihi & Waiakeakua only option (i.e. Modification 10), the Manoa Park appears to provide a greater reduction in water level when compared to Waihi & Waiakeakua detention. The Manoa Park Detention reduces the water level around the E. Manoa Rd Bridge by an addition 1.5 ft but due to the attenuation of the downstream bridges, this reduction is quickly reduced to only 0.4 within about 700 ft downstream. However, if you look at the figure below comparing the inundation between the Manoa Park Detention only versus the Waihi and Waiakeakua Detention only, the Manoa Park Detention causes more flooding. Some of the additional flooding is within the park which is part of the design but there is some additional flooding on the right bank above Manoa Park since the Manoa Park Detention will have more flow upstream of the detention basin. In addition, the berm is being flanked on the western edge for the 1% AEP which also leads to some additional flooding on the right bank downstream of the Manoa Park Detention.

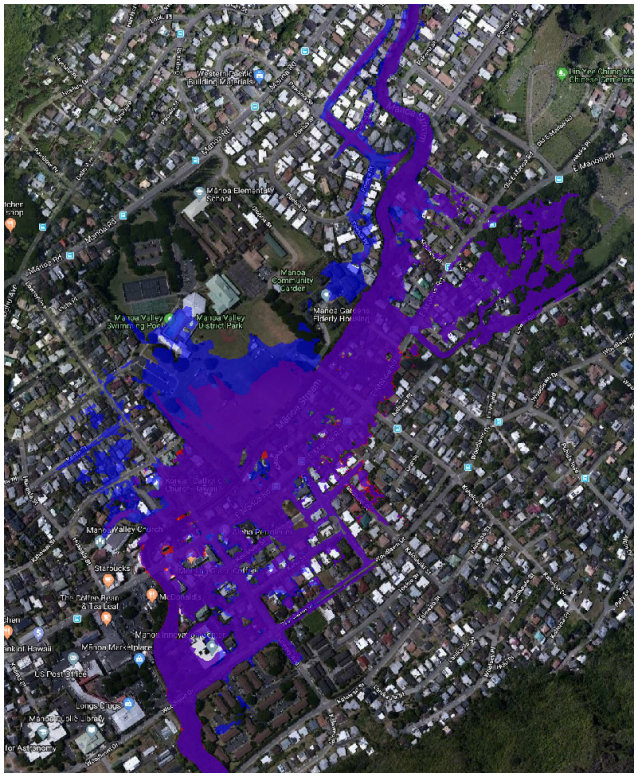

Figure 41: Manoa Park Detention only (blue) versus Waihi/Waiakeakua TSP Detention (red)

Woodlawn Detention

Although no modifications were made to the Woodlawn Detention Basin, two scenarios were run comparing the effectiveness of the structure. Modification 2 includes the Woodlawn Detention Basin and Modification 3 is the same as Modification 2 except the Woodlawn Detention Basin has been removed. The table below shows the results of those two scenarios.

Table 16: WSEL Comparisons at Select Locations for with and without the Woodlawn Detention Basin

Reach Name (per HEC-RAS Model)	Cross-Section ID		1% AEP Event (100 year)	
	New 1D/2D Model	Location Description	Modification 2 – with Woodlawn Detention Basin	Modification 3 – No Woodlawn Detention Basin
			WSEL (ft)	WSEL (ft)
Manoa Main	948	Kanewai	38.7	38.82
	5461	St. Francis	116.51	116.67
	8367	Manoa Marketplace	153.58	153.72
	9032	E. Manoa Rd Bridge	158.65	158.88
	10309	Manoa Park	173.7	173.77
	13136	Poelua St.	208.8	208.8
	15753	Pawale Pl.	259.38	259.38

Based on the results above the Woodlawn Detention reduced the water levels in Manoa by a maximum of approximately 0.2 ft.

Woodlawn Drive Bypass

Since all features that have been tested in the upper Manoa Watershed did not completely reduce the flood waters from leaving the channel on the upstream face of Woodlawn Drive Bridge and traveling through the University of Hawaii, a bypass around the bridge was evaluated. The initial analysis of this option assumed whatever flow that was leaving the right bank at Woodlawn Drive Bridge near Manoa Marketplace would be captured through an inlet on Woodlawn Drive and redirected through a culvert that would run underground and along the driveway for the University's greenhouses and back into Manoa Stream. The intent is to build the system to capture the expected overflow based on whatever features are constructed upstream. This option was modeled by making an initial run to calculate the amount of flow leaving the right bank lateral structure based on the features included upstream. Then another run was made that uses an outlet time series for the lateral structure that which uses the flow hydrograph that was pulled from the first run. This will remove the flow from the system. An identical flow hydrograph was added downstream of the Woodlawn Drive Bridge.

This feature will prevent the flooding through the university except for the university ball fields just north of H1 because these areas are flooded by water leaving the channel on the Manoa-Palolo Canal. However, by redirecting this flow away from the University of Hawaii, the flow in the Manoa Stream will

increase downstream of the Woodlawn Drive Bridge. It's possible that the Kanewai Field Detention may be able to absorb some of this excess flow. Since this feature will be designed to redirect all the flow leaving the channel at the Woodlawn Bridge regardless of the other features designed upstream, the redirected flow will vary per scenario. However, to illustrate the increase in flow on the Manoa Stream, the table below shows Modification 8 which includes the bypass and Modification 7 which is the same as 8 but does not include the bypass.

Table 17: WSEL Comparisons at Select Locations for with and without the Woodlawn Drive Bypass

Reach Name (per HEC-RAS Model)	Cross-Section ID		1% AEP Event (100 year)	
	New 1D/2D Model	Location Description	Modification 7 – without Woodlawn Bypass	Modification 8 – With Woodlawn Bypass
			WSEL (ft)	WSEL (ft)
Manoa Main	948	Kanewai	38.74	39.12
	5461	St. Francis	116.93	117.5
	8367	Manoa Marketplace	154.03	154.05
	9032	E. Manoa Rd Bridge	159.79	159.8
	10309	Manoa Park	174.01	174.01
	13136	Poelua St.	209.78	209.78
	15753	Pawale Pl.	260.59	260.59

The results above show a slight increase in the water level below Manoa Marketplace which is a result of redirecting the flow that would have flowed through the University of Hawaii back into the Manoa Stream. For this particular case the water surface only increases 0.6 ft at St. Francis and about 0.4 ft near Kanewai. For these scenarios, the Kanewai Field Detention Basin was not included in the analysis.

Kanewai Field

Although no modifications were necessarily made to Kanewai Field Detention, several scenarios were made to show the benefits of with and without the detention basin. The effectiveness and the design of the inlet weir will be dependent on the features that will be constructed upstream. The table below shows an example of a comparison between with Kanewai Field Detention (i.e. Modification 13) and without Kanewai Field Detention (i.e. Modification 14).

Table 18: WSEL Comparisons at Select Locations for with and without the Kanewai Field Detention

Reach Name (per HEC-RAS Model)	Cross-Section ID		1% AEP Event (100 year)	
	New 1D/2D Model	Location Description	Modification 13 – with Kanewai Field Detention	Modification 14 – without Kanewai Field Detention
			WSEL (ft)	WSEL (ft)
Palolo Lower	1813		9.94	9.97
	3406		15.84	15.9
Manoa Main	948	Kanewai	40.08	40.4
	5461	St. Francis	118.71	118.71
	8367	Manoa Marketplace	154.58	154.58

Based on the results above, the Kanewai Field Detention reduced the water levels by 0.3 ft at Kanewai, but those reductions were practically eliminated farther downstream on the Manoa-Palolo Canal. However, as seen in the figure below the inundation is impacted some with Kanewai Field Detention in place (blue) versus the detention basin being removed (red). As mentioned above, the effectiveness of the detention basin may be dependent on the upstream structures. Once the upper Manoa Watershed features are designed, the Kanewai Field can be analyzed for its effectiveness to reduce the water levels and/or prevent induced flooding if the Woodlawn Bypass feature is built.

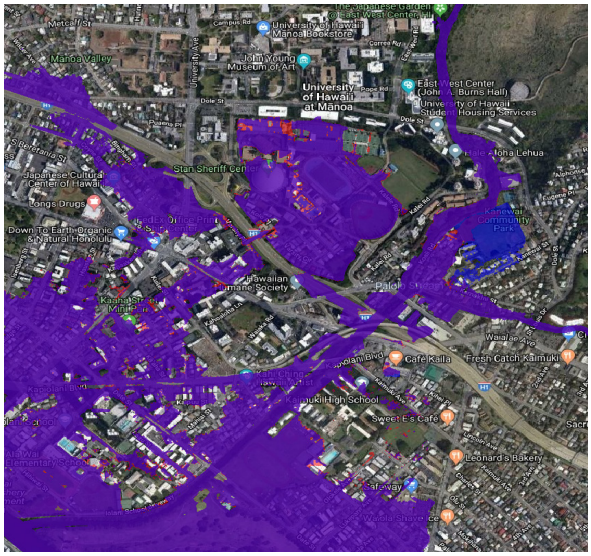

Figure 42: Kanewai Field Detention (blue) versus Without Kanewai Field Detention (red)

After evaluating several modifications and optimizations, it was determined that detention basin(s) located in the upper watershed of Manoa Valley will not achieve the required risk reduction, particularly when considered that the most effective plan (modification 11) which includes Waihi, Waiakeakua, Manoa Park Detention, and the Woodlawn Bypass estimated cost is approximately $70M. Alternatively the least expensive alternative which only incudes the Woodlawn Bypass Culvert, a small floodwall near the Innovation Center, and channel excavation from E. Manoa Rd Bridge to approximately 1,000 ft downstream of Woodlawn Drive Bridge was estimated at a cost of approximately $25M. A comparison of the lateral extent and depth of inundation show that inundation is very similar between Modification 11 and the Woodlawn Bypass Culvert, small floodwall, and excavation only option (considered as a final proposed feature). The figure below shows the difference in the extent between Modification 11 (blue) and the proposed system modification (red). Therefore, the Waihi, Waiakeakua, Woodlawn and Manoa Park detention basins in Manoa Valley has been removed from the flood risk management system. The Woodlawn Bypass Culvert and Kanewai Detention Basin are the only features that will move to the final proposed design.

Figure 43: Inundation Comparison of Modification 11 (blue) and the Proposed System Option (red)

Palolo Modifications

Pukele Modifications

Since the TSP Pukele Detention Basin only reduces the water level by a maximum of approximately 0.1 ft, a modification to the structure was evaluated. The only modification evaluated was to include an in-stream debris catchment similar to the one proposed for Manoa Stream. This option was evaluated in modifications 2, 3, 6, 7, and 8 using the same methodology as the Manoa In-Stream Debris Catchment. However, after making these modifications, during a meeting in August of 2018 in Honolulu, city and county personnel informed the team that the Pukele, Waiomao, and Makiki have not had a history of debris issues. Only Manoa has a history of debris issues with the 2004 event being an example of debris issues. Due to several restrictions in the watershed, a new location or modified dimensions of the Pukele Detention Basin was not feasible. Since the Pukele Detention was not found to be effective, the feature was removed for subsequent (i.e. Modifications 9-16) model runs.

Waiomao Modifications

Since the TSP Waiomao Detention Basin only reduces the water level by a maximum of approximately 0.2 ft, modifications to the structure were evaluated. Two modifications were considered on top of the TSP design. Both plans assumed an automated gate. An option to include an automated gate at the TSP site was first considered and then an option was considered for the detention basin to be moved upstream and for it to also include an automated gate. A separate HEC-RAS model was created just for the structure and included just enough cross-sections downstream to compute an outflow.

For the first modification, the Waiomao Detention Basin was slightly modified from the TSP design. The design assumes the same embankment elevation of 402 ft, a concrete-lined emergency spillway 75 ft wide but the elevation was raised to 400.0 ft, and the box culvert was replaced with a 12 ft wide by 7 ft high gate with an invert set to elevation 370.5 ft. The operation was set to release a max of 1,750 cfs which compares to the approximately 2,350 cfs release from the TSP and the approximately 2,480 cfs without project.

The second modification moved the detention basin further upstream. The design assumes an embankment elevation of 580 ft, an emergency spillway 50 ft wide with an elevation of 578 ft, and a 14 ft wide by 8 ft high gate with an invert set to elevation 529.4 ft. The operation was set to release a max of 1,120 cfs which compares to the approximately 1,750 cfs for the first modification, 2,350 cfs release from the TSP and the approximately 2,480 cfs without a project.

The table below shows a comparison of water levels for the different modifications of the Waiomao Detention Basin. Modification 5 includes the TSP operation, Modification 2 includes the automatic gates at the TSP location, and Modification 3 includes the upper basin location with automatic gates.

Table 19: WSEL Comparisons at Select Locations for Makiki Detention Basin Modifications

Reach Name (per HEC-RAS Model)	Cross-Section ID		1% AEP Event (100 year)			
	New 1D/2D Model	Location Description	Modification 2 – TSP w/ Gate & Pukele Debris only	Modification 3 – Upper Detention w/ Gate & Pukele Debris only	Modification 4 – TSP Waiomao & TSP Pukele	Without Project
			WSEL (ft)	WSEL (ft)	WSEL (ft)	WSEL (ft)
Waiomao Tributary	1724		268.36	267.19	269.23	269.42
Palolo Main	11649	Palolo Hongwanji	138.05	137.92	138.08	138.38
	14619	Palolo District Park	188.01	187.59	188.21	188.63

Based on the results, the TSP design with a gate does provide almost 1.0 ft reduction on Waiomao when compared to the without project features but this reduction is quickly diminished as you progress downstream due to the attenuation of the downstream bridge restrictions. The upper basin detention with a gate reduces the water levels by a little over 2.2 ft on Waiomao but once again this difference is diminished as you progress downstream. However, as pointed out on the automatic gates for Waihi and Waiakeakua due to the complex nature of the gates, the additional expense, the maintenance, and the potential for the system not working when needed, the automated gates were removed from consideration, especially given limited gains from using these gates. In addition, Since the Waiomao TSP Detention was not very effective, the feature was removed for subsequent (i.e. Modifications 9-16) model runs.

The features developed in the feasibility phase and numerous modifications evaluated during the post-feasibility phase do not significantly reduce localized flooding or WSEL at the confluence with Manoa Stream. Therefore, the detention basins in Palolo Valley will be removed from the risk management system when considered collectively with the limited, relatively shallow inundation, an estimated $37M of construction costs, land acquisition requirements, and the unwanted impacts to the environment and community.

Proposed Final Features

Overview

Due to the results of this analysis, the structures on Makiki and Palolo portions of the watershed were determined to be ineffective due to the limited storage capacity that could be reasonably excavated and were removed from the study. As previously shown, significant attenuation behind downstream bridges on the Manoa Portion of the watershed negated most of the effects of the reduced peak flow and the limited benefits of most of the structures were not considered economically justifiable. As a result, the

Waihi, Waiakeakua, Woodlawn Detention, and Manoa Park structures were also removed from the study. The features that will be carried forward in the Proposed Final design include the following six structural elements:

- Two stream diversions
  - Makiki Stream Diversion
  - Woodlawn Drive Bridge Diversion
- Three multi-purpose detention basins
  - Ala Wai Golf Course Detention
  - Hausten Ditch Detention
  - Kanewai Field Detention
- Floodwalls along Ala Wai Canal (including pump stations for interior drainage)

The hydrology for the proposed final features model scenario was updated to use a 12-hour duration 100-year frequency flow developed using HEC-WAT. Plots and tables of the hydrographs used for the 100-year frequency event can be found in the appendix of this report. Details of the flows used in the post-feasibility study can be found in the Post-Feasibility Hydrology Report. In addition, the without project condition model scenario was also updated to run the HEC-WAT derived frequency flows in order to provide a comparison of the results. Finally, the post-feasibility TSP design was run using the HEC-WAT flows so that the economic analysis could be conducted on this scenario and compared to the proposed final feature scenario. As stated in the post-feasibility section of this report, all other scenarios used a basin average 100-year 24-hour duration Atlas 14 frequency flow since the HEC-WAT derived flows were not available at the time the other scenarios were modeled.

Makiki Watershed

Findings from the hydrologic and hydraulic analysis in Makiki Valley necessitated a conceptual shift from maximizing flood water detention to enhanced conveyance to manage flood risk.

The use of extended floodwalls along Makiki channel upstream of Kapiolani Blvd Bridge was also explored. Modeling results indicate the floodwalls would need to extend a significant distance to reach a topographic elevation high enough to overcome the WSEL and commensurate hydraulic head at the confluence with the Ala Wai Canal. Additionally, the floodwalls would need to be constructed for long distances on the top of existing historic walls on the Makiki Stream or in narrow channels through densely urbanized businesses and residences. The existing walls often butt directly against the tops of this narrow, vertical-walled storm water channel, further complicating construction and significantly increasing cost.

A diversion culvert was examined rather than pursue extending floodwalls due to logistical and cost challenges. A culvert with approximate dimensions of 1,500 feet long by 20 feet wide by 10 feet deep to supplement the conveyance of floodwater was considered. After a series of models, including supplemental small pumps, it was determined that a culvert beginning at the Makiki channel running parallel to the canal to a discharge point just upstream of Ala Moana Blvd Bridge would significantly reduce backwater conditions and prevent overtopping of the channel in the McCully and Moiliili area. This design concept requires further evaluation for performance optimization, environmental impacts, and cost effectiveness as part of the final design.

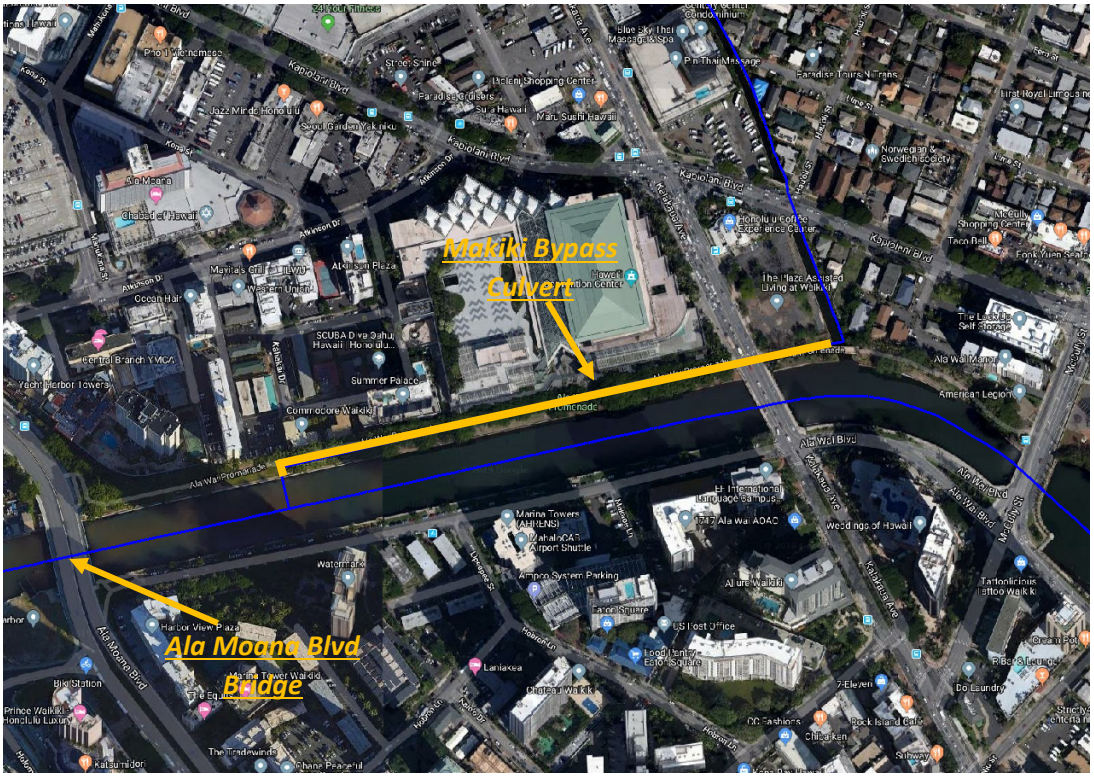

Figure 44: Conceptual footprint of Makiki Diversion

Manoa Watershed

The proposed path forward for the system model is to perform excavation from E. Manoa Rd Bridge to approximately 1,000 ft downstream of Woodlawn Dr Bridge, constructing a small levee on the left bank between E. Manoa Rd Bridge and Woodlawn Drive Bridge, and constructing a box culvert 15 ft wide by 10 ft high redirects water around Woodlawn Dr Bridge. The figure below shows the approximate alignment of the box culvert.

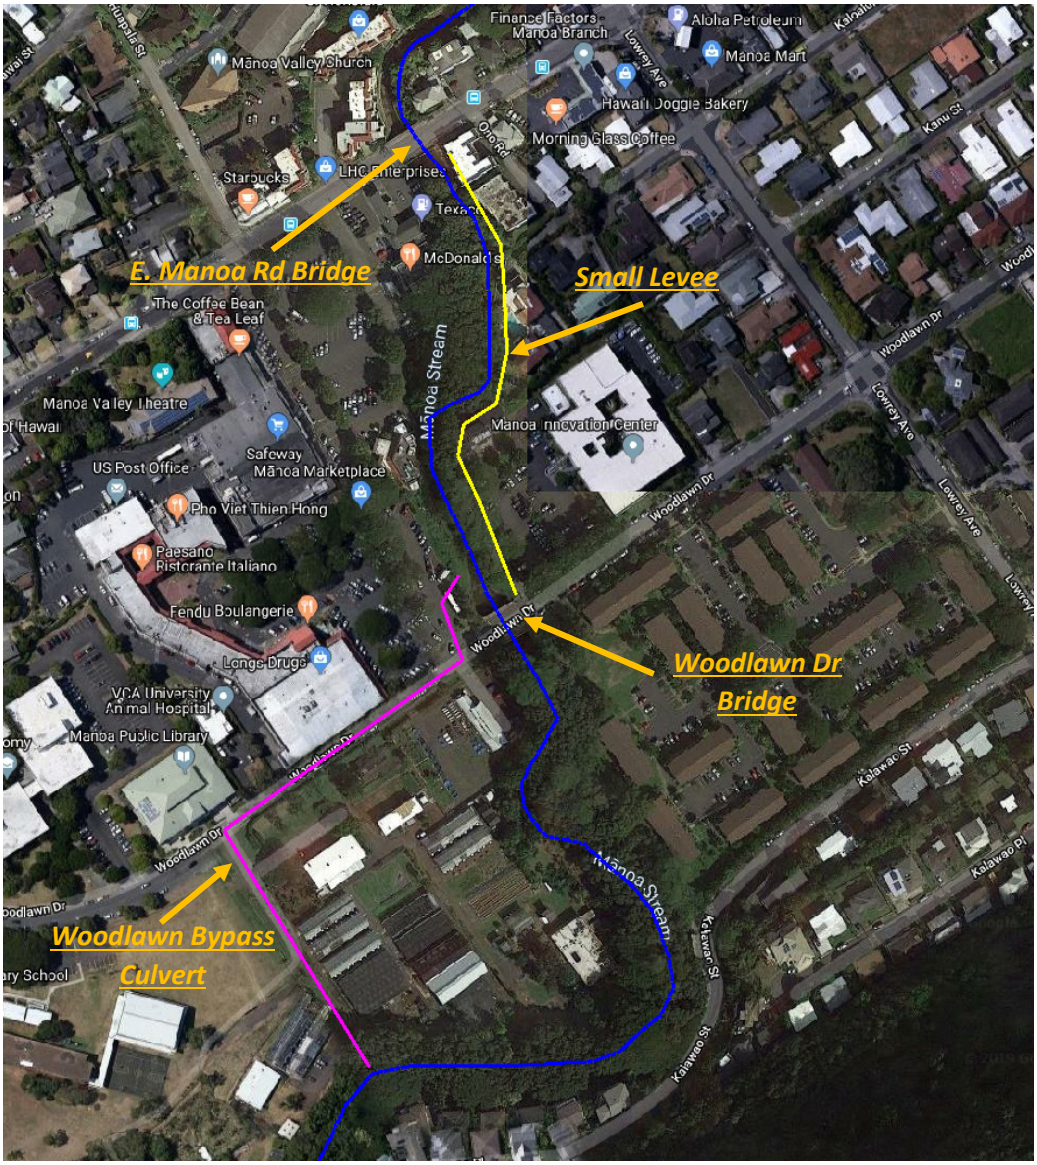

Figure 45: Conceptual footprint of Woodlawn Bypass Culvert

Palolo Watershed

The features developed in the feasibility phase and numerous modifications evaluated during the post-feasibility phase do not significantly reduce localized flooding or WSEL at its confluence with Manoa Stream. Therefore, no features were included in the Palolo Watershed.

Lower Watershed

Golf Course

Results of the modeling indicate the planned berm alignment at the northern and eastern perimeter of the golf course prevent overland flow from uplands north from reaching the Ala Wai Canal and consequently induced flooding. Hydraulic modeling shows the sheet flow was pushed eastward, flanking the berm and increased inundation along a major north/south thoroughfare, Kapahulu Avenue.

A new design was developed which includes 2 berms running north to south across the golf course, in conjunction with a pump placed on the Ala Wai Canal just upstream of its confluence with the Manoa-Palolo Canal. The figure below shows the conceptual footprint of the golf course berms. In addition to the berms, a sedimentation basin would be placed in the terrain on the west side of the golf course.

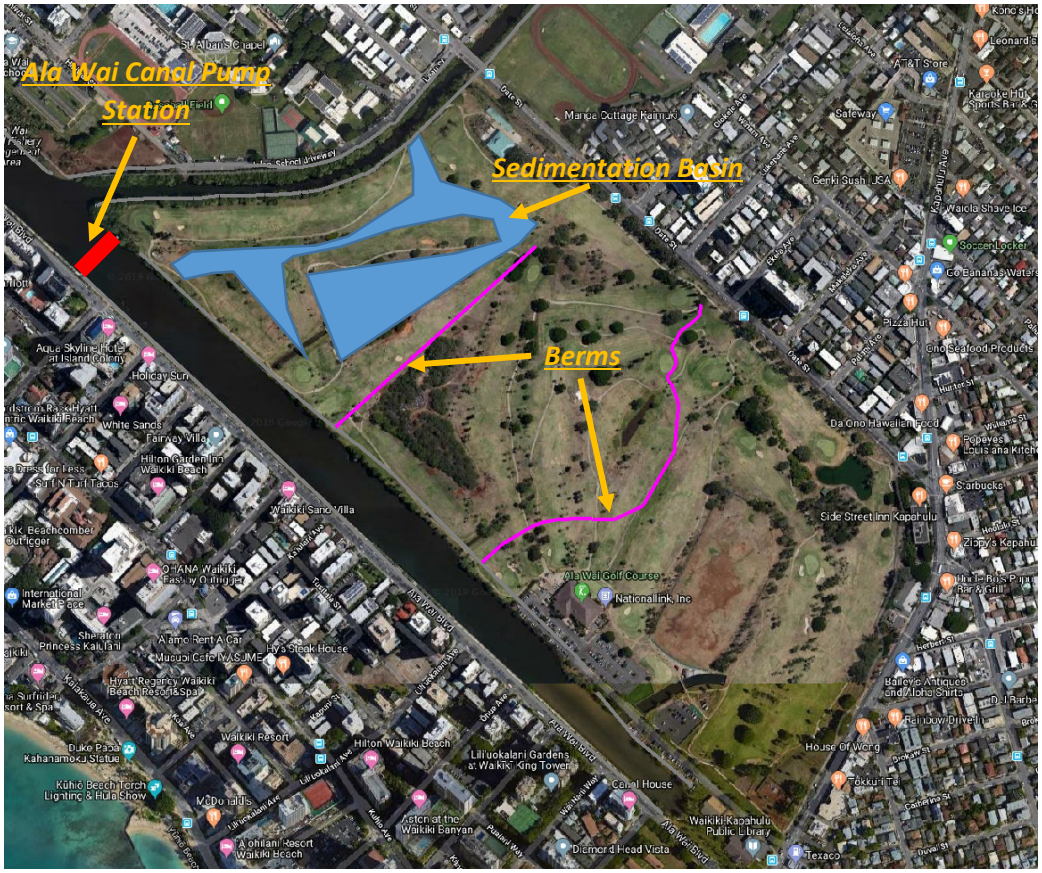

Figure 46: Conceptual footprint of Golf Course Berms

Floodwalls and Pump

For the final proposed design, the floodwalls on the Ala Wai Canal and the floodwall on the right bank of the Manoa-Palolo Canal from the confluence with the Ala Wai Canal up to Date street remain unchanged from the post-feasibility analysis with the exception of removing the segment of the floodwall on the upper portion of the canal. The segment that was removed was the on the left bank of the upper Ala Wai Canal across from the Ala Wai Golf Course. The upstream section of the left bank floodwall now begins at the proposed location of the pump station instead of the upstream end of the canal near the library. The figure below shows the proposed alignment of the floodwalls. If the Makiki Diversion is accepted, the floodwall will block the current Makiki outlet and extend down to the new Makiki Outlet.

The original study considered two pump stations but after several iterations by the New Orleans district, The recommended plan consolidates two pump stations into a single 4,000 cfs pump and relocates the pump on the Ala Wai canal to just upstream of the confluence with the Manoa-Palolo Canal.

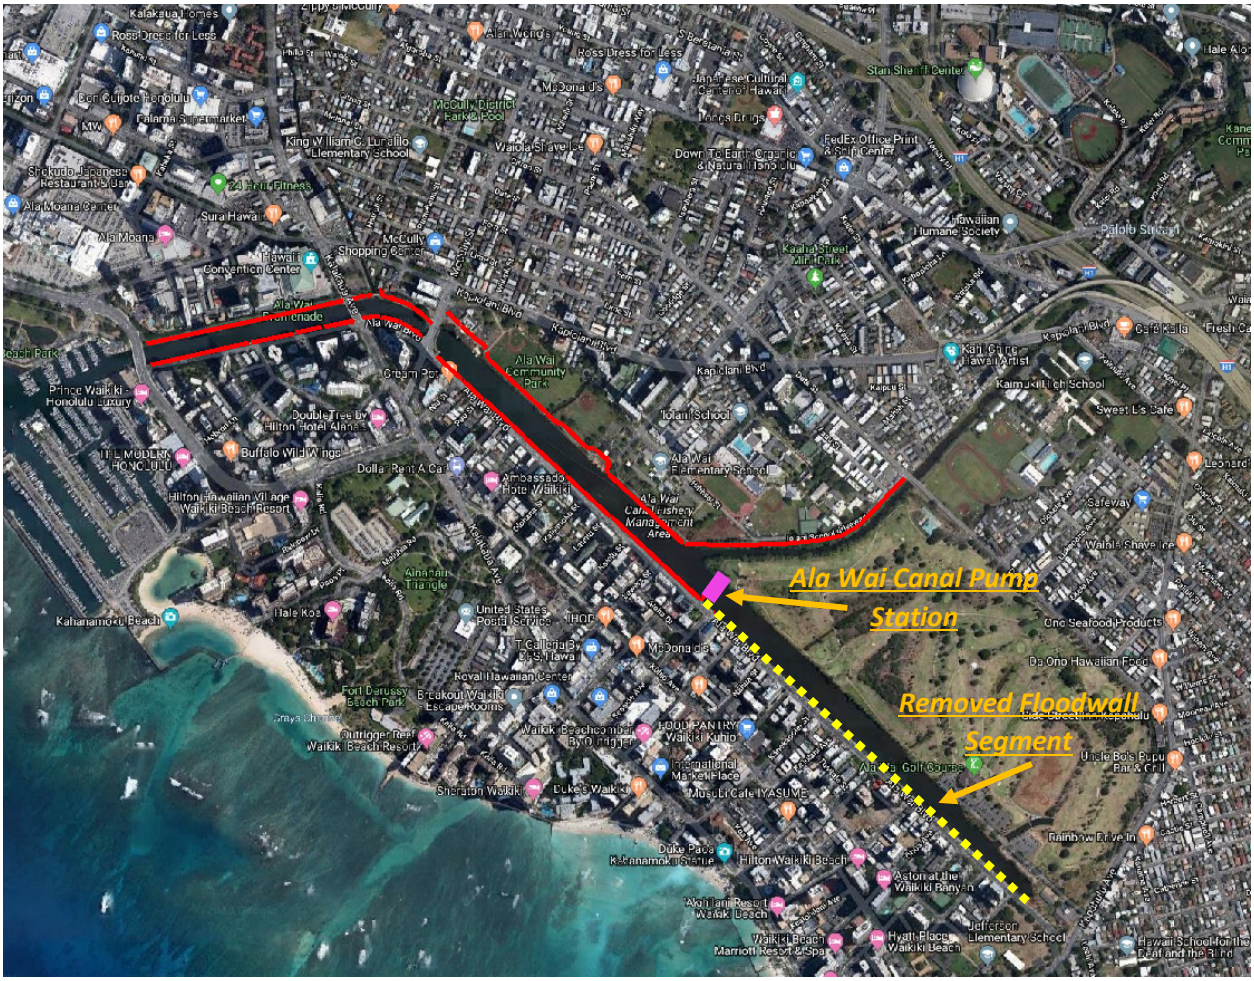

Figure 47: Proposed Final Floodwall Alignment

Kanewai Field

Kanewai Field currently remains in the future proposed features as designed in the post-feasibility TSP analysis but will need to be evaluated based on its effectiveness once the upper Manoa Valley features are fully designed and accepted.

Results

The table below shows the results of the proposed system model versus the without project conditions. The last column shows the difference between the proposed final features plan and the without project plan. A positive value indicates that the proposed final feature plan has a higher WSEL than the without project conditions. The Ala Wai Canal and the areas of the other streams near the confluence with the Ala Wai Canal are higher in the proposed final feature plan compared to the without project plan because the floodwalls are containing the floodwaters that would have otherwise been in the overbanks. A negative indicates a reduction in WSEL with the proposed final features in place as compared to the without project conditions and a zero value indicates no change between the with and

without project features. The comparison uses the 12 hr duration event (100 year) that was from the HEC-WAT derived frequency flows.

The proposed final features reduce the flooding through the University of Hawaii and reduce the severity of flooding in the lower watershed around Waikiki, Iolani, McCully, and the Moiliili areas.

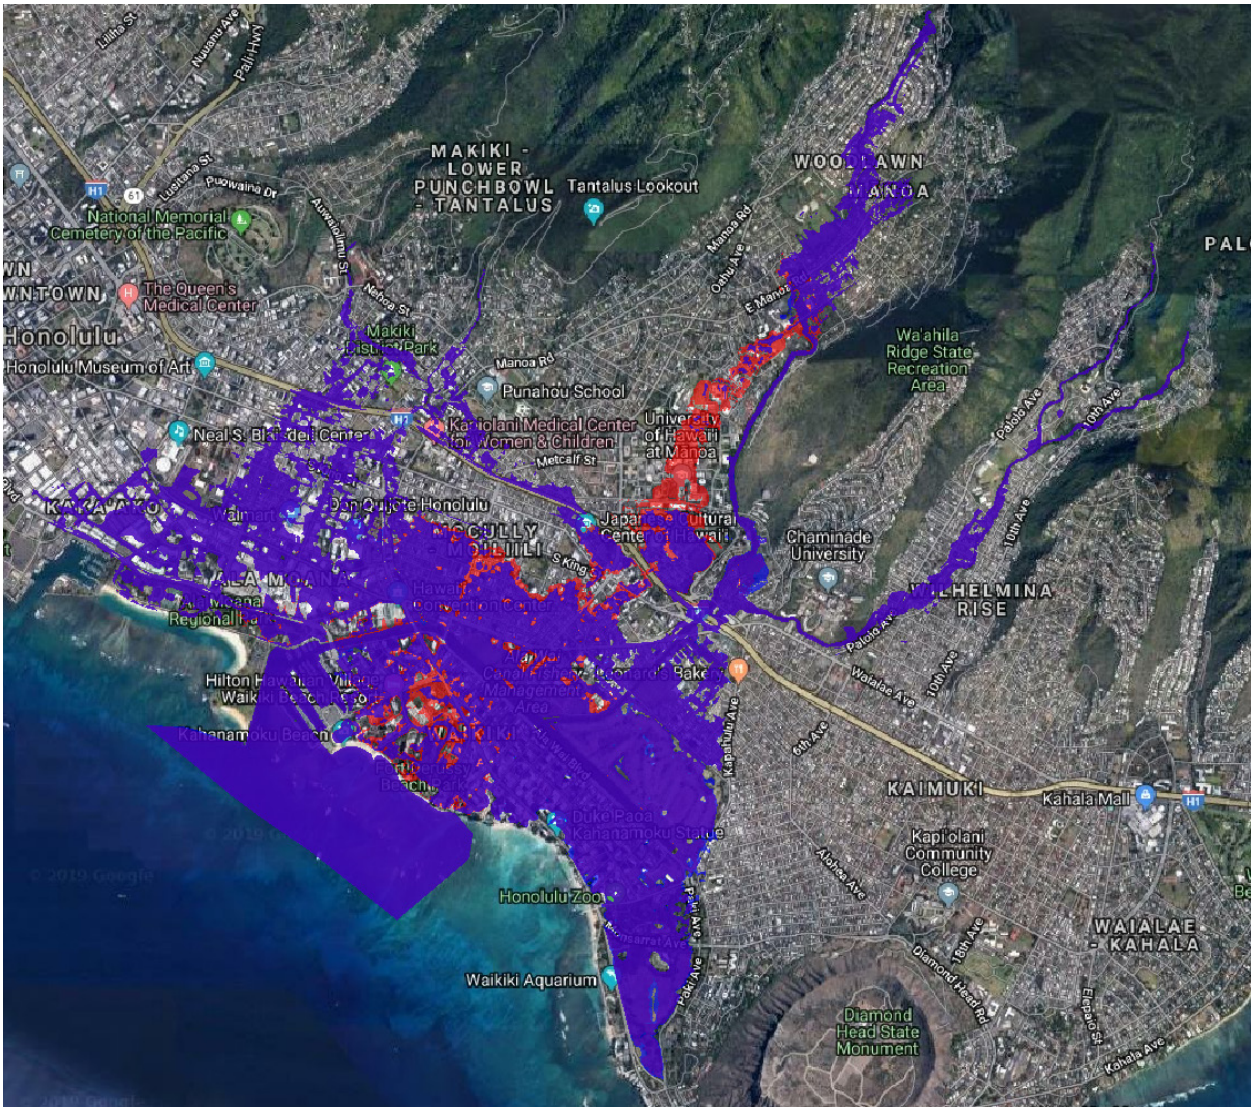

Figure 48: Inundation Comparison of without projects (red) and with proposed final features (blue/purple)

Summary and Conclusions

In summary, while the project objective remains the same as the plan advanced through the planning, engineering, and design phases, the approach evolved based on better data and better hydraulic modeling. Results of the HEC-RAS 1D/2D unsteady state modeling and accompanying engineering analysis support a shift from flow detention in the upper watersheds to improved conveyance for greater control and risk management throughout the downstream system.

Key findings summarized below:

Upper Watershed - Makiki Valley, Manoa, and Palolo Valleys

- Extent of inundation was not as severe as estimated with HEC-RAS 1D modeling in Makiki and Palolo Valleys, therefore the requirements and benefits of detention basins in the upper watersheds were reduced
- Significant flooding was observed throughout Manoa Valley in HEC-RAS 1D steady and HEC-RAS 1D/2D unsteady state modeling, particularly in the Manoa Marketplace stream reach
- Overtopping at the Woodlawn Drive Bridge occurs without the presence of the bridge due to stream channel constraints, which are amplified by the presence of the bridge substructure and historic debris blockages
- HEC-RAS 1D/2D modeling showed storage capacity of detention basins could not be cost effectively expanded in the upper valleys to reduce flows enough to prevent overtopping at numerous constrictions along the routing
- Recommend replacing the Makiki detention basin planned in upper Makiki Valley with a culvert diversion at the confluence with the Ala Wai canal pending further engineering investigation
- Recommend removing Waihi, Waiakeakua, and Woodlawn Ditch detention basins and improve conveyance at the Manoa Marketplace stream reach with stream deepening, floodwalls, and a culvert bypass at the Woodlawn Drive Bridge to keep storm flow within the stream channel and prevent downstream flooding of neighborhoods and University of Hawaii campus
- Recommend replacing Waiomao and Pukele detention basins with floodwalls extended northward from the Ala Wai canal to the Date Street Bridge to maintain storm flow within the stream channel and prevent flooding of the neighborhood, ‘Iolani and Ala Wai Elementary schools

Lower Watershed – Ala Wai Canal, Golf Course, Hausten Ditch

- Widespread flooding will occur across the base of the Ala Wai watershed, north and south of the Ala Wai canal in a 1% annual exceedance probability event
- Consolidation of two large capacity pump stations into a single 4,000 cubic feet per second pump station at the confluence of the Manoa-Palolo channel and the Ala Wai canal
- Pump station(s) placement at the eastern end of the Ala Wai canal enhances efficacy of existing interior storm water drainage in the Kapahulu and Diamond Head neighborhoods

The figure below graphically summarizes the recommended modifications to the flood risk management features planned during the feasibility phase.

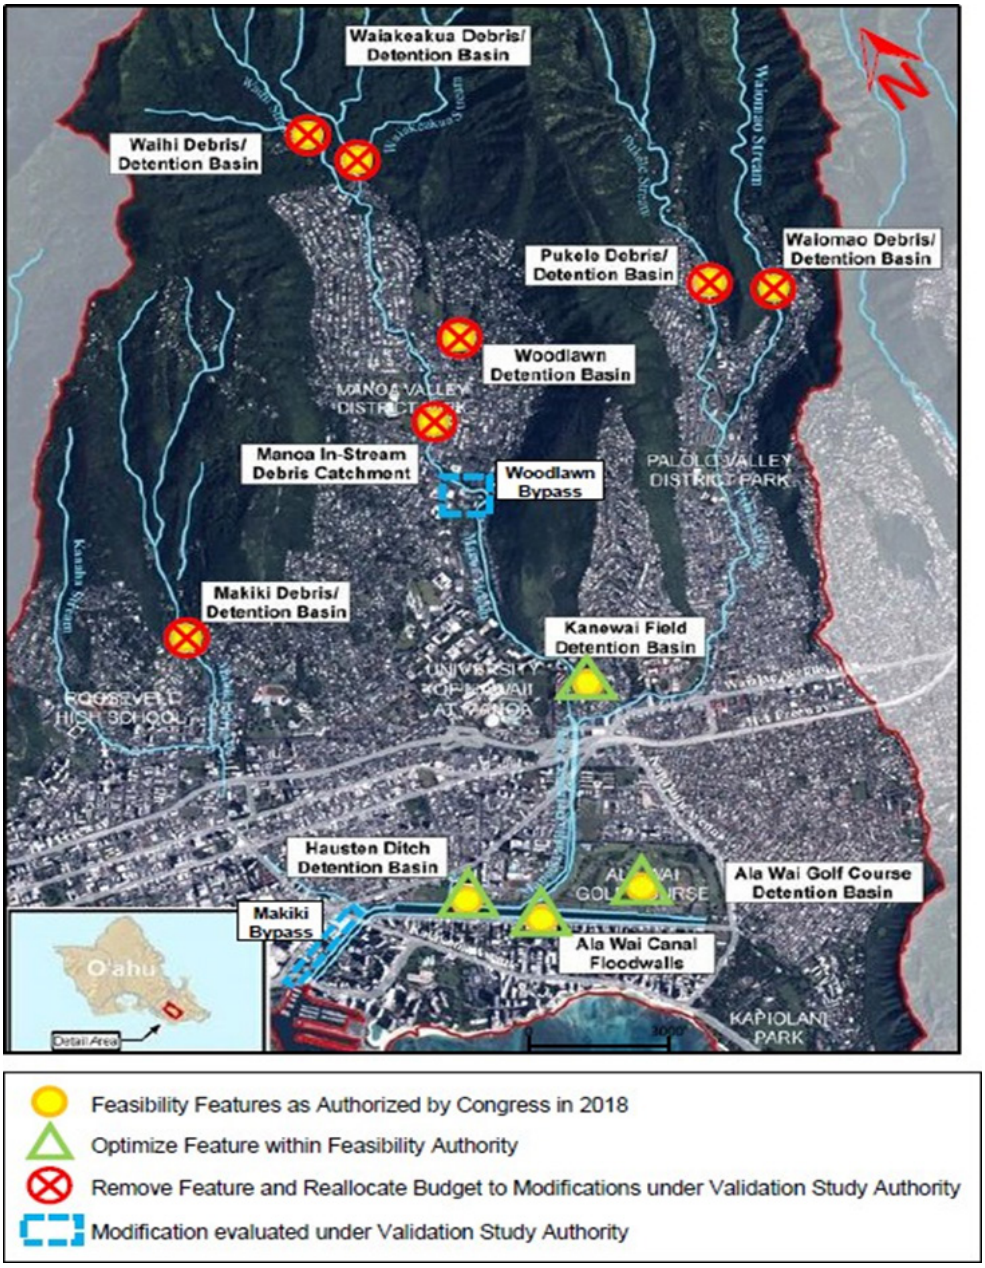

Figure 49: Recommended Modifications to the authorized FFEIS Project

Future Considerations

Currently, all scenarios in this report are based on a basin average Atlas 14 rainfall (i.e. the same precipitation was used for all sub basins), since this was the same methodology used for the Atlas 14 routings in the feasibility studies. However, for the hydrology effort, the frequency routings were completed through a variety of methods. These included an Atlas 14 method for both averaged and confidence interval precipitation, spatially varied Atlas 14 for both averaged and confidence interval precipitation, and HEC-WAT routings for a 12- and 24-hour events. Confidence interval data is available for HEC-WAT routings but was not post processed in HEC-SSP or routed though HEC-WAT. Only the 12-

hour duration frequency events were post-processed in HEC-SSP. For the final design efforts, it is recommended that the 12-hour HEC-WAT routing be considered as the most accurate and appropriate.

Additionally, the probable maximum precipitation (PMP) should be estimated and routed through the HEC-HMS model to produce the probable maximum flood (PMF). Currently, the only basin remaining in the recommended plan is the Kanewai Field Detention which may require a PMF scenario for design.

Finally, as described above, the availability of data to calibrate the HEC-RAS model was highly limited due to the number of gages available during the calibration events and the frequency in which the data was recorded. However, additional gages have been added in the watershed by USGS (including one on Makiki) and the data is currently collected at 5-minute increments. As a result, additional calibration events would be beneficial to use to better calibrate the model. The use of more calibration events was outside the scope of this effort.

Hydraulic Information for Economic Analysis

As part of this effort, an economic analysis was performed using the Hydrologic Engineering Center Flood Damage Reduction Analysis (HEC-FDA) software. This analysis requires multiple inputs from the hydraulic analysis which includes cross-section range and index location for each damage reach, bank elevations, channel inverts, water surface profiles for the 8 exceedance probability flood events, stage-discharge standard deviation, and input on re-delineation of damage reaches. Below is a list of the plans that were analyzed as part of the economic analysis.

- Future without-project condition– indexed to future without project conditions of 2075 and based on an intermediate scenario pertaining to sea level rise. Uses HEC-WAT derived frequency flows.
- Future with- post-feasibility TSP project condition – used for analysis of the post feasibility tentatively selected plan features indexed to year 2075. Uses HEC-WAT derived frequency flows.
- Future with-proposed final features project condition – used for analysis of the new proposed final features indexed to the year 2075. Uses HEC-WAT derived frequency flows.

Damage Reaches

The economic analysis was based on the same methodology as the original feasibility study but due to updates to the HEC-RAS 1D/2D model, some edits to the damage reaches have been made. Damage reaches in HEC-FDA are geographical areas that are used to aggregate structure data and other damage information within a floodplain. The changes to the feasibility study damage reaches include expanding some damage reaches to encompass the new inundation extents. The new HEC-RAS 1D/2D provides more detailed modeling in the overbanks areas and as a result, there are some differences in the overbank inundation compared to the feasibility study. Additional edits to the damage reaches included merging some of the reaches since the stream reaches for the University Split reach and the Kanaha Split reach no longer exist in the updated HEC-RAS model. These reaches were replaced with 2D flow areas and so the stream reach and cross-sections do not exist. The University Split reach that modeled the flows through the University of Hawaii was merged with adjacent reaches on the Manoa Stream. The UNI1 damage reach was merged with MAN1 damage reach and the UNI2 was merged with MAN2

damage reach. For the Kanaha Split reach that was used to model overbank flows to the south of Kanaha Stream, the damage reach KAO1 from the Kanaha Split stream reach was merged with the KAH1 damage reach. Below are figures showing the damage reaches from the feasibility study and the new post-feasibility damage reaches. The figure also shows the without project inundation for the 100-year flood event. The basis for the delineation of the original damage reaches can be found in Appendix B of the feasibility study, as well as other pertinent data and assumptions made for the HEC-FDA model.

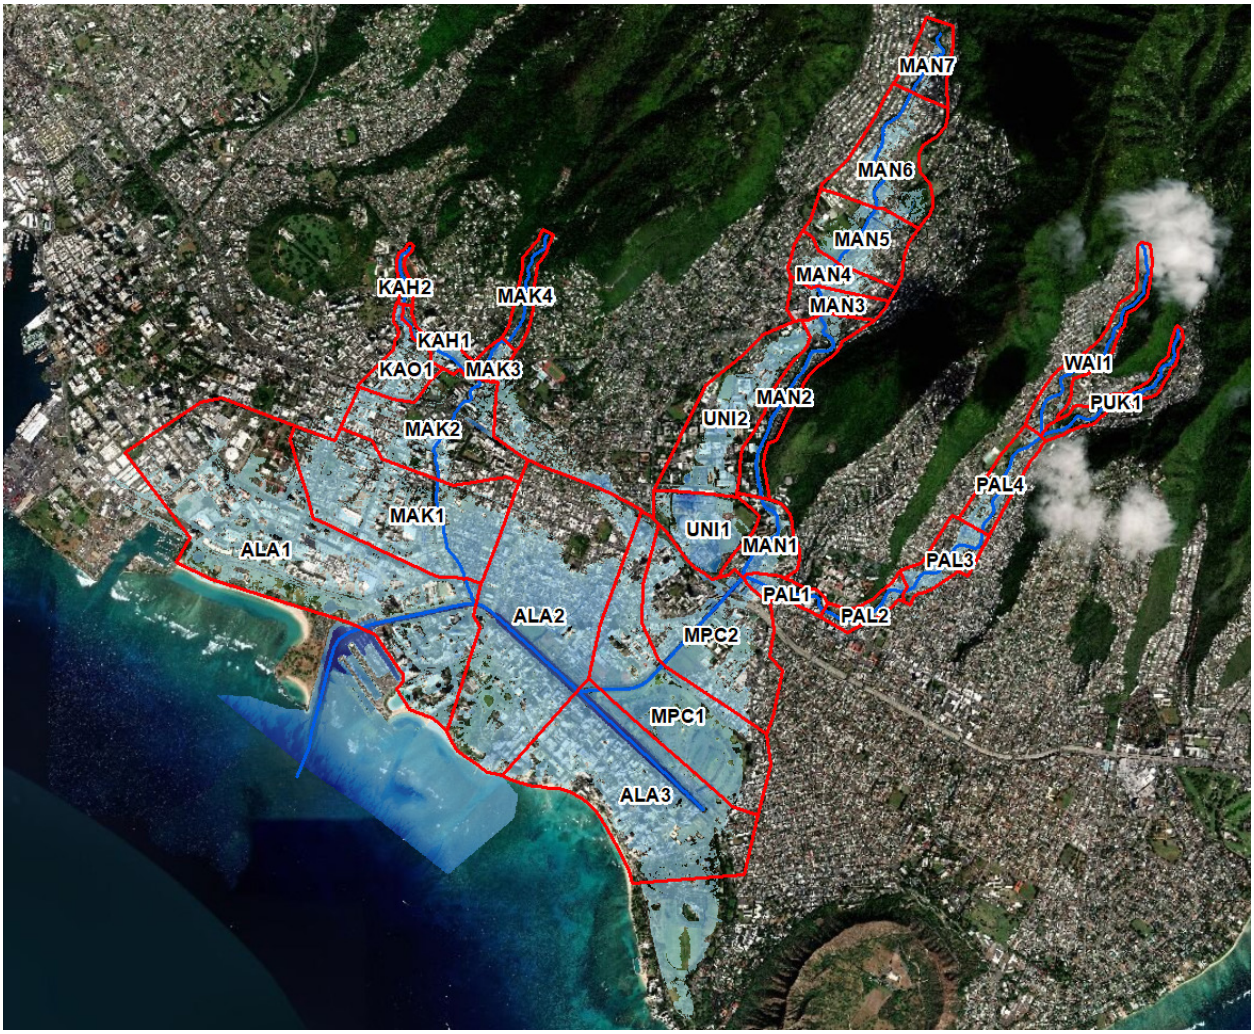

Figure 50: Damage Reach Layout from Feasibility Study

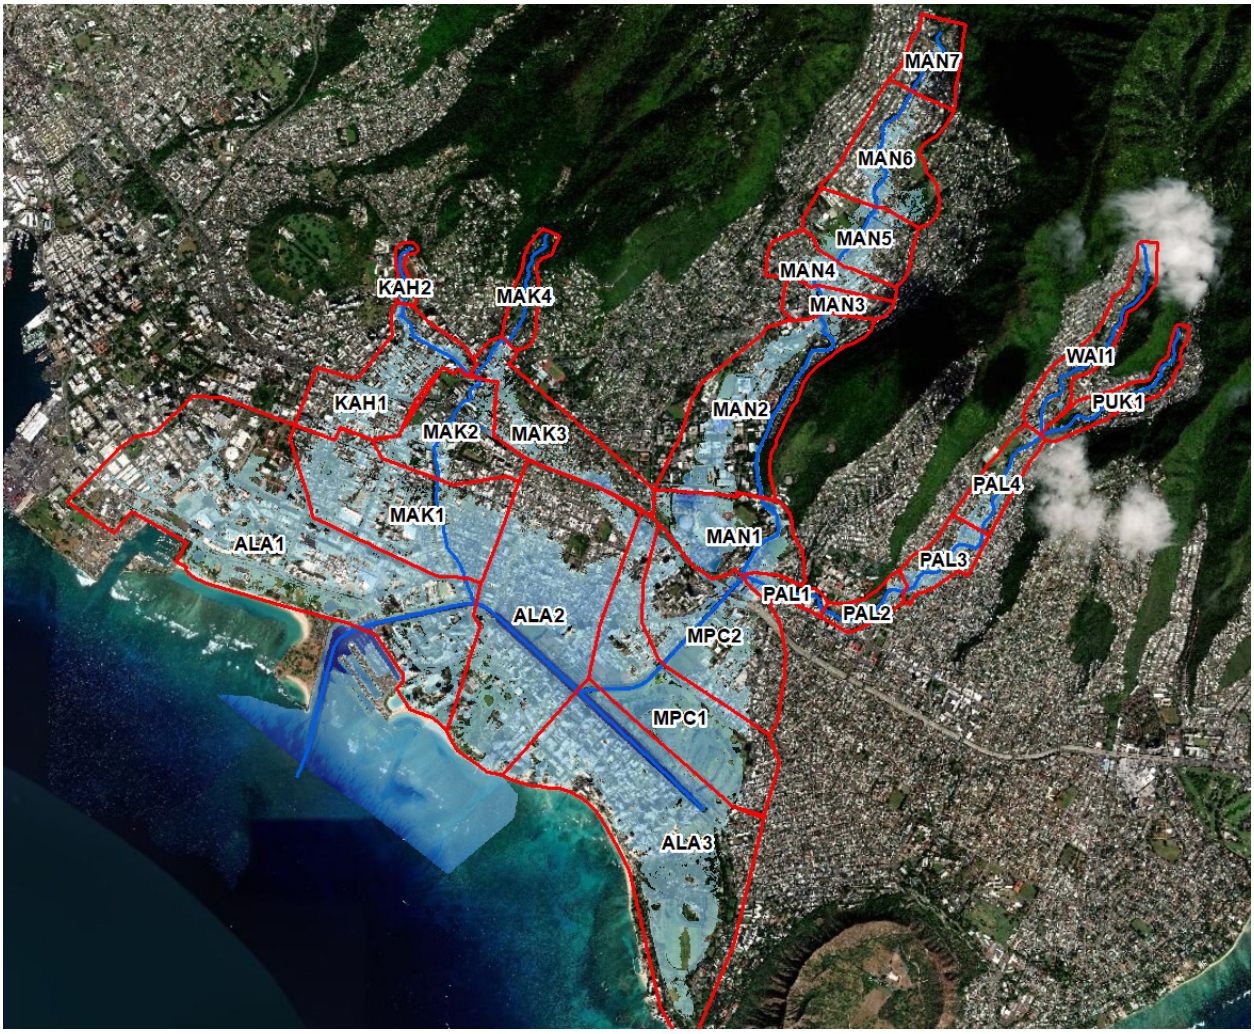

Figure 51: Updated Damage Reach Layout for Post-Feasibility Study

Damage reaches in HEC-FDA also require additional information such as the upstream and downstream river stations from HEC-RAS, an index location, channel invert of index location, and bank elevations at the index location. The index location is a location between the upstream and downstream station for the reach and is selected to specify the stage-discharge, the discharge probability, and stage damage functions with uncertainty for the damage reach. The index location was selected based on location that would represent the reach and would provide reliable data. The index location for some damage reaches were changed for some plans due to the structures and the reliability of the data. For example, the ALA3 index location was changed for the post-feasibility proposed final features plan due to the pump station that was added to that reach. The index location was moved closer to the confluence of the Manoa-Palolo canal and downstream of the pump station since this area would be more representative of the water surface in the canal instead of upstream of the pump station which will be lowered by the pump station. Other examples included locations that may have been impacted by project features and which may have caused a loop effect on the rating curves for the area. There were a few areas such as the Ala Wai upper canal that saw a continuous increase in WSEL over the 8

frequencies, but the flow may have reduced for the lower frequency events due to an increase in backwater effects. Below are tables of the downstream stations, upstream stations, index locations, channel invert, and bank elevations used for the different plans.

Table 21: HEC-FDA Damage Reach Information for Future Without Project Conditions

Damage Reach	Stream	Downstream Cross Section	Upstream Cross Section	Index	Channel Invert at Index Location	Bank	Right Bank Elevation (ft)	Left Bank Elevation (ft)

Water Surface Profiles

In addition to the parameters listed in the previous section, HEC-FDA also requires water surface profiles from the HEC-RAS model. The water surface profiles can be extracted from the HEC-FDA table in the summary output tables in HEC-RAS. These tables can also be exported from HEC-RAS as .wsp file that can be imported directly into HEC-FDA. The water surface profile information includes the max WSEL, max flow, and min channel elevation at a cross-section for each of the probability exceedance events. To

produce this information, all 8 frequency events were run for each project configuration (i.e. without project, post-feasibility TSP features, and proposed final features). The table below shows the stage-discharge relationship for the index location in each of the damage reaches for the different frequency events.

Table 24: Water Surface Profiles from HEC-RAS for the Three Project Configurations

			Without Project		Post-Feasibility TSP		Proposed Final Features	
Reach	**Probability**	**Return Period**	**Flow (cfs)**	**WSEL (ft)**	**Flow (cfs)**	**WSEL (ft)**	**Flow (cfs)**	**WSEL (ft)**

Stage-Discharge Function with Uncertainty

In HEC-FDA, the stage-discharge information is imported from the water surface profile information from HEC-RAS model that is detailed in the section above. For this study, a normal distribution was used to represent uncertainty for this data and that option required a standard deviation for each damage reach. The standard deviation was determined by running a sensitivity on the manning's "n" values in the HEC-RAS model. To test the sensitivity, model runs were made with the "n" values varying on average by +/- 20% for the without project plan, post-feasibility TSP plan, and the proposed final features plan. The range of roughness values was estimated at each location to determine a realistic high and low value for the area. The difference in stage between the high estimate and low estimate was calculated for each cross-section. For each damage reach, an average stage difference was determined for the cross-sections contained within the damage reach. To estimate the standard deviation relative to the mean stage for the 95% confidence interval for a normal distribution, the

difference in stage between the high and low was divided by 4 (+/- 2 standard deviations). The calculated standard deviations for each damage reach for the different project configurations can be found in the table below.

Table 25: Stage-Discharge Standard Deviations

Reach	Stream	Without Project	Post-Feasibility TSP	Proposed Final Features	Adopted Standard Deviation*

*MINIMUM STANDARD DEVIATION AS SPECIFIED IN EM 1110-2-1619

Table 26: Minimum Standard Deviations of Error in Stage (Table 5-2 from EM 1110-2-1619)

Manning's n Value Reliability[1]	Standard Deviation (in feet)	
	Cross Section Based on Field Survey or Aerial Spot Elevation	Cross-section based on Topographic Map with 2-5' Contours
Good	0.3	0.6
Fair	0.7	0.9
Poor	1.3	1.5

[1]Where good reliability of Manning's *n* value equations relate to excellent to very good model adjustment/validation to a stream gauge, a set of high-water marks in the project effective size range, and other data. Fair reliability relates to fair to good model adjustment/validation for which some, but limited, high-water mark data are available. Poor reliability equates to poor model adjustment/validation or essentially no data for model adjustment/validation

The Engineer Manual (EM) 1110-2-1619, *Risk Based Analysis for Flood Damage Reduction Study,* provides guidance on determining standard deviations. Table 5-2 from EM 1110-2-1619 describes the minimum standard deviation of error in stage that can be used for a flood damage reduction study. The table is reproduced above. As stated in the Terrain section of this report, the LiDAR data has an accuracy of 45 cm (1.5 ft) horizontal, 37 cm (1.2 ft) vertical and was processed with 1 ft horizontal point spacing and survey data was provided for some channel data. The manning's "n" values were considered "Fair" due to the limited calibration data and coupled with the use of LiDAR and survey data, the minimum standard deviation of error in stage was determined to be 0.7 ft. Since the calculated standard deviations for every reach was lower than the minimum standard from EM 1110-2-1619, a 0.7 ft standard deviation was adopted for all reaches across the 3 project configurations.

December 6-8, 2021 Rainfall Event on Ala Wai Watershed

Summary

An unusual December storm was experienced throughout Hawaii on 6-8 Dec 2021. The following is an excerpt from National Weather Service report on the event:

> *A strong kona low developed northwest of the main Hawaiian Islands and produced heavy rainfall and strong winds over many areas of the state. The main rain band hit the Big Island first on Sunday, December 5, then shifted slowly westward across the island chain over the next two days. Rainfall totals were greatest over the southeastern flank of the Big Island, the south- and west-facing slopes of Haleakala, and most of Oahu,…*
>
> (https://www.weather.gov/hfo/konaLowDec2021)

At request of local sponsor for use in communications with local media, the H&H PDT examined gauge records, published frequency information, and prior study information to assign an estimate of the return frequency for this event. It should be noted that this analysis exclusively focused on the Ala Wai watershed (Manoa, Palolo and Makiki subbasins) and may not be representative of other portions of Oahu or Hawaii. Based on both a precipitation frequency analysis and flow frequency analysis of gages within the basin, the storm event can be characterized as approximately a 0.2 Annual Exceedance Probability (AEP) (commonly referred to as a "5-year") event. Analysis of both precipitation gauges and discharge gauges is performed in order to gain an overall understanding of the storm event and the watershed response, given that any individual result can be highly localized and not reflective of the overall event.

Precipitation Gauge Analysis

Data from five rain gages were used in the precipitation frequency analysis as shown in Table 1. The gauge locations are shown in Figure 1. The reported total precipitation at the Waihi gauge for the event (0.29 inches) was a significant outlier compared to surrounding totals, therefore it is excluded from further study. No precipitation gauges were readily available in the Palolo watershed. 24-hour precipitation maximums ranged from approximately 7.8 inches (Honolulu 0.5 SSE) to 8.9 inches (Lyon Arboretum).

Based upon published precipitation frequency estimates by the National Weather Service (NOAA Atlas 14), these precipitation totals would fall generally between a 0.04 and 0.2 annual exceedance probability ("5-25" year) event, with the precipitation recorded at the Honolulu 2.0 SW gauge in the lower portion of the Makiki watershed within the 90% confidence band for a 0.04 AEP. Precipitation totals trended toward an 0.20 AEP on the eastern edge of the Manoa watershed. Excerpts from the Atlas 14 data server are included as an appendix to text.

Figure 1 - Precipitation Gauge Locations

Table 1

Precipitation Gauge	Recording Frequency	Maximum recorded value for interval							
		15-minute	30-minute	1-hour	2-hour	3-hour	6-hour	12-hour	24-hour
Palolo Fire Station	Irregular, converted to 15-min	0.76 †	1.40 †	2.25	2.89	3.35	4.37	6.55 †	8.01 †
Lyon Arboretum	hourly			2.34	3.05	3.91	5.37	7.97	8.89
Honolulu 0.5SSE [CoCoRaHS]	daily								7.79
Honolulu 2.0 SW [CoCoRaHS]	daily								8.24
Aloha Tower	Hourly			1.59	2.92	3.54	4.72	7.19	8.39

† Values based upon 15-minute data rolling totals

Discharge Gauge Analysis

Data from six stream gages across the basin, shown in Figure 2, were reviewed and compared to the latest available frequency analysis, which was derived from a rainfall-runoff and peak flow frequency hydrologic model that was weighted and compared to arrive at estimated peak flow discharges (See Table 2). Flows from Waihi Stream and Waiakeakua Stream were added together as the guagues are very near the confluence, and the reported frequency values are at the confluence. The frequencies were graphically compared to these computed discharge estimate curves, which are included in the Appendix. The observed flows ranged from approximately a 0.2 AEP (5-year) event to approximately a 0.45 AEP (~2-year) event.

It is noted that the USGS performed a flow measurement at the Woodlawn gauge on 12/8 during the recession of the storm event, and rating may be adjusted from previous values due to observed scour.

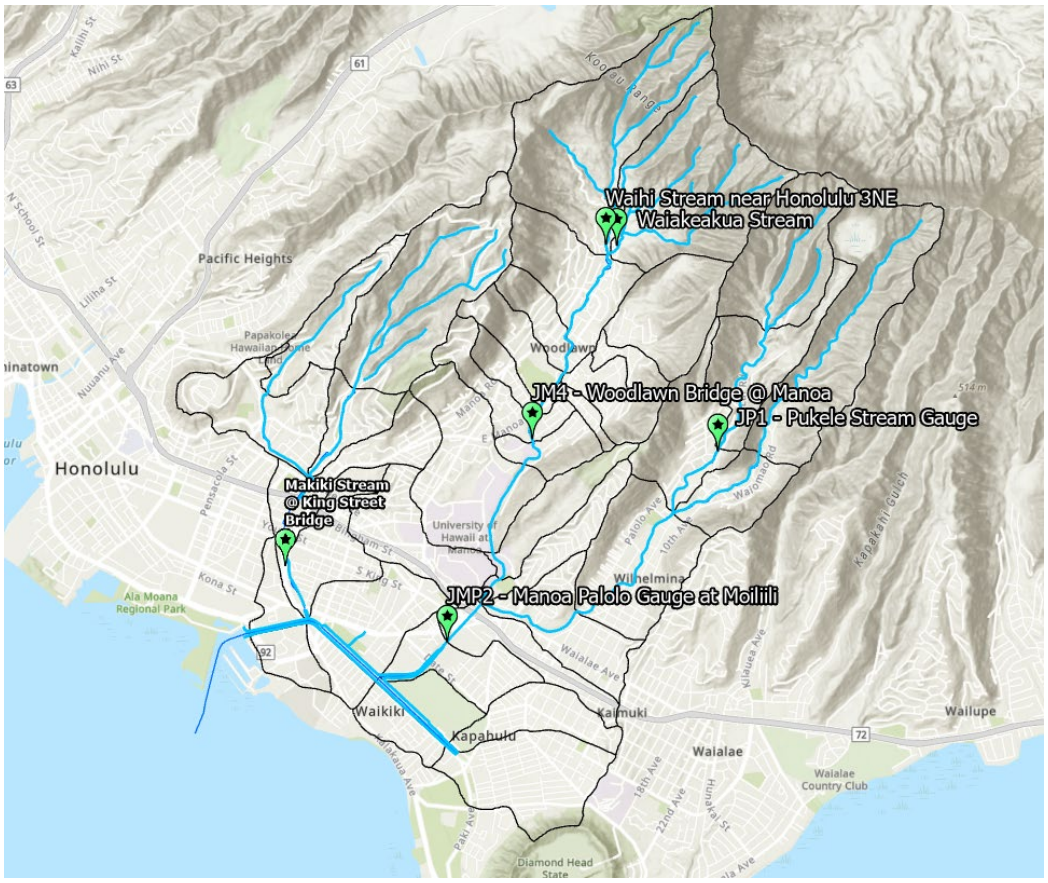

Figure 2 - Stream Gauge Locations

Conclusions

Based upon available news reports and social media posts, street flooding was the primary impact. Flooding also damaged the Iliwei Power Substation and an underground transmission cable, which is located just northwest of the watershed boundary, causing a power outage that affected much of the metropolitan area. Several water rescues also occurred. Precipitation and associated damages appear to be slightly greater in the Makiki watershed than the Palolo and Manoa watersheds.

The general range in precipitation frequency is consistent with the runoff frequency estimates. When considering both sets of data, characterization of the storm overall as a 0.20 annual exceedance probability ("5-year") event is a good estimate. The reports of primarily street flooding and minimal other damages also seems consistent with the estimated annual exceedance probability. Differences in estimated AEP between the observed precipitation and observed runoff peaks can be attributed to many things, including overall distribution of rainfall in time as well as antecedent conditions. It is understood that prior to this event that there had been a relatively long period of dry weather. Localized "point" totals at rain gauges may not accurately reflect the distribution of flow contributing to a particular stream gauge. Frequency analyses can and will change over time as more data becomes available and the period of record becomes more reliable.

Appendices

1. Hourly Precipitation records – Manoa Lyon Arboretum, Palolo Fire Station, Aloha Tower
2. Daily Precipitation Records – CoCoRaHS gauges
3. Atlas 14 Precipitation Frequency values for selected gauges
4. Discharge Frequency Curves for selected stream guages

[1] Precipitation frequency (PF) estimates in this table are based on frequency analysis of partial duration series (PDS).

Numbers in parenthesis are PF estimates at lower and upper bounds of the 90% confidence interval. The probability that precipitation frequency estimates (for a given duration and average recurrence interval) will be greater than the upper bound (or less than the lower bound) is 5%. Estimates at upper bounds are not checked against probable maximum precipitation (PMP) estimates and may be higher than currently valid PMP values.

Please refer to NOAA Atlas 14 document for more information.

[1] Precipitation frequency (PF) estimates in this table are based on frequency analysis of partial duration series (PDS).

Numbers in parenthesis are PF estimates at lower and upper bounds of the 90% confidence interval. The probability that precipitation frequency estimates (for a given duration and average recurrence interval) will be greater than the upper bound (or less than the lower bound) is 5%. Estimates at upper bounds are not checked against probable maximum precipitation (PMP) estimates and may be higher than currently valid PMP values.

Please refer to NOAA Atlas 14 document for more information.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

1. Introduction

The Ala Wai Canal General Reevaluation Study is a U.S. Army Corps of Engineers (USACE) is focused on evaluating flood risk management (FRM) alternatives to reduce flood and life safety risk in the Ala Wai Watershed. The nonfederal sponsor for this study is the State of Hawaii Department of Land and Natural Resources (DLNR). The study was authorized by Section 209 of the Flood Control Act of 1962 and the Flood Control Act of 1970 and was appropriated under the Supplemental Appropriations of the Bipartisan Budget Act of 2018. Additional information regarding the study can be found in the main report and report appendices.

This study finds that the NED plan provides average annual benefits of approximately of $48 million and has a benefit-to-cost ratio (BCR) of 2.5 at the current Fiscal Year 2023 (FY23) discount rate of 2.5 percent.

1.1. Purpose and Overview

The purpose of the economic appendix is to present the socioeconomic analysis completed to identify a recommended plan for a federal project as a result of the Ala Wai Canal General Reevaluation Study. The analysis follows the framework and methodology as directed by the USACE Planning Guidance Notebook (ER 1105-2-100) dated 22 April 2000 and the guidance listed in Section 1.4 below. The economic appendix includes the following:

- A description of the framework of the economic analysis including the major assumptions, data, methodologies, and analytical tools used
- A discussion of relevant background information including demographic, social, economic, and housing data for the study area
- A description of the flood risk analysis completed in terms of probability and consequence of flooding for the without-project (WOP) and with-project (WP) conditions for the study area. This includes the evaluation of flood damages in the study area on an equivalent annualized basis and calculates project performance by simulating a range of possible flood events, considering all pertinent economic and engineering data and risk and uncertainty parameters.

1.2. Location

The Ala Wai Watershed is located on the south side of the island of Oahu in urban Honolulu, Hawaii. The watershed includes the Makiki, Manoa, and Palolo streams, which all drain to the Ala Wai Canal. The two-mile-long canal was constructed during the 1920s to drain coastal wetlands and allow for the development of Waikiki. The watershed is characterized by steep mountain ridges on the northeast boundary near the Ko'olau Mountains that drain to the flatter portion of the watershed near Waikiki and eventually to the Pacific Ocean at Kahanomoku Lagoon and Kewalo Basin Harbor. The watershed encompasses 19 square miles, and a large portion of the watershed is susceptible to flooding.

1.3. Historical Background

On October 30, 2004, a thunderstorm moved from the east-northeast over the Ko'olau Mountains and into the Manoa Valley. Flash flooding occurred when peak rates of rainfall reached 1.29 inches in 15 minutes and 8.71 inches in 6 hours. The Manoa Stream overflowed its banks in several areas and debris above a bridge forced floodwaters out of the channel into residential areas and the University of Hawaii at Manoa campus. Historical archives were

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

destroyed, and instructional facilities and laboratories were damaged. The total damage estimate from the flood event was $85 million (unadjusted dollars), which includes damages to the university and approximately 120 homes. Several vehicles were also damaged.[1]

Significant flooding also occurred on Oahu in April 2018, and March 2021, and although the study area did not experience significant flooding, power outages associated with the storms affected residential areas in Palolo, Waikiki, Manoa, and Moilili.

1.4. Previous Studies

The Ala Wai Canal Flood Risk Management Feasibility Study was completed and the Chief of Engineers' report signed in December 2017. The Pre-construction, Engineering, and Design (PED) phase was funded by the Bi-Partisan Budget Act of 2018. During the PED phase, a validation report was completed. The validation report found that necessary modifications to the authorized project were not cost effective and lacked economic justification. The Ala Wai General Reevaluation Study was initiated in June 2021 to reevaluate the 2017 authorized feasibility study. This appendix documents the economic analysis for the Ala Wai Canal General Reevaluation Study.

1.5. Study Guidance

The analysis completed for this study is consistent with current regulations and policies. Pertinent guidance governing economic analysis procedures includes:

- Engineer Regulation (ER) 1165-217, Civil Works Review Policy, 1 May 2021
- Engineer Circular (EC) 1165-2-218 USACE Levee Safety Program, 22 Apr 2021
- Economic Guidance Memorandum (EGM) 01-03, Generic Depth-Damage Relationships, 4 Dec 2000
- Economic Guidance Memorandum (EGM) 04-01, Generic Depth-Damage Relationships for Residential Structures with Basements, 10 Oct 2003
- Economic Guidance Memorandum (EGM) 09-04, Generic Depth-Damage Relationships for Vehicles, 22 Jun 2009
- Engineer Manual (EM) 1110-2-1619, Risk-Based Analysis for Flood Damage Reduction Studies, 1 Aug 1996
- Engineer Regulation (ER) 1105-2-100, Planning Guidance Notebook, 22 Apr 2000
- Engineer Regulation (ER) 1105-2-101, Risk Assessment for Flood Risk Management Studies, 17 Jul 2017
- Engineer Regulation (ER) 1165-2-26, Implementation of Executive Order 11988 on Flood Plain Management, 30 Mar 84
- Institute for Water Resources (IWR) Report 96-R-12, Analysis of Nonresidential Content Value and Depth-Damage Data for Flood Damage Reduction Studies, May 1996
- Planning Bulletin (PB) 2019-04, Incorporating Life Safety into Flood and Coastal Storm Risk Management Studies
- Secretary of the Army (Civil Works) (SACW) POLICY DIRECTIVE – Comprehensive Documentation of Benefits in Decision Document, 5 Jan 2021
- Water Resources Development Act (WRDA) of 1990, Sec. 308 Flood Plain Management, 28 Nov 1990

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

1.6. The System of Accounts

Per the 5 January 2021 SACW POLICY DIRECTIVE – Comprehensive Documentation of Benefits in Decision Document, all USACE planning study project delivery teams (PDTs) must evaluate and provide a complete accounting, consideration, and documentation of the total benefits of alternative plans across all benefit categories. Total benefits involve a summation of monetized and/or quantified benefits, along with a complete accounting of qualitative benefits, for project alternatives across national and regional economic, environmental, and social benefit categories.

In computing total benefits of a project alternative, it is imperative that any benefits reflected in more than one category are only counted once. The level of detail will vary based on study type and the decision-context for the specific problems identified, recognizing that not all benefits can be monetized, and some cannot be cost-effectively quantified. Even if non-monetary measures are used, these benefits and impacts must be accounted for in the most substantive way possible.

Each study must include, at a minimum, the following plans in the final array of alternatives for evaluation:

1) The “No Action” alternative
2) A plan that maximizes net total benefits across all benefit categories
3) A plan that maximizes net benefits consistent with the study purpose
4) For flood-risk management studies, a nonstructural plan, which includes modified floodplain management practices, elevation, relocation, buyout/acquisition, dry flood proofing, and wet floodproofing
5) A locally preferred plan, if requested by a non-federal partner, if not one of the aforementioned plans

1.6.1. National Economic Development (NED)

Economic costs and benefits associated with an alternative are evaluated by measuring the impact the alternative will have on national wealth without regard to where in the United States the impact may occur. NED benefits must result directly from a project and must represent net increases in the value of the national economy. Equivalent annual damages and damages reduced (benefits) are calculated using a 50-year period of analysis and the current federal discount rate of 2.5 percent.

NED costs represent the costs of diverting resources from other uses in implementing the project as well as the costs of uncompensated economic losses resulting from detrimental effects of the project. NED annual benefits, the benefit-cost ratio (BCR), and the net NED annual benefits are calculated during the evaluation process. Net benefits represent the amount by which the annual NED benefits exceed annual NED costs, thereby defining the plan’s contribution to the nation’s economic output. A BCR of 1.0 or greater must be demonstrated for federal interest. The plan with the highest net benefits is considered the recommended NED plan, assuming technical feasibility, environmental soundness, and acceptability.

1.6.2. Regional Economic Development (RED)

Studies must quantify the regional economic impacts on local and regional income, employment, and other measures of the regional economy from the construction and operation of a project to the extent practical for each alternative. Where impacts are anticipated to be the

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

same across all alternatives or not play a significant role in the evaluation of alternatives and selection of a recommended plan, a qualitative assessment may suffice.

1.6.3. Other Social Effects (OSE)

Flood and coastal storm risk management reports must include an assessment of potential mortality (life loss) for the future without project (FWOP) condition and estimated changes in potential magnitude of mortality (life risk) for all alternatives in the final array. Where the change is anticipated to be the same across all alternatives or not play a significant role in the evaluation and selection of a recommended plan, a qualitative risk assessment will suffice. The residual risk to life safety must be determined for the recommended plan

Other relevant impacts to society must be described and analyzed in the most substantive manner possible, whether quantitative or qualitative. The analysis may present the same factor from multiple points of view. The analysis must describe groups that benefit from or are adversely affected by each alternative.

1.6.4. Environmental Quality (EQ)

For each alternative plan, positive and negative impacts to the environment must be analyzed in a manner consistent with current ecosystem restoration or environmental compliance guidance. The benefit assessment can be quantitative or qualitative and, if appropriate, monetized. The analysis must distinguish between national and regional benefits while ensuring benefits are not accounted for more than once.

2. Study Area

The study area, shown in Figure 1 below, is located on the south side of Oahu, Hawaii, and includes 19 square miles of highly urbanized land, including the commercial areas of Ala Moana and Waikiki and the industrial area near Kewalo Basin Harbor. The study area is part of the County of Honolulu and part of the City of Honolulu. The study area intersects 47 census tracts and is characterized by steep slopes through the residential areas along Makiki and Palolo streams that drain to the flatter land south of the H1 highway. The ground elevation changes from a few feet above average sea level near the confluence with the Pacific Ocean to approximately 800 ft (NAVD) at the upstream boundary.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Figure 1. Ala Wai Study Area Census Tracts

2.1. Land Use

The study area includes commercial, industrial, residential, educational, and government structures. The area is mostly built out and the only areas that are currently undeveloped are public parks. The National Land Cover Database (NLCD), which provides data on land use and land use changes, does not have data available for Hawaii.

2.2. Population and Socioeconomics

The total estimated population count in the study area was approximately 174,051 as of 2021[2]. The following figures display the distribution of the population by census tract, and other socioeconomic and demographic factors that impact the population at risk in the study area. Demographic data for the following maps was taken from the American Community Survey (ACS) 2017-2021 5-year estimates available on census.gov, unless otherwise indicated. Values for Census Tract 9821 are null since there are no households in this tract.

Figure 2 displays population count by census tract. The most populated tract is located around The University of Hawaii at Manoa, while the least populated census tracts are located along the coast of the Pacific Ocean, in Waikiki. It is important to note that Waikiki contains mostly

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

high-rise hotels and that there are approximately 100,000 tourists visiting Oahu per day which are not included in population census estimates.[3]

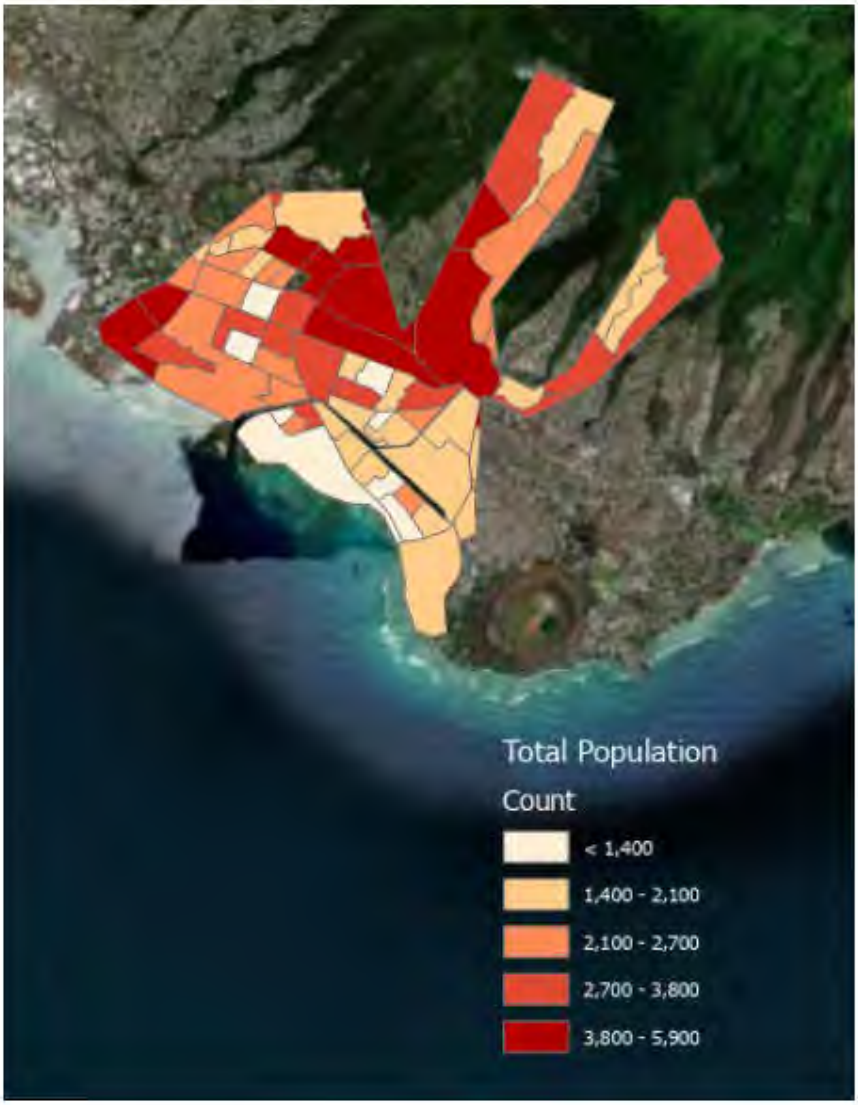

Figure 2. Population Count by Census Tract, ACS 2021 5-year Estimates

Figure 3 shows the Population Density in 2020, measured in persons per square mile. The tracts with the highest population density are located between Ala Wai Blvd and Ala Moana Blvd, and the tracts with the lowest population density are located near Makiki Heights, Woodlawn, Maunalani Heights, and Waikiki Beach. As previously noted, the daily influx of tourists in Waikiki Beach is not included in census data.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

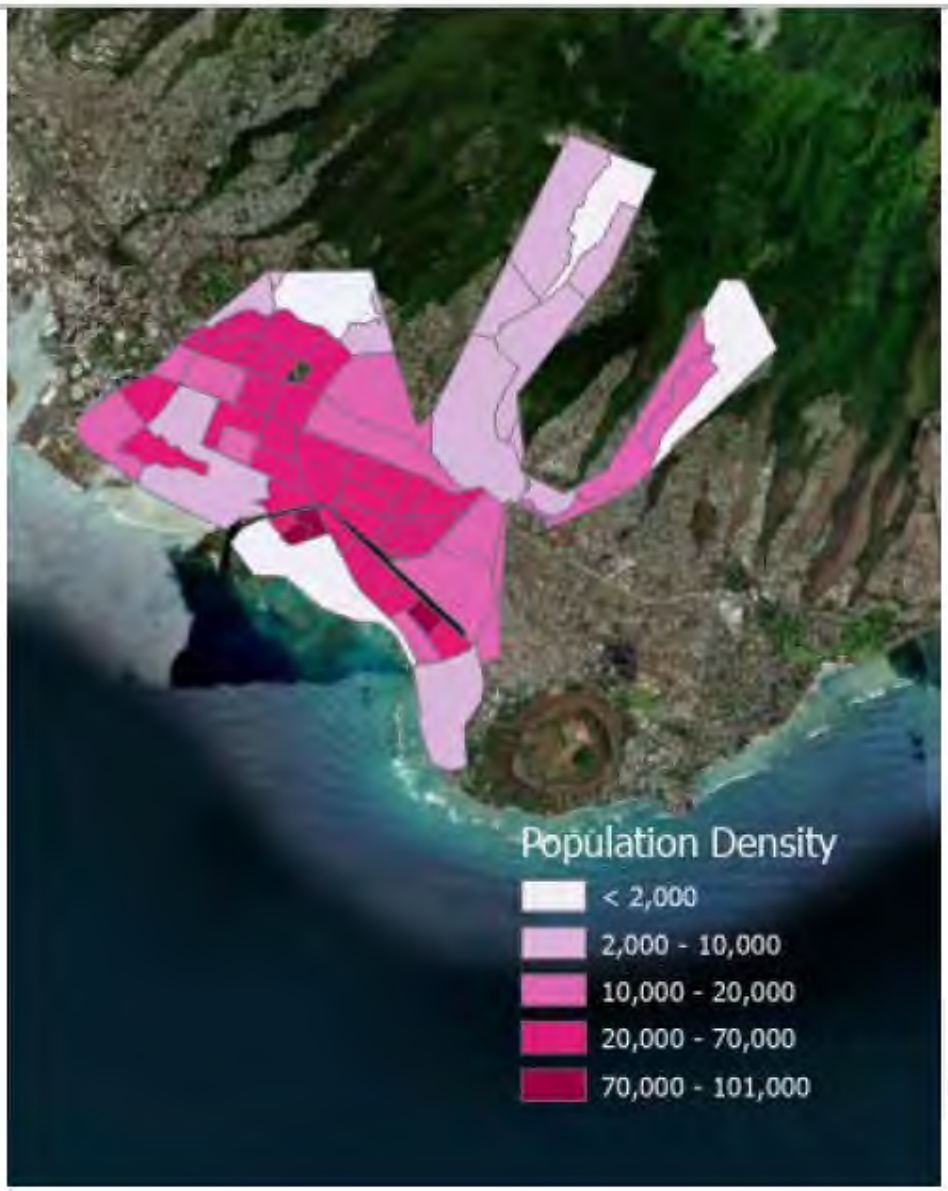

Figure 3. Population Density by Census Tract, ACS 202 5-year Estimates

Figure 4 displays median household income in 2021 inflation-adjusted dollars overlaid by average household size, by census tract. The average median household income by tract is $77,661 annually, while the lowest median household income is $21,522 and the highest median household income in a census tract is $154,044. Census tracts with the highest median income are located near Woodlawn and Makiki Heights. Census tracts with average median household income less than $50,000 don't contain many households and are near Ala Moana Center and Ala Wai Golf Course. Tracts with less than the average median household income are concentrated in Waikiki near the Ala Wai Canal, and in the neighborhood of Moilili. The average household size is two individuals. Larger households are located in the residential areas of Manoa and Palolo.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

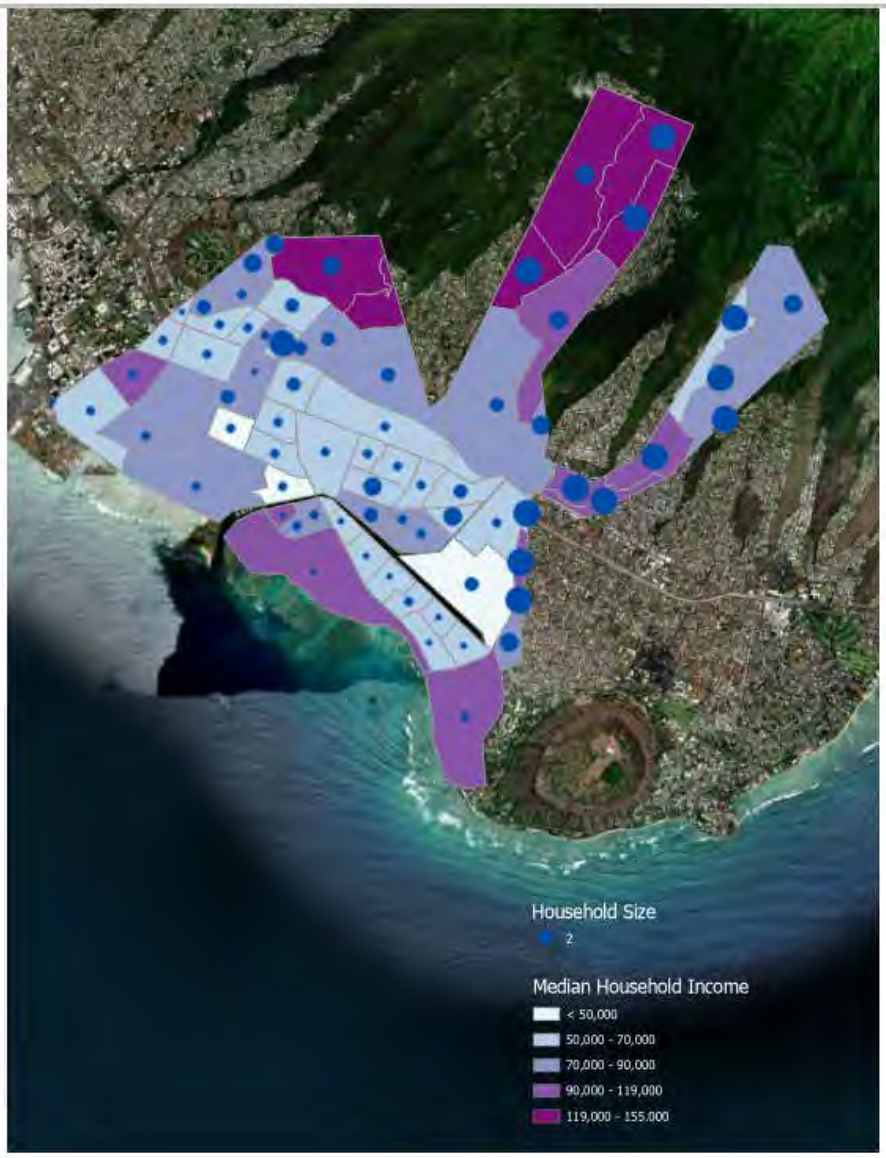

Figure 4. Median Household Income in 2021 Inflation-adjusted Dollars vs Household Size

Figure 5 shows the non-White population count by census tract. Census tracts with the highest non-White population are located near the University of Hawaii at Manoa and west of Ward Village.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Figure 5. Non-White Population Count by Census Tract, ACS 2021 5-year Estimates

Figure 6 shows the percent of the population that is older than 65 and may be more vulnerable in event of a flood than younger individuals who often can more easily evacuate. Areas with more than 30 percent of the population aged 65 or older include Makiki Heights, upper Manoa, upper Palolo, and coastal Waikiki. The census tract along the coastline in Waikiki contains many hotels, and hotel guests may have a range of ages that are not captured in census data estimates.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

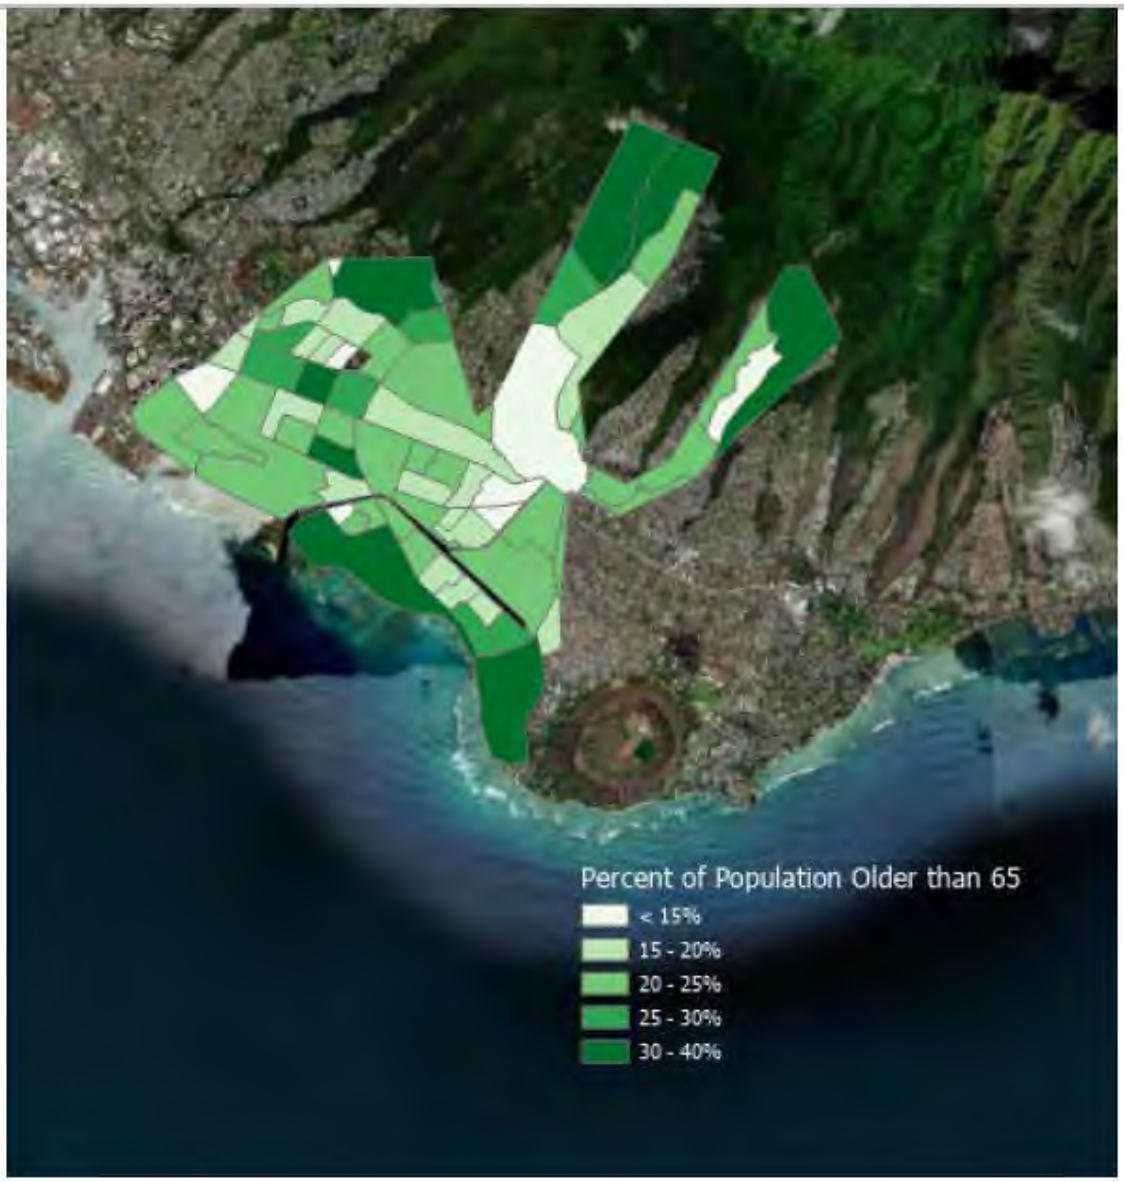

Figure 6. Percent of Population Age 65 or Older, ACS 2021 5-year Estimates

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Figure 7 displays the percent of the population under the poverty line by census tract. The poverty line for a household of four in Hawaii in 2021 was $30,480. The poverty rate in Honolulu in 2021 was approximately 12 percent. The highest poverty rate in a census tract in the study area is located just west of Makiki District Park, where 39 percent of the population was under the poverty line in 2021. The lowest poverty incidence occurs in the census tract just south of the National Memorial Cemetery, which has a poverty rate below one percent.

Figure 7. Percent of Population under Poverty Line by Census Tract, 2021 ACS 5-year Estimates

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

The Center for Disease Control computes a Social Vulnerability Index (SVI) based on demographic census data.[4] The SVI is represented as a percentile ranking in Figure 8, by census tract. Census tracts with a score of 0.90 are, on average, 90 percent more vulnerable than the rest of Hawaii, while census tracts with a score of 0.30 are 30 percent more vulnerable than the rest of the state. Census tracts that are lighter orange or yellow represent lower SVI scores, while census tracts that are darker orange or red represent higher SVI scores, indicating higher social vulnerability. The figure shows that there are socially vulnerable areas throughout the basin, especially along Highway 1. The neighborhoods of Woodlawn and Makiki Heights have lower social vulnerability scores, and median household income is also higher in these areas.

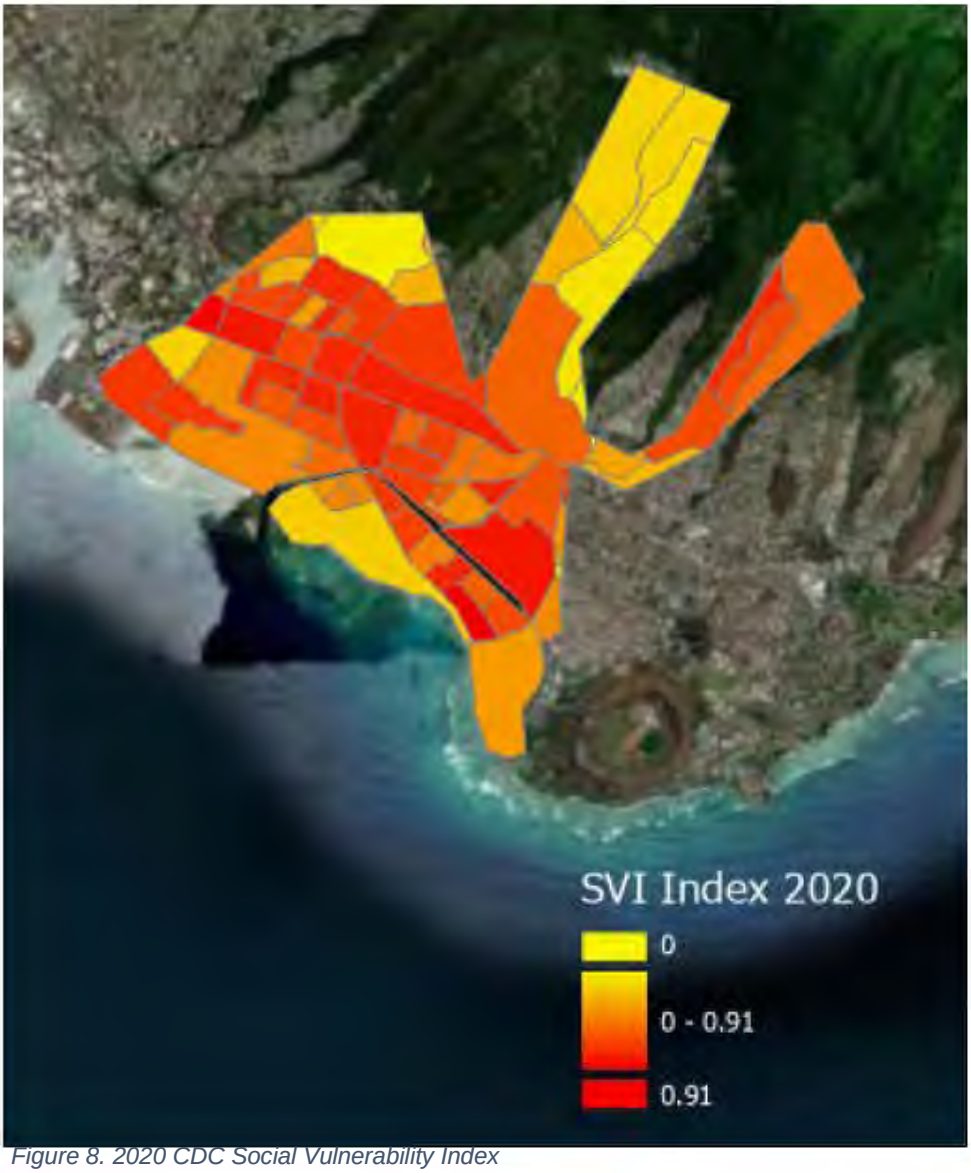

Figure 8. 2020 CDC Social Vulnerability Index

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

The following tables display demographic census data. Table 1 shows the population from 2010 and 2021 for Honolulu County (which encompasses the island of Oahu), the State of Hawaii, and the U.S.

Table 1. Study Area Population Trends

Geography	2010	2021	Percent Change 2010-2021
Honolulu County	936,984	979,682	5%
Hawaii	1,333,591	1,420,074	6%
U.S.	303,965,272	326,569,308	7%

Source: 2010 and 2021 ACS 5-Year Estimates

Table 2 shows the distribution of age and race for Honolulu County, Hawaii, and the U.S. A higher percentage of the population is above the age of 65 in Hawaii than in the U.S. In Honolulu County, the portion of the population that is Asian is near 61 percent, compared to 7 percent in the U.S. The percent of the population that is Native Hawaiian/Pacific Islander is nearly 25 percent in Honolulu County, compared to 0.4 percent in the U.S.

Table 2. Selected Population Characteristics

Demographic	Honolulu County	Hawaii	U.S.
Population	1,015,167	1,406,299	316,515,021
Percent 65 and above	17.8	19.1	16
Percent under 18	21.3	21.4	22.5
Hispanic or Latino (of any race), %	10.2	10.9	18.4
Two or more races, %	23.4	24.4	7
White, %	37.7	42.3	74.5
Native Hawaiian/Pacific Islander, %	24.8	26.3	0.4
Asian, %	60.8	56.3	6.9
All Other Non-White, %	10.1	10.1	25.6

Source: 2021 ACS 5-Year Estimates

Table 3 displays household demographics for Honolulu County, Hawaii, and the U.S. The median value of owner-occupied housing in Honolulu and Hawaii is more than 2.5 times the national average, and the median gross rent is more than 50 percent higher in Honolulu County and Hawaii than in the U.S. A higher percentage of households in Hawaii speak a language other than English at home, and the percentage of individuals with at least a bachelor's degree is slightly higher in Honolulu County than the rest of Hawaii and the U.S.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Table 3. Household Demographics

Demographic	Honolulu County	Hawaii	U.S.
Total Housing Units	367,126	556,937	139,647,020
Percent Owner Occupied	58.4	61	57.4
Median Value of Owner-occupied housing	$726,800	$662,100	$244,900
Median gross rent	$1,870	$1,755	$1,163
Average household size	2.96	2.95	2.6
Language other than English spoken at home (%)	26.8	25.9	21.7
Bachelor's degree or higher, percent of persons age 25+	36.2	34.3	33.7

Source: 2021 ACS 5-Year Estimates

Table 4 displays income demographics for Hawaii and the U.S. Although per capita and median household income are higher in Hawaii than the national average, housing costs are significantly higher in Hawaii. For example, the median home value in Hawaii is 7.5 times the median income, while this ratio is 3.5 for the U.S. The unemployment rate in Hawaii was slightly higher than that of the U.S. in 2021, and the poverty rate was near the national poverty rate.

Table 4. Income Demographics

Geography	Unemployment Rate 2021, %	Per Capita Income, last 12 months	Median Household Income, 2021 Dollars	Percent of Individuals Living Below Poverty
Hawaii	7.3	$39,045	$88,005	10.2
U.S.	6.3	$37,638	$69,021	10.7

Source: 2021 ACS 5-Year Estimates

3. NED Methodology

This section provides an overview of the economic analysis used to evaluate flood risk management alternatives to identify the NED plan. It includes a discussion of the models and inputs used to compute NED economic benefits.

3.1. Framework of Economic Analysis

3.1.1. Price Level, Period of Analysis, and Discount Rate

Values listed in this analysis are based on fiscal year (FY) 2023 price levels. Annualized benefits and costs were computed using a 50-year period of analysis and the FY 2023 federal discount rate of 2.5 percent. Annualized values are presented in thousands of dollars unless otherwise noted.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

3.1.2. Economic Analysis Model: HEC-FDA Program

The economic analysis uses the Hydrologic Engineering Center Flood Damage Analysis (HEC-FDA) software to compute damages. Economic damages serve as a basis for computing net economic benefits, and the BCR. HEC-FDA is a USACE-certified risk-based program and is standard for economic computations for FRM studies. HEC-FDA integrates engineering data (hydrologic, hydraulic, and geotechnical when applicable) and economic data (structure/content inventory and depth-percent damage curves) to model the potential flood risk for the WOP condition and study alternatives. HEC-FDA version 1.4.3 is used in this analysis.

ER 1105-2-101 requires incorporating risk and uncertainty in calculating damage estimates for flood events. This is best represented by a range of possible damage values and their likelihood of occurring, or a probability distribution. HEC-FDA uses Monte Carlo simulation to obtain a random sample of the contributing relationships and computes stage-damage functions, exceedance probability discharge curves, and conditional stage-discharge relationships to generate EAD values. EAD estimates capture the mean of the probability distribution of annual damage and are the basis for calculating equivalent annual damages and benefits. Uncertainty is incorporated into EAD estimates using Monte Carlo simulation; each iteration of a simulation randomly samples the uncertainty distributions, and the resulting values are used to transform the flow and stage distributions to a damage distribution. The area under the curve of the distribution is integrated to compute EAD. Thousands of iterations of this process are repeated to infer the EAD distribution and estimate EAD as the probability weighted average of all possible peak annual damages, where damage is a continuous random variable.[5] This process is depicted in Figure 9.

[5] This process is described in more detail in the HEC-FDA User's Manual Version 1.4.1 available at http://www.hec.usace.army.mil/software/hec-fda/documentation/CPD-72_V1.4.1.pdf and the HEC-FDA update notes Version 1.4.3 available at https://www.hec.usace.army.mil/software/hec-fda/documentation/HEC-FDA_ReleaseNotes_Jun2021.pdf.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

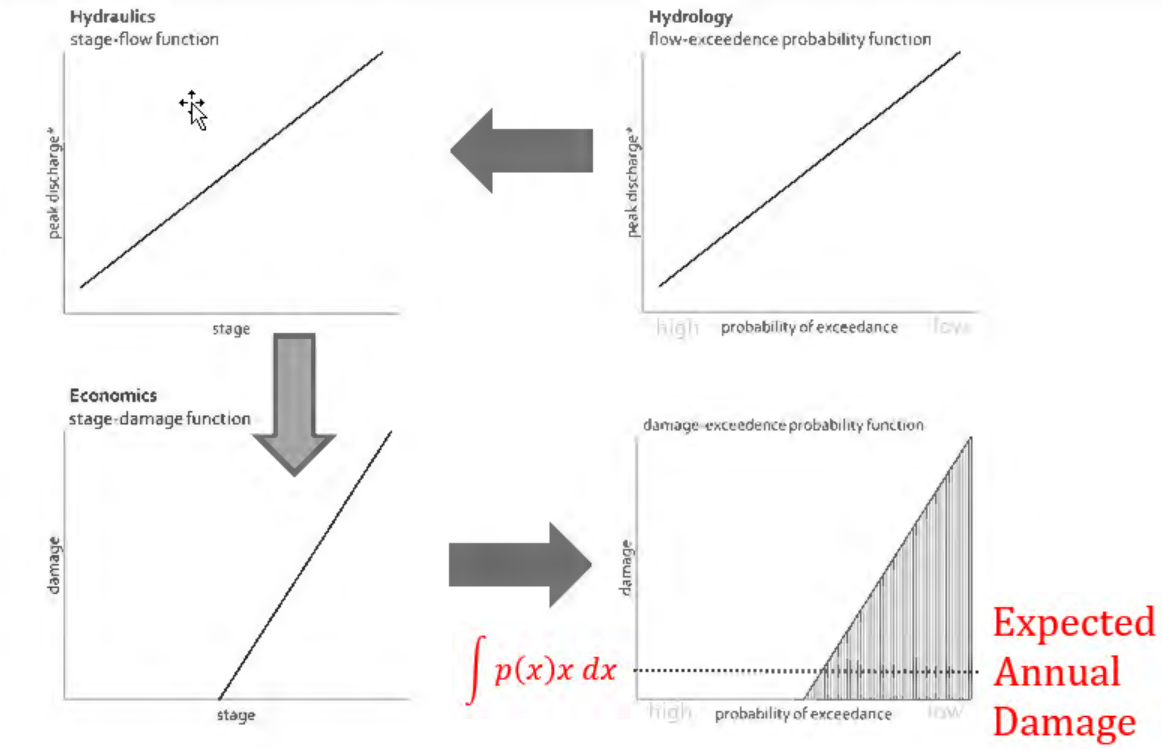

Figure 9. EAD Computation Process

To compute EAD values, HEC-FDA requires the following data:

1. **Structure Inventory Data** – This includes a structure identification number, a use category (industrial, commercial, single-family residence, etc.), stream location identified by cross sectional or grid data, first floor elevation, and depreciated structure and content values. This data was compiled using ArcGIS Pro 3.0, Spyder 5.2.1, and Microsoft Excel and was imported into HEC-FDA.

2. **Hydrologic and Hydraulic Data** – This data includes water surface profiles, exceedance probability discharge relationships, stage/discharge relationships, and levee fragility curves. Water surface profiles were developed in Hydrologic Engineering Center River Analysis System (HEC-RAS), processed in ArcGIS Pro and Excel to combine with the structure inventory and then imported into the HEC-FDA program.

   Gridded water surface elevations from the HEC-RAS model were assigned to structures at the structure location in ArcGIS Pro. Cross sections from the HEC-RAS model were selected to represent the discharge at each reach index station. These representative stations are referred to as reach index points throughout this appendix.

3. **Depth/Damage Functions for Structures and Structure Contents** – Depth-damage functions are used to calculate the percent damage a structure will incur at a specific water elevation in a flood event. Depth-damage functions and associated standard errors for residential structures and their contents were developed by the Institute for Water Resources (IWR) and published in *Economic Guidance Memorandum 04-01: Generic Depth-Damage Relationships for Residential Structures with Basements, October 2003.* The depth-damage functions and standard error estimates are based

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

upon previous damages that occurred during flood events in the United States. Depth-damage functions for multi-family residential structures and non-residential structures were obtained from the URS Group's expert elicitation report *Solicitation of Expert Opinion Depth-Damage Function Calculations for the Benefit-Cost Analysis Tool, October 2008.*

4. **Risk and Uncertainty Parameters** – Uncertainty parameters discussed in Section 3.2 of this report were also entered into HEC-FDA.

Discharge-exceedance probability, stage-discharge, and stage-damage functions derived at a damage reach index location are used to compute the damage-exceedance probability function. Monte Carlo simulation is a computationally efficient method of obtaining the damage-exceedance probability function due to uncertainty in input parameters. This numerical integration process requires all these relationships, and risk and uncertainty parameters be input into HEC-FDA. EAD values are obtained from the cumulative distribution function produced in successive iterations of the Monte Carlo simulation process.

3.1.3. Primary Sources of Uncertainty

Uncertainties are accounted for in the HEC-RAS model (see Appendix A, H&H Engineering) and in the HEC-FDA portion of the analysis. The primary sources of uncertainty present in the calculation of economic damages include storm water discharge, water surface elevations, levee performance, structure elevations, structure and structure content values, and depth-damage relationships. These are described in more detail below.

1. **Levels of Storm Water Discharge –** The amount of rainfall from storm events with equal probabilities can vary by location throughout the watershed. Variability in storm intensity, elapsed time during rainfall, ground permeability, soil, ambient temperature, and other physical factors can also cause variation in the location and timing of rainwater entering the channel. This variation causes uncertainty in the level of storm water discharge at any location along the river.

   In addition to natural variation arising from physical factors, there is uncertainty in the modeling of water discharges for a storm event due to limited historical meteorological and stream gauge data. This data can often be incomplete or limited in sample size (length of record for time-series data). Discharge-probability distributions in this study were computed using the graphical method and were based on a period of record length of 50 years. For additional information on the period of record, refer to Appendix A (H&H) of this report. HEC-FDA calculates 95 percent confidence intervals for storm discharges that are used in economic computations.

2. **Water Surface Elevation –** River bathymetry, water temperature, debris, and obstructions in the channel can affect the water surface elevation for a specific location along the river. When the water surface elevation exceeds the top of the bank elevation, water flows onto the floodplain. Thus, uncertainty affects water surface elevations in the floodplain and in the channel. To address this uncertainty, a standard deviation with standard normal distributions were input into HEC-FDA for water surface elevations. A standard deviation of 0.5 feet, held constant at the 2% annual exceedance probability (AEP) event was used.

3. **Levee Performance –** There is uncertainty about how an existing levee will perform under certain water surface elevations, how interior water-control facilities will perform,

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

and the thoroughness of closures or openings in an existing levee. For this analysis, top of bank elevations were used without geotechnical failure functions.

4. **First Floor Elevations –** Structure elevation is key in determining the depth of flooding inside of a structure during a flood event. First floor structure elevation is the aggregate of topographical elevation and foundation height. Both elevations are prone to uncertainty. Uncertainty in topographical and foundation height varies by the survey methodology and resolution, and foundation height uncertainty varies by surveying methodology. Statistical uncertainty was determined by referencing the standard deviation estimates contained in EM 1110-1-1619, which presents standard deviation of error estimates for various measurement methods, based on Institute for Water Resources (IWR) research. First floor elevations were derived by combining terrain elevation at the structure location with structure foundation height. Foundation heights used were obtained from the National Structure Inventory (NSI) 2022 data. Structures were assigned standard deviations of error for first floor elevations of 0.60 feet, based on requirements for aerial survey with 5-foot contour data. It is assumed that joint distribution error and corresponding probability distribution functions are normally distributed with a mean error of zero.

5. **Depreciated Structure and Content Replacement Values –** The depreciated replacement values for structures and contents are used to determine economic damages in the floodplain and are a function of structure type, condition, and size. Since surveying every structure in the floodplain was not feasible for this study, there is uncertainty in estimated values. Depreciated structure values were taken from the NSI 2022 data. Structures that existed in state parcel data that were not included in the NSI were added to the NSI data and were surveyed in Google Earth Pro to determine structure type, condition, and foundation height. Square footage was calculated in Google Earth Pro for these structures and multiplied by the RS Means square foot value to obtain the depreciated replacement cost.

   Errors for structure value estimates are assumed to be normally distributed with a mean error of zero, and standard deviations range from 10 to 15 percent of mean structure value. Structure content values are estimated as a percentage of the structure value, based on structure type and the depth-damage function.

6. **Depth-Damage Relationships** – Depth-damage functions are used to calculate the percent damage a structure will incur at a specific water elevation in a flood event and is subject to uncertainty. The methodology used to construct depth-damage relationships for non-residential structures was developed by an expert-opinion elicitation process, conducted by the URS Group and published in the report *Solicitation of Expert Opinion Depth-Damage Function Calculations for the Benefit-Cost Analysis Tool, October 2008.* This report provides non-residential depth-damage curves for structure contents by structure type as well as content-to-structure value ratios (CSVRs) and associated standard errors.

   Depth-damage functions and associated standard errors for single family residential structures and their contents were developed by the Institute for Water Resources (IWR) and published in Economic Guidance Memorandum (EGM) 01-03*: Generic Depth-Damage Relationships.* The depth-damage functions and standard error estimates are based on previous damages that occurred during flood events in the United States.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

For high-rise residential structures with more than 20 units, Prototype 4A depth-damage curves published in *North Atlantic Coast Comprehensive Study (NACCS) Resilient Adaptation to Increasing Risk Physical Depth Damage Function Summary Report, January 2015,* were used. The Prototype 4A category includes high-rise structures in urban areas that are subject to inundation only and exclude coastal storm surge and erosion. Since no residential-specific curves were available for high-rise apartments, the NACCS Prototype 4A curves were used. It should be noted that most high-rise residential structures in the study area have retail/commercial areas on the first floor.

Depth-damage functions for other damage categories are described in the discussion of damages by category in the following sections.

3.1.4. Economic Damage Reaches and Index Stations

The study area was divided into 14 damages reaches based on similar topography, hydromorphology, hydraulic characteristics, and plan formulation measures. Figure 10 depicts study area reach boundaries.

Figure 10. Study Area Reach Delineation

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Each reach is associated with an index station, which is used to specify discharge-probability, stage-discharge, stage-damage functions, and top of bank elevations for each reach. The index station assignments are based on hydrologic parameters and hydraulic conditions specific to each reach. The assigned index station is generally representative of the conditions throughout the reach. Terrain elevations increase quickly throughout the study area, particularly in reaches AW7 through AW9. In these reaches, the index station is less representative of the changing conditions throughout the reach. Since there are multiple streams within the study area, station numbering in each reach reflects the station numbering associated with the stream in that reach. Table 5 presents reach index and downstream/upstream cross section information for the study area.

Table 5. Ala Wai Reach Index Stations

Reach	DS_XS	US_XS	Index Station	Stream
AW1	67	10082	3282	Ala Wai
AW2R	76	4709.5	1897	Makiki
AW2L	76	4709.5	1897	Makiki
AW3R	2	4372	943	Kanaha
AW3L	5940.67	9543	7672	Makiki
AW4	2961	5770	5195	Ala Wai
AW5	6095	10082	7405	Ala Wai
AW6	305	4653	2609	Palolo
AW7R	1457	8016	7839	Manoa
AW7L	84	2891	1107	Manoa
AW8R	8117	16506	10496	Manoa
AW8L	3042	16506	10968	Manoa
AW9R	6282	15526	10074	Palolo
AW9L	6282	15526	11542	Palolo

3.2. Data Development

3.2.1. Structure Inventory

The structure inventory for the HEC-FDA model was based on the 2022 NSI data available at https://www.hec.usace.army.mil/confluence/nsi. The data includes parcel footprints with several attributes that are a combination of HAZUS, Census Bureau, CoreLogic, FEMA, and USGS data. To develop the structure inventory used in this study, the NSI data was clipped to the 0.2% AEP study area boundary in ArcGIS Pro and converted to a point feature class. Hawaii State parcel data was overlaid in GIS on the NSI data to verify accuracy of NSI data structure location and identify structures that weren't included in the NSI data. Structures that needed to be added to the NSI data were manually surveyed in Google Earth Pro to obtain occupancy type, structure square footage, and foundation height, and were added to the NSI dataset. Depreciated replacement values for the 95 added structures were calculated using RS Means (NSI) values per square foot for a specified occupancy type. Topographic elevations at the structure location for all structures were extracted from the terrain data used in the HEC-RAS

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

model in ArcGIS Pro. Occupancy types in the NSI data reflecting basements were changed to no basements, to be representative of the study area. The average number of stories for structures in the studies area is 3.7.

It should be noted that there are differences between the current structure inventory data and the structure inventory used in the 2021 validation report and the 2016 feasibility study. The validation report indexed 2016 structure values to current price levels, and then randomly assigned structure location (xy coordinates) to structures, stratifying by reach. It was determined that the validation report structure inventory was less accurate than the 2022 NSI data and that several structures were not included in the 2021 validation report or the 2017 feasibility study, including in the area south of the University of Hawaii at Manoa, the commercial area of Ala Moana, and the commercial area near Kewalo Basin Harbor. These structures are high-value structures that are susceptible to flooding, and as a result, aggregate structure value and flood damages will be higher in this report than in the previous two reports. Additionally, the average depreciated replacement value for residential structures used for the 2017 feasibility study and the validation report was much lower than this Reevaluation Report. Lastly, the depth at structure locations across the study area was 0.86 and 0.83 ft for the 2017 feasibility study and validation report, respectively, and was 1.3 feet in this study, for the 0.2% AEP event FWOP condition, which results in higher FWOP damages.

Section 308 of the Water Resources Development Act (WRDA) of 1990 has been observed in this analysis. Google Earth historical imagery from 1985 confirms the study area was completely built out prior to 1991.

3.2.2. Damage Categories and Structure Occupancy Types

A structure occupancy type in HEC-FDA is a subgroup of a damage category that is used to associate structures with depth-percent damage functions, first floor uncertainties, structure value uncertainties, and content values and uncertainties. The tables below display summaries of the structure inventory and uncertainties associated with damage categories and their occupancy types.

Table 6 shows the structure count by damage category and depreciated structure replacement and content values for each category. Residential buildings account for the largest portion of structures in the study area, while commercial buildings account for the highest aggregate depreciated structure and content values. Total depreciated structure value is nearly $12 billion and depreciated content value exceeds $3 billion.

Table 6. Structure Inventory Summary FY23 PL ($000)

Damage Category	Structure Count	Depreciated Structure Value	Depreciated Content Value
Residential	3,464	$5,498,736	$1,075,916
Commercial	2,081	$5,595,682	$1,631,742
Industrial	163	$137,109	$57,586
Public	171	$489,345	$271,847
Total	**5,879**	**$11,720,873**	**$3,037,091**

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Table 7 displays damage categories and associated standard deviations for structure values, which were imported into HEC-FDA with depth-damage curves.

Table 7. Structure Value Uncertainty

Damage Category	Description	Normal Distribution Std Dev (%)
RES	Residential	17.00
PUB	Government, Educational, Religious	13.00
COM	Commercial	11.00
IND	Industrial	11.00
EMG	Emergency costs	50.00
CLN	Cleanup Costs	57.60
AUTO	Vehicles	34.18

3.2.3. Structure Content Valuation

The content-to-structure value ratios (CSVRs) associated with the generic content depth-damage curves for residential structures provided in Economic Guidance Memorandum (EGM) 01-03, *Generic Depth-Damage Relationships* were used for single family residential structures in HEC-FDA. These relationships calculate content value as a percentage of structure value, based on occupancy type. CSVRs for nonresidential structures were taken from the URS Groups' *Solicitation of Expert Opinion Depth-Damage Function Calculations for the Benefit-Cost Analysis Tool, October 2008,* and are shown below in Table 8.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Table 8. Occupancy Types and Content-to-Structure Value Ratios

Occupancy Code	Description	CSVR
RES1	Single Family Residential	100.0
RES3A-RES3F	Multi-Family Residential	9.9
RES4	Hotel	25.6
RES5-RES6	Nursing Home	60.4
COM1	Average Retail	34
COM10	Garage	66
COM2	Average Wholesale	70
COM3	Average Personal & Repair Services	66
COM4	Average Professional Technical Services	18.1
COM5	Bank	18.1
COM6	Hospital	43.9
COM7	Average Medical Office	60.4
COM8	Average Entertainment	24.6
EDU1	Average School	6.5
EDU2	Average University	6.5
GOV1	Average Government Services	24.6
GOV2	Average Emergency Response	69.5
IND1-IND2, IND4-6	Industrial Light	38.2
IND3	Warehouse	35.6
REL1	Religious Facilities	6.9

3.2.4. Depth-Damage Functions: Residential

Depth-damage curves relate the percent of structure and content value that is damaged given the depth of inundation and include uncertainty. As noted above, the depth-damage functions and associated standard deviations developed for EGM 01-03, *Generic Depth-Damage Relationships,* were used for single family residential structures. Basements are very uncommon in Hawaii due to the risk of flooding from hurricanes and rivers, high water tables, and mild climate. Additionally, no surveyed structures contained basements, therefore residential depth-damage functions used were for structures without basements. Depth-damage functions are shown in Table 9 for one-story structures.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Table 9. One Story, No Basement Residential Depth-Damage Function

Depth	Mean of Damage	Standard Deviation of Damage
-2	0%	0.0%
-1	2.5%	2.7%
0	13.4%	2.0%
1	23.3%	1.6%
2	32.1%	1.6%
3	40.1%	1.8%
4	47.1%	1.9%
5	53.2%	2.0%
6	58.6%	2.1%
7	63.2%	2.2%
8	67.2%	2.3%
9	70.5%	2.4%
10	73.2%	2.7%
11	75.4%	3.0%
12	77.2%	3.3%
13	78.5%	3.7%
14	79.5%	4.1%
15	80.2%	4.5%
16	80.7%	4.9%

3.2.5. Depth-Damage Functions: Nonresidential

The depth-damage functions used for multifamily structures and nonresidential structures and contents are based on the 2008 URS Group draft report *Solicitation of Expert Opinion Depth-Damage Function Calculations for the Benefit-Cost Analysis Tool*. Twenty-one core nonresidential structure types were evaluated by a panel of experts from across the United States using historical flood damage data. The resulting data from the panel included nationally relevant depth-damage functions for use in estimating the value of damages from flooding to commercial, industrial, and public structures nationwide. For high-rise residential structures with more than 20 units, the depth-damage curves for Prototype 4A in the *North Atlantic Coast Comprehensive Study Resilient Adaptation to Increasing Risk Physical Depth Damage Function Summary Report, January 2015,* were used. For nonresidential structures, depth-damage function uncertainties are expressed as a triangular distribution.

Note that published depth-damage functions were edited to exclude damage percentages at depths less than zero. This was to avoid erroneously calculating damages for negative depth changes due to noise in the water surface elevation grid cells, and is appropriate for the study area since structures don't have basements. Damage percentages start interpolating from zero feet of depth.

3.2.6. Other Damage Categories

In addition to damages to structures and contents, other damages generally occur in a flood event, and include cleanup costs, other public assistance, and damage to vehicles. This section

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

explains these categories in more detail and justifies them as flood damage reduction categories that are included in the calculation of with project benefits.

3.2.6.1. Cleanup Costs

ER 1105-2-100 provides for emergency expenses, which include hazardous and toxic waste cleanup, to be included in damage estimates for flood events. Structures that are inundated in a flood event require post-flood cleanup to remove floodwater, sediment, debris, mold, mildew, and toxins. These cleanup costs are considered a damage category in the calculation of with project benefits and can vary based on the depth of flooding. A depth-damage curve is used to estimate the cost incurred for a given level of inundation in a structure. The depth-damage function for cleanup costs and the maximum value of $19,000 for cleanup costs was derived from online estimates of natural flood damage remediation costs in Pearl City, Oahu, near the study area[6]. The percent damage for a specific depth was calculated by dividing the cleanup cost associated with each depth by the total cleanup cost for the max depth. A structure incurs the maximum cleanup cost when it is inundated with nine feet of water or more. A structure incurs 41 percent of the maximum cleanup cost up to four inches of floodwater, and 79 percent of the maximum cost when between four and eight inches of floodwaters are present.

3.2.6.2. Emergency Costs

Other emergency costs incurred in flood events were calculated by using FEMA's Individuals and Households Program data for DR-4365-HI, which included the flooding on Oahu in April 2018. This data includes the following: Public Assistance (PA) to aid in public debris removal, emergency protective measures, and repair of roads, bridges, water facilities, public buildings, utilities, public parks, and recreation facilities; and Other Needs Assistance (ONA), which includes aid to replace essential household items and moving, storage medical, dental, and funeral expenses caused by the flood. Housing assistance is not included in the analysis.

Actual PA and ONA claims data was gathered from FEMA's website for DR-4365-HI and used to calculate maximum emergency cost values[7]. PA per household was calculated by taking the total sum of public assistance and dividing it by the number of Individual Assistance Applications approved. As of November 2022, nearly $4.5 million in public assistance emergency work grants had been obligated, and 252 individual assistance applications had been approved for IHP. This resulted in a PA per household amount of $17,946. Other needs assistance from this storm event totaled $300,000 as of November 2022 and is based on 252 approved claims. Average ONA per household was calculated to be $2,847. This was added to the PA per household amount for an emergency cost amount of $20,794.

Emergency costs are assigned a depth-damage function that associates a specific depth of flooding to a percentage of the emergency costs in HEC-FDA. Fifty percent of the total value of emergency costs are incurred when water surface elevations are greater than 0.5 feet, while water surface elevations of one foot or greater incur 100 percent of the emergency cost value. This assumes that households must incur a depth of flooding greater than zero to be eligible to file a claim. Thus, structures which are inundated one foot or more above the first-floor elevation would incur public and other needs assistance related costs reflected in the FEMA claims data.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

3.2.6.3. Vehicle Costs

This economic analysis includes vehicle damages for vehicles at residential structures. Historically, vehicles on Oahu have been trapped in flash flooding from localized rain events and have been inundated with mud and water during major storms. Vehicle damages are calculated as a function of the number of vehicles per residence, estimated average value per vehicle, and the depth of flooding above the ground elevation.

To obtain the vehicle replacement value, the average number of available vehicles per household in Honolulu County was taken from the 2021 American Community Survey 1-year estimates available at census.gov. A weight was then calculated based on the percent of households with zero to five cars per households. The weighted average of cars per household was 1.77. Average vehicle cost was calculated by taking the average cost of vehicles posted on Auto Trader, a website for used vehicles. The average used car value from the sample was $30,646, which was multiplied by 1.77 to calculate the total value per household. This total of $54,245 was then multiplied by 0.5 in accordance with EGM 09-04 Table 5 to account for 50 percent of the vehicles being removed from the floodplain with an estimated warning time of six hours or less. The final vehicle replacement value per household is $27,122 and is used in HEC-FDA to calculate auto damages.

Depth-damage functions and associated standard deviations for vehicle damages were taken from EGM 09-04, *Generic Depth-Damage Relationships for Vehicles.* The maximum damage value of $27,122 is applied when flood depths reach seven feet or more.

3.3. Damage Analysis Modeling

Damages modeled in HEC-FDA are the basis for calculating net NED benefits. The structure inventory including values, elevations, depth-damage relationships, and uncertainty parameters, were imported into HEC-FDA along with water surface profiles to compute damages. HEC-FDA damages include physical inundation damages to commercial, industrial, residential, and public structures, and damages to contents and vehicles.

3.3.1. Model Hydraulic and Hydrologic Inputs

Water surface profiles were modeled in HEC-RAS for the FWOP, future with-project (FWP), existing WOP, and existing WP conditions for analysis years 2030 and 2080. Events included in the water surface profiles include the 50%, 20%, 10%, 5%, 2%, 1%, 0.5%, and 0.2% AEP events. Water surface profiles were developed for the base and future years for the without-project condition and for the base and future years for three alternatives.

Gridded raster data from HEC-RAS was spatially joined to structures using ArcGIS Pro 3.1. Each grid cell represents a numbered “station” that is associated with a structure in HEC-FDA. In addition, water surface profiles for reach index stations were included in HEC-FDA. Reaches were spatially joined to structures in ArcGIS and the geospatial reach assignment was used in HEC-FDA to aggregate damages.

Geotechnical functions were not developed for the FDA models since there are no reaches with a potential levee failure.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

3.3.2. Exceedance Probability-Discharge Functions

Exceedance probability-discharge functions are generated from water surface profiles for each geometry, reach, and analysis year. In this FDA model, the graphical method was used to generate probability-discharge functions. Uncertainty was computed using an Equivalent Record Length (N) of 50 years, based on the hydrology from the Validation Study and a series of discussions between the RMC, HEC, the hydrologist, and the economist. This is documented in Appendix B of this report. The “Less Simple” method of Order Statistics was used to approximate uncertainty with a standard normal distribution. Since HEC-FDA 1.4.3 was used, 173 points were included in the standard probabilities for graphical probability functions.

3.3.3. Stage-Discharge Functions

A stage-discharge function is the relationship between the discharge at a river cross section and the water surface elevation produced by that discharge. Stage-discharge functions were retrieved from the RAS output and entered in FDA for each geometry, reach, and analysis year. The probability density function defining uncertainty for the stage-discharge relationship was specified by a normal distribution with a standard deviation of 0.5 feet, held constant at the 10% AEP event.

4. Without-Project NED Analysis and Results

4.1. FWOP Condition

This section describes damages that are expected to occur in the absence of a Federal project in the study area. These damages include damages to structure and structure contents, and other damages, which include vehicle damages, cleanup costs, and emergency costs associated with flooding. Without-project flooding also impacts OSE, which includes loss of life and impacts to tourism, and is quantified in this section.

HEC-FDA software was used to calculate economic damages for this study. Expected annual flood damages are the basis for calculating WP benefits and are vital to the evaluation of the project. Expected annual damages are equal to the mean of all possible values of damage that are derived through Monte Carlo sampling of discharge-exceedance probability relationships, stage-discharge relationships, and stage-damage relationships and their uncertainties. This section presents EAD as estimates due to the time-dependent variance in hydrologic, hydraulic, and economic data. Uncertainty parameters for the exceedance-probability and stage-discharge relationships are described in Section 3.

Without-project conditions for base and future years were developed in HEC-RAS and modeled in HEC-FDA for the study area.

4.2. FWOP Flood Extent

The WOP analysis results are based on RAS raster outputs of the flood extent and depth of flooding, and the spatial relationship between floodwaters and structures. Flood extents for the 10%, 2%, 1%, and 0.2% AEP events for the study area are shown below.

Figure 11 shows the flood extent for the 10% AEP event. Significant flooding from frequent events occurs in reaches AW1, AW2L, AW2R, AW4, AW5, AW7L, AW7R, and AW8L.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

4.3. Flood Risk: Probability and Consequences

4.3.1. FWOP EAD

Expected annual damages are the estimated consequences of flooding on an annual basis considering a full range of flood events. FWOP EAD are shown in the following tables by reach and damage category.

Table 10 displays the FWOP EAD to structures and structure contents by reach. Aggregate damages are highest in reach AW1 and exceed $28 million. Total FWOP EAD for structures and structure contents are nearly $70 million. Note that Reach AW5 contains the golf course and only two structures. Floodwaters in reach AW9L floodwaters are generally contained in the channel, resulting in a very narrow overbank flood extent and damages near zero.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Table 10. FWOP EAD (Structures and Contents)

Reach	Residential	Commercial	Industrial	Public	Total
AW1	$18,421	$9,808	$120	$181	$28,530
AW2L	$2,887	$489	$50	$108	$3,534

AW9R	$1,411	$247	$0	$19	$1,677
Total	**$38,172**	**$27,565**	**$897**	**$3,337**	**$69,971**

Note: values in $000s; FY23 price level

Table 11 displays damages to vehicles, and clean-up and emergency costs that are incurred as the result of flooding. Damages to vehicles exceed $30 million in all reaches. Clean-up costs account for over $700,000 in EAD in all reaches, and emergency costs account for over $1.6 million in EAD in all reaches. Total FWOP EAD in the study area is nearly $100 million.

Table 11. FWOP EAD (Other Categories)

Reach	Auto	Clean-Up	Emergency	Total
AW1	$15,144	$130	$292	$15,566

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Table 12 displays the number of structures damaged by the 10%, 20%, 1%, and 0.2% AEP events by reach, and the damages associated with each event and reach. Total estimated damages for the 0.2% AEP event is $1.3 billion. Approximately half of these damages occur in reach AW1, where there are high value commercial, apartment, and hotel buildings. Thirty percent of all structures damaged by the 0.2% AEP event are in reach AW1. Damage estimates shown exclude damages to vehicles, emergency costs and cleanup costs.

Table 12. Structure Count and Damages by Event and Reach

4.3.2. Future Without-Project Performance by Reach

Project performance statistics help inform the risk of a specific frequency flood event. Three components are indicators of project performance: AEP, long-term exceedance probability (LTEP), and conditional non-exceedance probability (CNEP). AEP is the likelihood flooding occurs in any given year. LTEP is the probability that flooding occurs in a period of 10, 30, or 50 years. CNP, also called assurance, is the probability that flooding does not occur, conditional on a flood event of 2%, 1%, or 0.2% annual frequency occurring.

AEP represents the probability of any event equaling or exceeding a specified stage in any given year. When levees are present, the stage is the top of levee or effective top of levee specified by geotechnical fragility curves. When levees are not present, which is the case in this study, the top of bank elevation is used. In non-leveed reaches, the target stage is determined by the exceedance of a percentage of the mean damage associated with a specified event. The default criteria of five percent of the total damage for the 1% AEP event was used for this study. The following table displays the project performance statistics for the FWOP condition.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Table 12 shows performance statistics for the FWOP condition. All reaches except for AW3R, AW4, AW6, AW7R, and AW9L have a high probability of flooding in any given year. The probability that banks are overtopped in 30 or 50 years is nearly 100 percent in all reaches except for AW9L. Correspondingly, assurance is low in all reaches except AW9L, where the probability that no flooding occurs given the occurrence of a 2% AEP event is nearly 1.

Table 13. FWOP Performance

Reach	Expected AEP	LTEP 10 Years	LTEP 30 Years	LTEP 50 Years	CNP 2%	CNP 1%	CNP 0.2%
AW1	1.00	1.00	1.00	1.00	0.00	0.00	0.00

4.4. Existing Without-Project Condition

This section presents EAD for the existing WOP condition. Hydraulic modeling resulted in minor differences for project impervious area changes between existing and future conditions. As a result, existing and future EAD estimates are similar.

4.4.1. Existing WOP EAD

Table 14 presents existing WOP EAD estimates by reach and structure type. Total existing WOP EAD for structures and structure contents is approximately $63 million. Existing WOP EAD for structures and contents are approximately $6 million lower than the FWOP condition. Table 15 shows that vehicles, clean-up costs, and emergency costs result in EAD of $27 million. Total existing WOP EAD is approximately $90 million, compared to $100 million for the FWOP condition.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

4.5. Without-Project Equivalent Annual Damages

This section presents equivalent annual damages for the WOP condition. To obtain equivalent annual damages, expected annual damages are interpolated between existing and future years and discounted back to present value in HEC-FDA. As previously noted, existing WOP and FWOP EAD estimates are similar, and therefore equivalent annual damages are near FWOP EAD estimates. Equivalent damages were calculated using the current federal discount rate of 2.5 percent.

Table 17 and Table 18 display equivalent annual damage estimates for structures and contents, and other damage categories. Equivalent annual damages for structures and contents are nearly $66 million. Auto, clean-up, and emergency cost equivalent annual damages exceed $28 million. Total WOP equivalent annual damages exceed $94 million.

Table 17. WOP Equivalent Annual Damages 2.5% (Structures and Contents)

Reach	Residential	Commercial	Industrial	Public	Total
AW1	$16,001	$8,699	$109	$165	$24,974

5. Other Social Effects WOP Condition

Engineering Regulation 1105-2-100 Appendix D identifies categories that directly relate to the quality of individuals' lives and their communities that may be included in the OSE account, specifically: urban and community impacts; life, health, and safety factors; displacement; long-term productivity; and energy requirements and energy conservation. Selected categories that are relevant to decision making should be reported for each alternative plan.

5.1. Life Safety Analysis

Life loss qualifies as an Other Social Effects (OSE) category. A life safety analysis includes the estimation of the population at risk and associated statistical parameters for life loss. For this analysis, life loss was calculated using LifeSim 2.0.5 for the future without project (FWOP) condition and future with project (FWP) condition for the final array of alternatives. This software uses Monte Carlo simulation to estimate the number of individuals at risk of life loss by probabilistic event for nighttime and daytime populations. Life loss was calculated for each

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

frequency event used in the HEC-FDA model. The hydraulic results of the FWOP and FWP conditions were compared to estimate residual life loss after the project is implemented and to assess life safety risk during flood events at various flood frequencies. Inputs, assumptions, modeling results, and average annual life loss calculations are detailed in subsequent sections.

5.1.1. Data Sources and Input Parameters

5.1.1.1. Structure Inventory

The structure inventory was developed from the USACE National Structure Inventory (NSI) 2022 data. The inventory was developed using building footprints, parcel data, CoreLogic data, FEMA Hazards US (HAZUS) data, and census data. The inventory was calibrated in high-risk areas using aerial imagery and flood inundation maps. Population values are representative of 2020 estimates and are based on 2010 census block data and 2020 county data.

Structure placement and structure attributes in the LifeSim models will not exactly match the structure placement and structure attributes used in the HEC-FDA modeling. The number of structures inundated by event and by alternative will vary between the HEC-FDA model and the LifeSim model. NSI 2022 was utilized due to the quality of the population data, which is one of the key elements of the life safety analysis.

5.1.1.2. LifeSim Uncertainty Parameters

The LifeSim software follows a warning and response timeline of events beginning with the identification of the hazard (e.g., overbank flow starts) and ending with the public taking protective action (also known as mobilization). The warning and response timeline in LifeSim follows events that would occur during a flooding emergency. The timeline is shown below in Figure 15; the real-world actions are shown in blue, and the corresponding LifeSim model parameters are shown below in white.

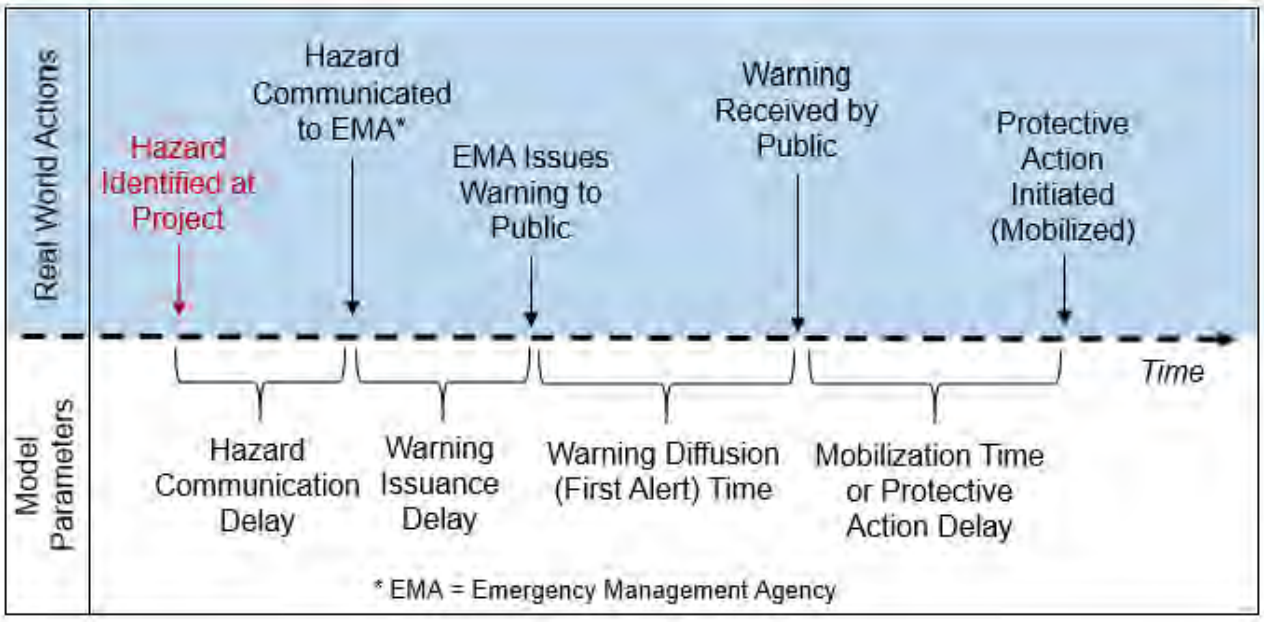

Figure 15. LifeSim Warning and Response Timeline

The definitions of the LifeSim uncertainty parameters are below:

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

- Imminent Hazard Identification Time: The time at which a potential hazard is about to occur or is actively occurring and local emergency officials should be alerted so they can begin the warning and evacuation process. This parameter is often referred to as the "warning time".
- Hazard Communication Delay: The time it takes to contact local emergency officials to alert them of the hazard.
- Warning Issuance Delay: The time it takes the local emergency officials to issue a warning/evacuation order, which includes the time it takes to craft a warning message and/or get approval from other authorities to send out the warning message to the public.
- Warning Diffusion Time: The time it takes to disseminate a warning to the public using various communication channels (e.g., reverse 911, route alerting, social media).
- Protective Action Initiation Delay: The time it takes the public to evacuate once they have received a warning.

The study area was divided into four Emergency Planning Zones (EPZ's) due to the unique hydraulic characteristics and hydrologic timing of each area. Each area either floods from a different source or begins flooding at a different time than the other areas. All EPZ's are assigned the same warning duration relative to when flooding begins in that respective area. The Imminent Hazard Identification Times (i.e., warning times) for each EPZ's 2-4 were set relative to the hazard occurrence time of EPZ 1. The EPZ's are shown in Figure 16 below.

The Imminent Hazard Identification Times were determined through discussion with the hydrologic engineer. All AEP events are characteristic of flash flooding, and it is anticipated that there would be minimal forecasting or warning to the population to evacuate. The warning times reflect the flashy nature of the system. Warning times were extended for the lower frequency events starting at the 1% AEP event since these events would be forecasted further in advance than the higher frequency events. The warning times are displayed in Table 19.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

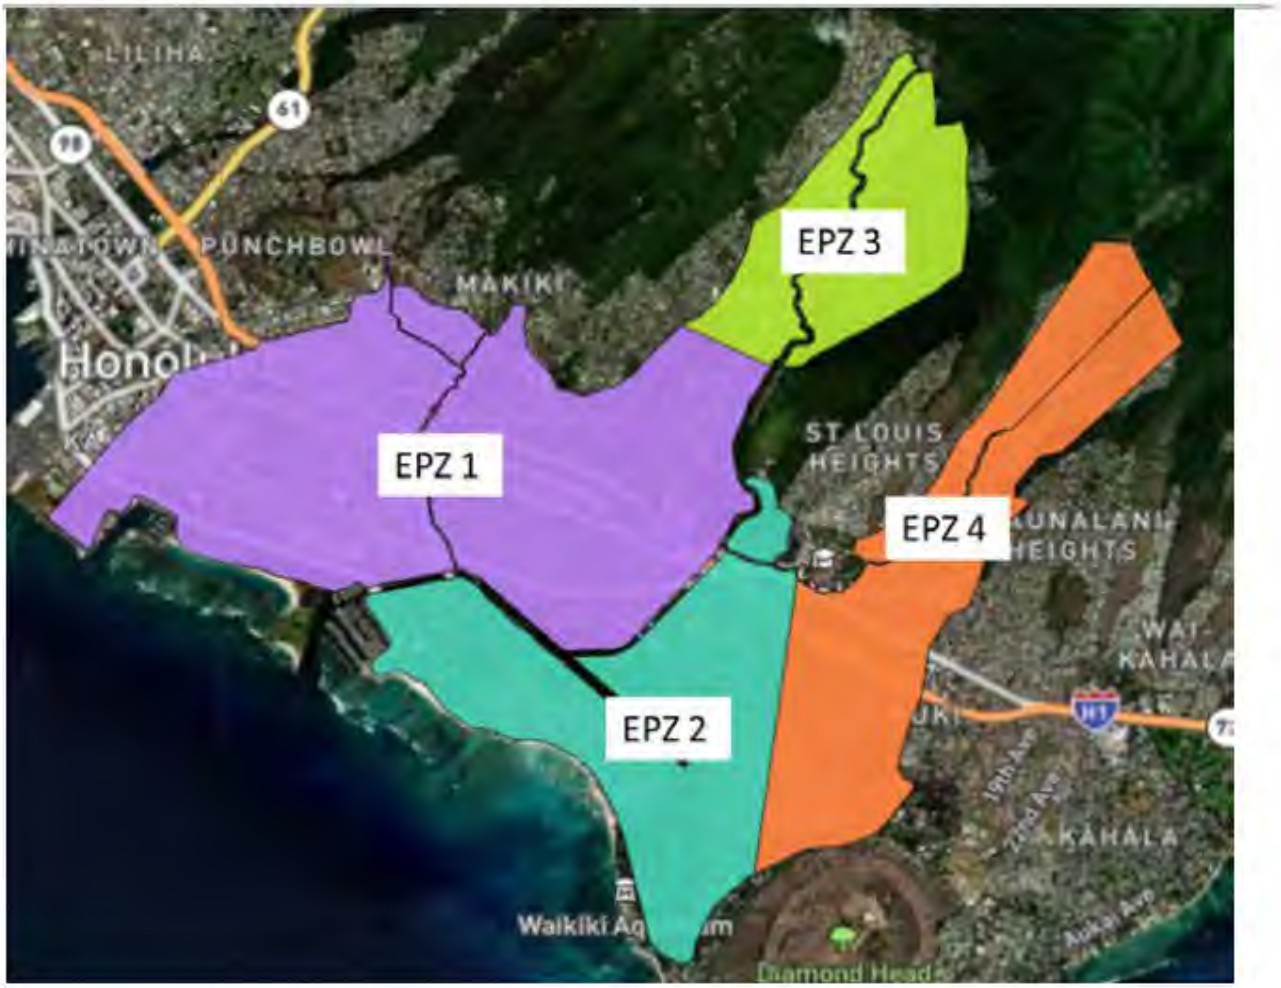

Figure 16. LifeSim Emergency Planning Zones

Table 19. Relative Warning Times, Uniform Distribution

Event	Min Warning Time (Hours)	Max Warning Time (Hours)
0.2% AEP	-4	0
0.5% AEP	-4	0
1% AEP	-4	0
2% AEP	-4	0
5% AEP	-2	0
10% AEP	-2	0
20% AEP	-2	0
50% AEP	-2	0

The uncertainty parameters in LifeSim, including Warning Issuance Delay, the Warning Diffusion curves, and the Protective Action Initiation (PAI) curve, utilize the preset Unknown curves. The Hazard Communication Delay was set to a uniform distribution of 0.01 to 0.5 hours. This LifeSim modeling method follows the MMC-MCX FY23 Standard Operating Procedures for consequence modeling, which is appropriate to use when there is limited information available

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

regarding local emergency action planning and risk awareness. These curves allow for significant uncertainty regarding how quickly a warning would be disseminated to the public and what percentage of the public would take protective action. For each event, 1,000 Monte Carlo iterations were simulated. The LifeSim curves used in the Ala Wai model are displayed below.

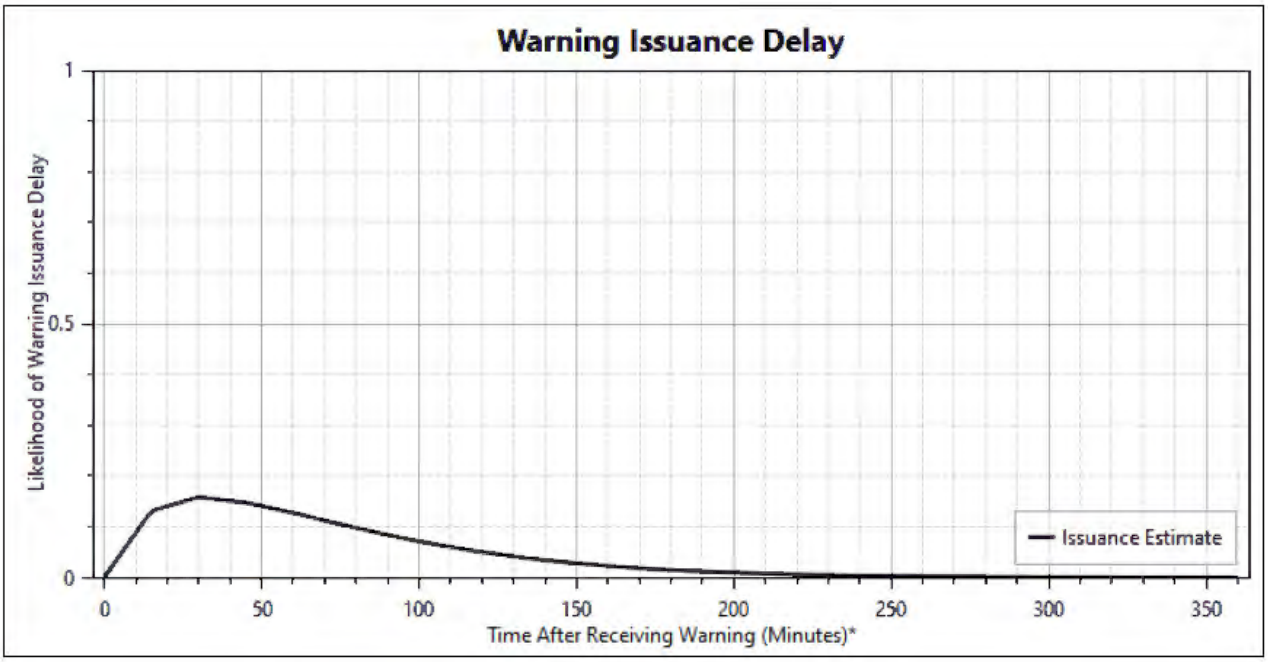

Figure 17. Unknown Warning Issuance Delay Curve

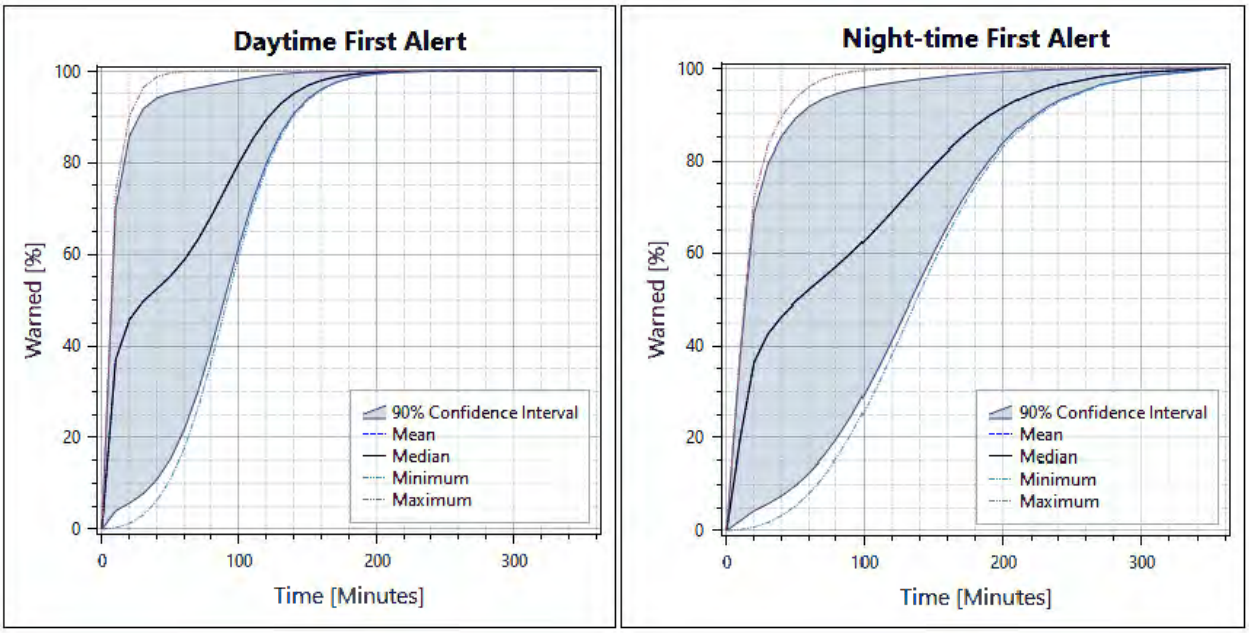

Figure 18. Unknown Warning Diffusion Curve

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

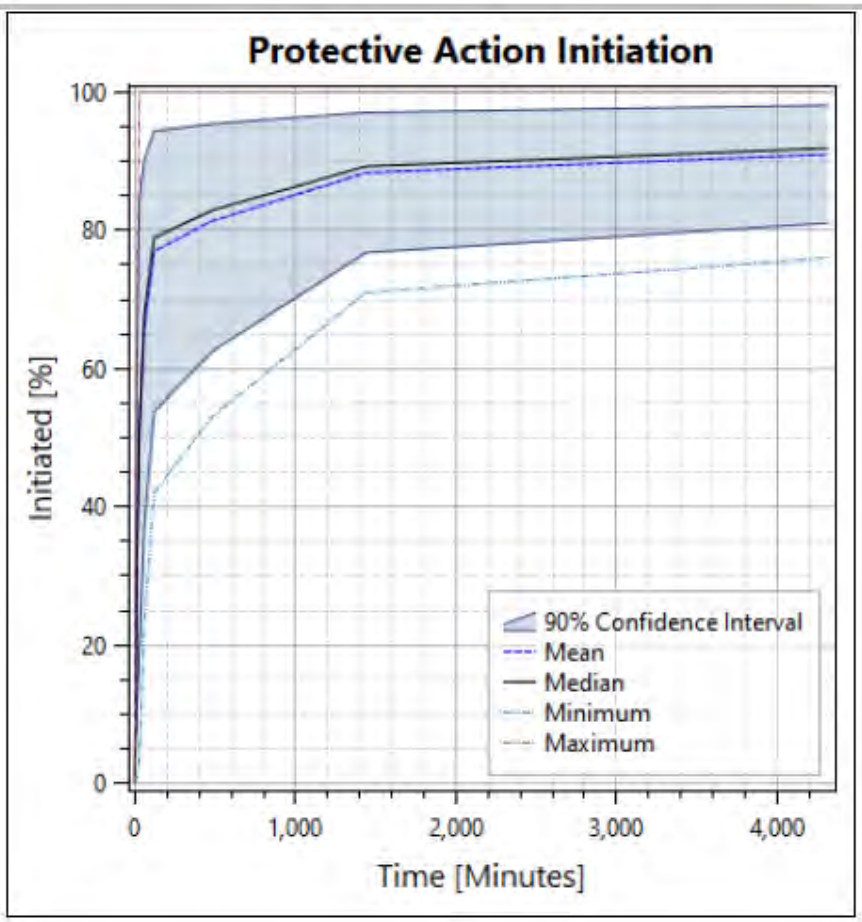

Figure 19. Unknown/Perception: Unknown warning PAI Curve

5.1.2. Ala Wai Life Safety Risk

The three major streams modeled in the Ala Wai watershed are the Makiki, Manoa, and Palolo streams. The Manoa and Palolo streams join to form the Manoa-Palolo Canal. The Manoa-Palolo Canal, Makiki Stream, and three low-lying drainage areas empty into the Ala Wai Canal. The HEC-RAS modeling utilized unsteady flow with 1D modeling in the stream channels and 2D modeling in the overbank extents. This allows for depths, velocities, and arrival times to be generated and imported into the LifeSim software. The modeling extent covers major streams and tributaries of the watershed.

The Ala Wai LifeSim model includes FWOP hydraulic conditions and FWP hydraulic conditions for Alternatives 1, 2B, and 5.3. The neighborhoods who experience life loss under the FWOP condition are shown in Figure 20.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Figure 20. Communities with Expected Life Loss

5.1.2.1. FWOP Life Safety Risk

Table 20 shows the FWOP life safety results for Ala Wai, including the the number of structures inundated, PAR, average life loss, average depth on structures, and average velocity on structures. As shown in Table 2, each event inundates several structures, and depths and velocities are significant enough to cause fatalities on average starting at the 5% AEP event. The 0.2% AEP event results in the highest flood depths, which causes daytime and nighttime average life loss to increase to 6 and 5, respectively.

Communities expected to experience life loss include Waikiki, Ala Moana, Kakaako, Pawaa, Makiki, McCully-Moiliili, Manoa, Palolo, and Kapahulu. Both the University of Hawaii at Manoa and Hokulani Elementary School sampled life loss. The maximum depth and velocity at the university are 14.5 ft and 0.9 ft/s. The maximum depth and velocity at the elementary school are 5.2 ft and 1.1 ft/s. The maximum depth and velocity of all inundated structures are 14.6 ft and 16.2 ft/s.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Both Waikiki and McCully-Moiliili experience much of the life loss, and McCully-Moiliili has been identified as a low-income area. The average depth and velocity of structures with life loss in Waikiki are 2.3 ft and 0.5 ft/s. The average depth and velocity of structures with life loss in McCully-Moiliili are 3.0 ft and 0.8 ft/s. The average depth and velocity of structures with life loss around the elementary school are 6.8 ft and 4.0 ft/s.

Table 20. Ala Wai FWOP Life Safety Risk by AEP Event

Hydraulic Scenario	Structures Inundated	Population at Risk		Average Life Loss		Max Life Loss		Average Depth (ft)	Average Velocity (ft/s)
		Day	Night	Day	Night	Day	Night		
0.2% AEP (500yr)	5,518	62,268	58,149	6	5	23	19	2.02	1.34
0.5% AEP (200yr)	5,060	58,026	54,109	3	3	15	19	1.75	1.23
1% AEP (100yr)	4,640	51,576	50,149	2	1	10	11	1.49	1.15
2% AEP (50yr)	4,065	44,333	44,939	1	1	7	5	1.27	1.03
5% AEP (20yr)	2,910	29,475	31,359	1	1	5	5	0.97	0.89
10% AEP (10yr)	1,691	15,810	17,509	0	0	4	5	0.81	0.84
20% AEP (5yr)	760	7,088	6,927	0	0	5	3	0.74	0.89
50% AEP (2yr)	121	790	1,050	0	0	0	3	0.44	0.37

Figure 21 shows the average nighttime life loss for the 0.2% AEP event. The heat map indicates whether life loss occurred during any of the 1,000 sample iterations. Green portions of the heat map indicate that life loss occurred in that area for a few iterations. Yellow, orange, or red portions of the heat map indicate that life loss occurred in that area for several iterations.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

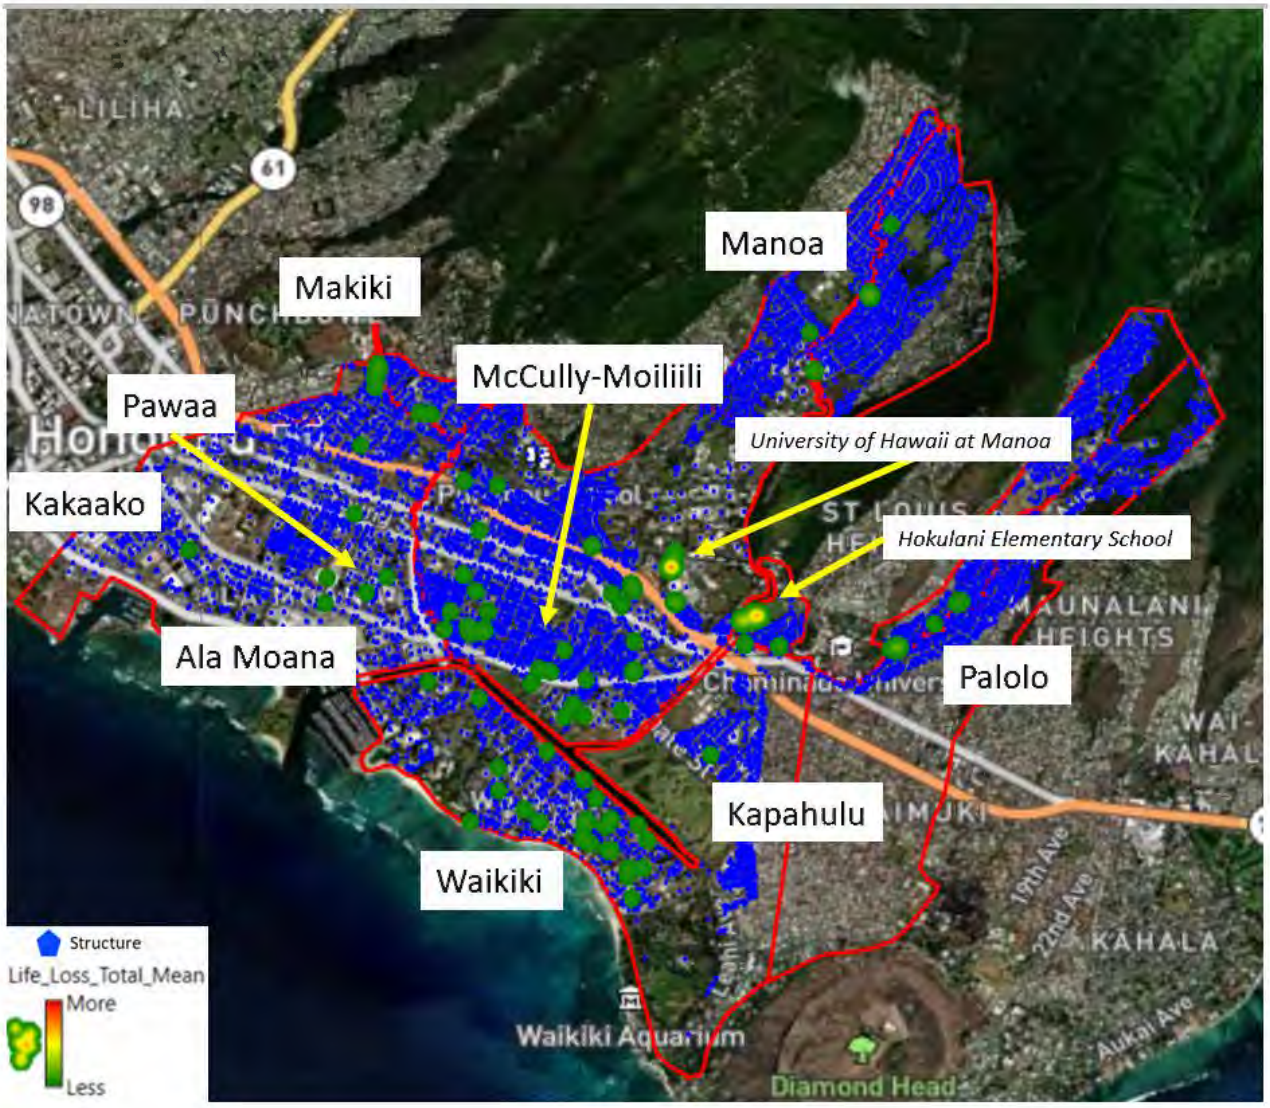

Figure 21. FWOP 0.2% AEP Average Night Life Loss Heat Map

5.1.2.2. FWOP Expected Annual Life Loss

The Risk Management Center (RMC) TotalRisk 1.0 software was used to estimate Expected Annual Life Loss (EALL) from the LifeSim outputs. RMC-TotalRisk 1.0 considers the full range of life loss uncertainty results from LifeSim, including daytime and nighttime results, and uses Monte Carlo simulation to calculate the average of all sampled distributions. The EALL calculations do not include hydrologic and hydraulic uncertainty like damage estimates do.

Table 21 shows that EALL for the FWOP condition is 0.09. Under the without project condition, life loss occurs only at very low frequency events, and average annual life loss is near zero.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Table 21. FWOP EALL

Scenario	Expected Annual Life Loss
FWOP	0.0491

5.2. Tourism and Recreation

The study area includes Ala Moana and Waikiki beaches which are frequented by residents and tourists and provide land access to some of the most famous surf breaks on Oahu. Beach and ocean related recreation is a central part of the community and is the primary reason visitors frequent the island. Beaches provide recreational, cultural, and commercial value to the economy, and provide the local ecosystem with vital habitats. Recreational activities include walking, running, swimming, bird watching, whale watching, surfing, diving, snorkeling, kayaking, windsurfing, and canoeing. Beaches in the study area are freely accessible to the public, and visitor spending provides significant economic value to Honolulu and the State of Hawaii. Table 21 shows visitor count and expenditures for 2019, prior to COVID-19 mandates being adopted, and for 2021, the latest year full data is available (note major COVID-19 mandates that restricted travel were still in place in 2021).

Tourism data from prior to and during the COVID-19 pandemic shows that an external shock causing decreased tourism would result in less spending in the region, which would negatively impact the local economy. In 2019, the number of yearly visitors to Oahu by air was 6.2 million. In 2020 with COVID-19 mandates in place, this number decreased to 1.5 million, and visitors from U.S. markets spent approximately $1,400 per person per trip in 2020 dollars. Domestic tourism spending decreased from about $8 billion in 2019 to $2 billion in 2020 as a result of the COVID-19 pandemic. Per visitor per trip spending for U.S. market air travelers for Oahu as of November 2022 was $1,800. The significant economic impact of decreased tourism during 2020 due to the COVID-19 pandemic provides insight into the economic impacts of potential decreased tourism if significant flooding were to occur near Ala Moana and Waikiki.

Table 22. Tourism Data for the Island of Oahu (Honolulu County)

Category	2021 YTD	2019 YTD	Percent Change
Total Expenditures (Millions of $)	$5,660	$8,140	-30.5
Visitor Arrivals (Air)	3,330,948	6,154,248	-45.9
Average Daily Census	73,923	114,596	-35.5

Source: Hawai'i Department of Business, Economic Development & Tourism

Figure 15 shows how disruptions to tourism, caused by the COVID-19 pandemic, resulted in high unemployment in urban Honolulu. In March 2020, there was a clear drop in employment of roughly 100,000 individuals in the area, which corresponded with travel restrictions for tourists taking effect. The number of individuals employed in the leisure and hospitality industry decreased from 76,000 to 38,000 from February 2020 to April 2020 in urban Honolulu. During this same time period, the number of unemployed individuals increased from 9,000 to 82,000.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Over half of the number of unemployed individuals in urban Honolulu during the initial COVID-19 mandates came from the leisure and hospitality industry. This data shows that tourism and recreation account for a major portion of economic activity in the study area, and that tourism-driven economic activity is sensitive to external shocks.

In the absence of a federal project, inundation in the study area, particularly near access points to beaches, harbors, and the hotel zone of Waikiki, could negatively impact tourism and local recreation. If a future storm event were to have a major negative impact on tourism, the impact on the local economy would be significant.

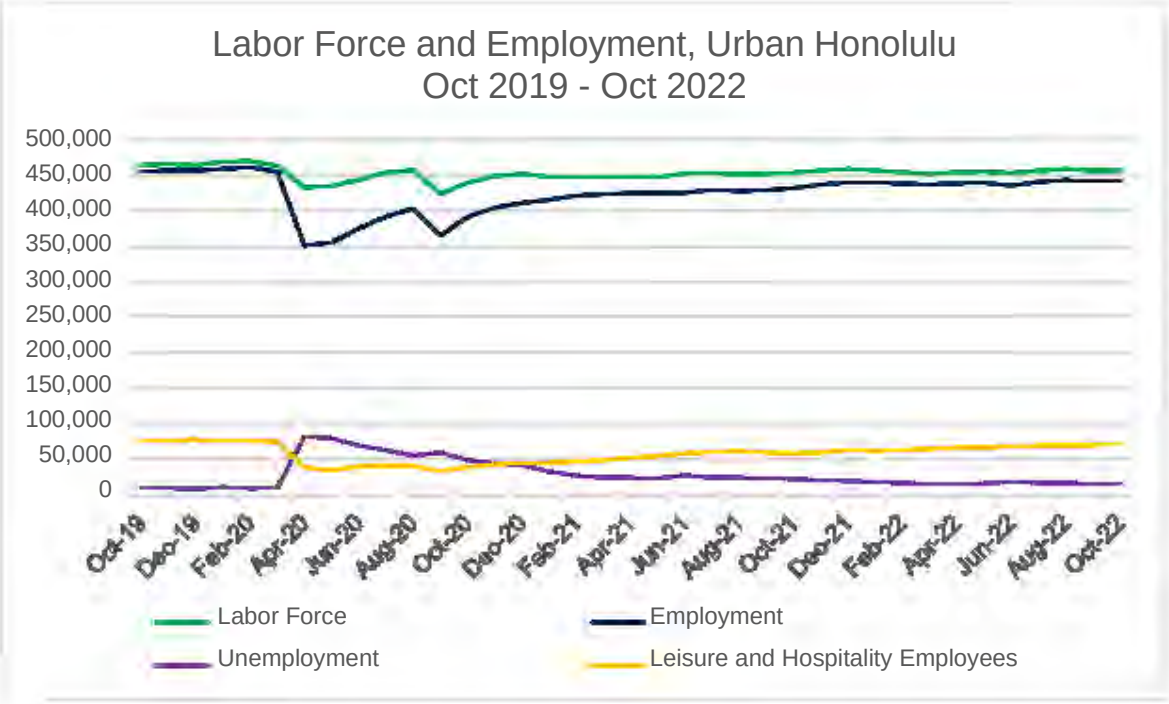

Figure 22. Labor Force and Employment

Source: data.bls.gov/timeseries

5.3. Social Vulnerability

Socially vulnerable populations have characteristics which may result in their being impacted more negatively than other populations, or the population on average. The presence of socially vulnerable populations was evaluated during the formulation of alternative plans using census data and the CDC's Social Vulnerability Index presented in Figure 8 of Section 2.2. Social Vulnerability Index scores are highest in portions of reaches AW2R, AW3L, AW3R, and AW9R and lowest in reaches AW8L and AW8R. Apart from reaches AW8R and AW8L, all reaches in the study area contain some census tracts with moderate to high social vulnerability scores, including scores ranging from 0.5 to above 0.8. In the absence of a federal project, these socially vulnerable communities will continue to be susceptible to flood risk.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

6. With-Project Alternatives Analysis

6.1. With-Project Analysis Overview

To evaluate each alternative plan, alternatives were modeled in HEC-FDA for each plan and year. Equivalent annual damages for the WOP condition were compared to the with-project equivalent annual damages for each alternative to estimate damages reduced, or benefits of each alternative plan. Alternatives were modeled for three structural plans in FDA and comprise the final array of alternatives: Alternative 1, Alternative 2b, and Alternative 5.3.

Separately, a nonstructural only plan was evaluated using FWOP FDA outputs and a nonstructural workbook developed by USACE Omaha District. The result for the nonstructural only plan resulted in lower net benefits than the structural alternatives and was eliminated from the final array. Following the TSP milestone, the PDT analyzed whether combining nonstructural measures in some reaches with the structural TSP plan would be feasible. It was determined that nonstructural measures would only be feasible in reaches that also benefited from the structural plan, and the structural plan had higher overall net benefits. Reaches not benefitting from the structural plan include reaches AW5, AW8L, AW8R, and AW9L. These reaches had nonviable BCRs for nonstructural measures. Notably, these reaches had much lower FWOP damages than other reaches in the study area.

6.2. Description of the Final Array of Alternatives

This section describes the final array of alternatives, which includes three structural alternatives that were modeled in HEC-FDA. These alternatives were compared to the WOP condition, or the no-action plan in order to estimate benefits. Under the no-action plan, structures would be subject to flood risk, resulting in economic damages as outlined in Section 4.

6.2.1. Alternative 1

Alternative 1 was formulated to maximize flood storage throughout the basin and includes the following measures: Kanaha floodwall and Maikiki Park detention basin, Manoa Park detention basin, Woodlawn Drive floodwall, Koaki Road floodwall, Kaimuki High School floodwall, and the Ala Wai Golf Course detention basin.

The Kanaha floodwall would be placed along Kanaha Ditch and measure 6 feet in height along the right bank. The Maikiki Park detention basin would measures 450 feet by 250 feet and provide approximately 21.6 ac-ft of storage. The Manoa Park detention basin would be 700 feet by 600 feet and provide approximately 54.1 ac-ft of storage. The Woodlawn Drive floodwall would be constructed along the right bank of the Manoa Stream and would be approximately 6 feet in height. This floodwall protects the area west and south of the Manoa Stream at Woodland Drive and prevents overland flooding that moves south to the University of Hawaii. The Koali Road floodwall would be constructed along the left bank of the Manoa Stream to contain floodwaters that leave the channel at the Kanewai Community Park and along Koali Road. The floodwall would be a maximum height of 6 feet. The Koali Road floodwall is necessary to mitigate for increased discharge from the Woodlawn Drive floodwall. The Kaimuki High School floodwall would be approximately 5 ft in height and prevent inundation in residential areas east of Kaimuki High School. The Alai Wai Golf Course Detention area would place an inline structure on the Palolo Stream that includes five culverts that pass normal flows and divert high flows to the golf course detention area, with berms surrounding the golf course on the north

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

and east perimeters. Detailed specifications for these measures are included in the H&H Appendix.

6.2.2. Alternative 2b

Alternative 2b was designed to maximize conveyance of floodwaters through the main channels in the watershed. This alternative includes the Kanaha floodwall and Makiki District Park detention basin, Woodlawn Drive floodwall, Koali Road floodwall, Kaimuki High School floodwall and Ala Wai Canal floodwall.

The Ala Wai Canal floodwall extends on the left bank from the most upstream end of the Ala Wai Canal back to the mouth of the canal. The right bank of the floodwall extends from the right bank of the Manoa-Palolo Canal near Lunalilo Parkway to the confluence with the Ala Wai Canal and continues along the right bank of the Ala Wai Canal to the mouth of the canal. Detailed specifications for this measure are included in the H&H Appendix.

6.2.3. Alternative 5.3

Alternative 5.3 is a more detailed version of Alternative 5, which was presented at the TSP Meeting and initially included the Kanaha floodwall and Makiki District Park detention area, Manoa District Park detention area, Woodlawn Drive floodwall, Koali Road floodwall, Ala Wai Canal Floodwall with Kaimuki High School Floodwall and Ala Wai Golf Course detention area. After initial modeling in RAS and FDA showed induced water surface elevations and damages from the Makiki and Manoa detention areas, and the Kanaha floodwall wasn't economically justified, the Makiki District Park detention area, Kanaha floodwall, and Manoa District Park detention area were removed from the alternative and the alternative was re-modeled in RAS and FDA prior to the selection of the Alternative as the TSP. Note that the Kanaha floodwall and Makiki detention area needed to be justified by using only damages from downstream of the river station that met the 800 cfs discharge requirement, which means that damages in 3R and 3L were excluded when evaluating whether to retain these measures. Alternative 5.3 was achieved by refining floodwall alignments and increasing the berm height around the Ala Wai Golf Course detention area. Several iterations of this alternative were modeled between the selection of the TSP and the release of the Draft Report to optimize project performance, including floodwalls along Makiki between Reaches 2R and 2L, and several different levee heights. Ultimately, Alternative 5.3 represents the version which optimized project performance.

6.3. With-Project Annual Damages and Benefit Summaries

This section displays the with-project damages and benefits for the final array of alternatives. Residual damages that occur with each alternative plan in place are also displayed in this section.

6.3.1. Alternative 1 With-Project EAD

Expected annual damages for the WP and FWP conditions are the basis for calculating equivalent annual damages and benefits. With-project EAD are presented in this section.

Table 23 and Table 24 display WP EAD for Alternative 1 under existing conditions. Damages to structures and contents are approximately $46 million, while damages from vehicles, clean-up costs, and emergency costs are approximately $21 million.

6.3.2. Alternative 1 Equivalent Annual Benefits

Equivalent annual benefits are calculated as the difference between equivalent annual WOP and WP damages for each alternative. Since EAD for existing and future conditions are similar, equivalent annual with-project damages are similar to EAD estimates. Table 27 displays equivalent annual benefits for Alternative 1 by reach. Implementing this alternative results in equivalent annual benefits of nearly $27 million. Reach AW1 experiences the largest reduction in damages, while nearly $4 million of damages are induced in reach AW4.

Table 27. Alternative 1 Equivalent Annual Benefits 2.5%

Reach	Structure and Contents	Other Damages	Total
AW1	$10,330	$5,503	$15,833
AW2L	-$282	-$86	-$368
AW2R	-$79	$158	$79
AW3L	$161	$29	$191
AW3R	$2,991	$1,360	$4,351
AW4	-$2,449	-$1,255	-$3,704
AW5	$0	$1	$1
AW6	$515	$168	$684
AW7L	$929	$275	$1,204
AW7R	$7,335	$1,304	$8,639
AW8L	-$68	-$14	-$81

6.3.3. Alternative 2b With-Project EAD

Table 28 and Table 29 display WP EAD for Alternative 2b under the existing condition, which is approximately $37 million for structures and contents and $14 million for other damages. Total WP EAD is just over $50 million.

Table 28. Alternative 2b WP EAD Existing Condition (Structures and Contents)

Reach	Residential	Commercial	Industrial	Public	Total
AW1	$757	$545	$7	$17	$1,327

6.3.4. Alternative 2b Equivalent Annual Benefits

Equivalent annual damages for Alternative 2b are nearly the same as WP EAD since there is very little difference in existing and future condition EAD. Equivalent annual damages for Alternative 2b are subtracted from WOP damages to obtain equivalent annual benefits, which are shown in Table 32. Equivalent annual benefits for Alternative 2b are approximately $43 million. This alternative results in induced damages of over $11 million in reach AW2R.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Table 32. Alternative 2b Equivalent Annual Benefits 2.5%

Reach	Structure and Contents	Other Damages	Total

Total	**$35,462**	**$16,843**	**$52,303**

Note: values in $000s; FY23 price levels

6.3.7. Residual Equivalent Annual Damages

The following tables present residual equivalent annual damages, or the damages that are expected to occur with the project in place, for each alternative in the final array.

Table 38 shows that equivalent annual damages with Alternative 1 in place are approximately $67 million. Equivalent annual damages with Alternative 2b in place are presented in Table 39, and are approximately $50 million. Table 40 displays equivalent annual damages with Alternative 5.3 in place, which are approximately $42 million.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

6.4. Other Social Effects With-Project Condition

This section summarizes the OSE categories for the final array of alternatives, which include life safety risk, tourism and recreation, and social vulnerability.

6.4.1. Life Safety

6.4.1.1. Alternative 1 Life Safety Risk

Table 41 summarizes LifeSim results for Alternative 1. Structures are inundated at each AEP event, but depths and velocities are not significant enough to cause fatalities until the 1% AEP event. The least frequent event results in the highest flood depths, which causes both daytime and nighttime average life loss to increase.

Like the FWOP, communities that experience life loss with Alternative 1 in place include Waikiki, Ala Moana, Pawaa, Makiki, McCully-Moiliili, Manoa, Palolo, and Kapahulu. Life loss is still sampled at Hokulani Elementary School, but the maximum depth and velocity is 3.0 ft and 0.5 ft/s (compared to 5.2 ft and 1.1 ft/s for the FWOP). Maximum depth and velocity of all inundated structures is 12.6 ft and 17.3 ft/s.

Waikiki, McCully-Moiliili, and Hokulani Elementary School experience a large portion of WP life loss. The average depth and velocity of structures with life loss in Waikiki are 2.4 ft and 0.5 ft/s. The average depth and velocity of structures with life loss in McCully-Moiliili is 4.1 ft and 0.9 ft/s. The average depth and velocity of structures with life loss around the elementary school is 5.0 ft and 0.9 ft/s.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

With Alternative 1 in place, life loss is reduced slightly. Alternative 1 inundates fewer structures than the FWOP condition for all events except the 50% AEP and the 20% AEP events. Life loss is not present until the 1% AEP event, instead of the 5% AEP event for the FWOP condition.

Table 41. Alternative 1 Life Safety Risk by AEP Event

Hydraulic Scenario	Structures Inundated	Population at Risk		Average Life Loss		Max Life Loss		Average Depth (ft)	Average Velocity (ft/s)
		Day	Night	Day	Night	Day	Night		
0.2% AEP (500yr)	5,422	61,688	59,541	4	4	19	21	2.25	1.29
0.5% AEP (200yr)	4,930	55,795	54,133	1	1	11	7	1.87	1.18
1% AEP (100yr)	4,305	48,996	48,750	0	1	6	7	1.59	1.10
2% AEP (50yr)	3,265	34,015	36,443	0	0	3	4	1.30	1.07
5% AEP (20yr)	2,156	17,290	22,042	0	0	3	3	1.04	0.98
10% AEP (10yr)	1,446	10,653	13,878	0	0	3	3	0.85	0.90
20% AEP (5yr)	778	5,655	5,730	0	0	3	3	0.72	0.87
50% AEP (2yr)	205	3,348	1,900	0	0	1	1	0.47	0.50

Figure 23 shows the average nighttime life loss for Alternative 1 for the 0.2% AEP event. The heat map indicates whether life loss occurred within these areas during any of the 1,000 sample iterations. Green portions of the heat map indicate life loss occurred in that area for a few

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

iterations and yellow, orange, or red portions of the heat map indicate life loss occurred for several iterations.

Figure 23. Alternative 1 0.2% AEP Event Average Night Life Loss Heat Map

6.4.1.2. Alternative 2b Life Safety Risk

Table 42 displays the LifeSim results for Alternative 2b. While structures are inundated at each event, depths and velocities are not significant enough to cause fatalities until the 0.5% AEP event. For the same event, daytime and nighttime average life loss is one.

Like the FWOP condition, life loss was sampled for the communities of Waikiki, Ala Moana, Kakaako, Pawaa, Makiki, McCully-Moiliili, Manoa, Palolo, and Kapahulu. Life loss is sampled at Hokulani Elementary School, where the maximum depth and velocity is 3.2 ft and 0.4 ft/s (compared to 5.2 ft and 1.1 ft/s for the FWOP). Maximum depth and velocity of all inundated structures is 10.9 ft and 17.3 ft/s.

Similar to the FWOP condition and Alternative 1, Waikiki and McCully-Moiliili experience life loss under Alternative 2b. The Pawaa-Ala Moana-Kakaako area and the area near Hokulani Elementary School also experience life loss. The average depth and velocity of structures with

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

life loss in Waikiki is 1.5 ft and 0.5 ft/s. The average depth and velocity of structures with life loss in the McCully-Moiliili area is 4.5 ft and 1.0 ft/s. The average depth and velocity of structures with life loss in the Pawaa-Ala Moana-Kakaako areas is 1.6 ft and 0.5 ft/s. The average depth and velocity of structures with life loss near the elementary school is 6.5 ft and 2.1 ft/s.

Average life loss is lower for Alternative 2b than for the FWOP condition, although Alternative 2b generally has slightly higher depths and velocities. Alternative 2b inundates fewer structures for all events, and average life loss is not sampled until the 0.5% AEP whereas it is sampled at the 5% AEP event for the FWOP condition.

Table 42. Alternative 2b Life Safety Risk by AEP Event

Hydraulic Scenario	Structures Inundated	Population at Risk		Average Life Loss		Max Life Loss		Average Depth (ft)	Average Velocity (ft/s)
		Day	Night	Day	Night	Day	Night

10% AEP (10yr)	744	4,693	6,063	0	0	3	3	0.85	1.09
20% AEP (5yr)	406	2,467	2,837	0	0	0	3	0.80	1.06
50% AEP (2yr)	81	360	617	0	0	0	0	0.60	0.57

Figure 24 shows the average nighttime life loss for Alternative 2b during the 0.2% AEP event. The heat map indicates whether life loss occurred during any of the 1,000 iterations. Green portions of the heat map indicate life loss occurred in that area for a few iterations and yellow, orange, or red portions of the heat map show life loss occurred in that area for several iterations.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

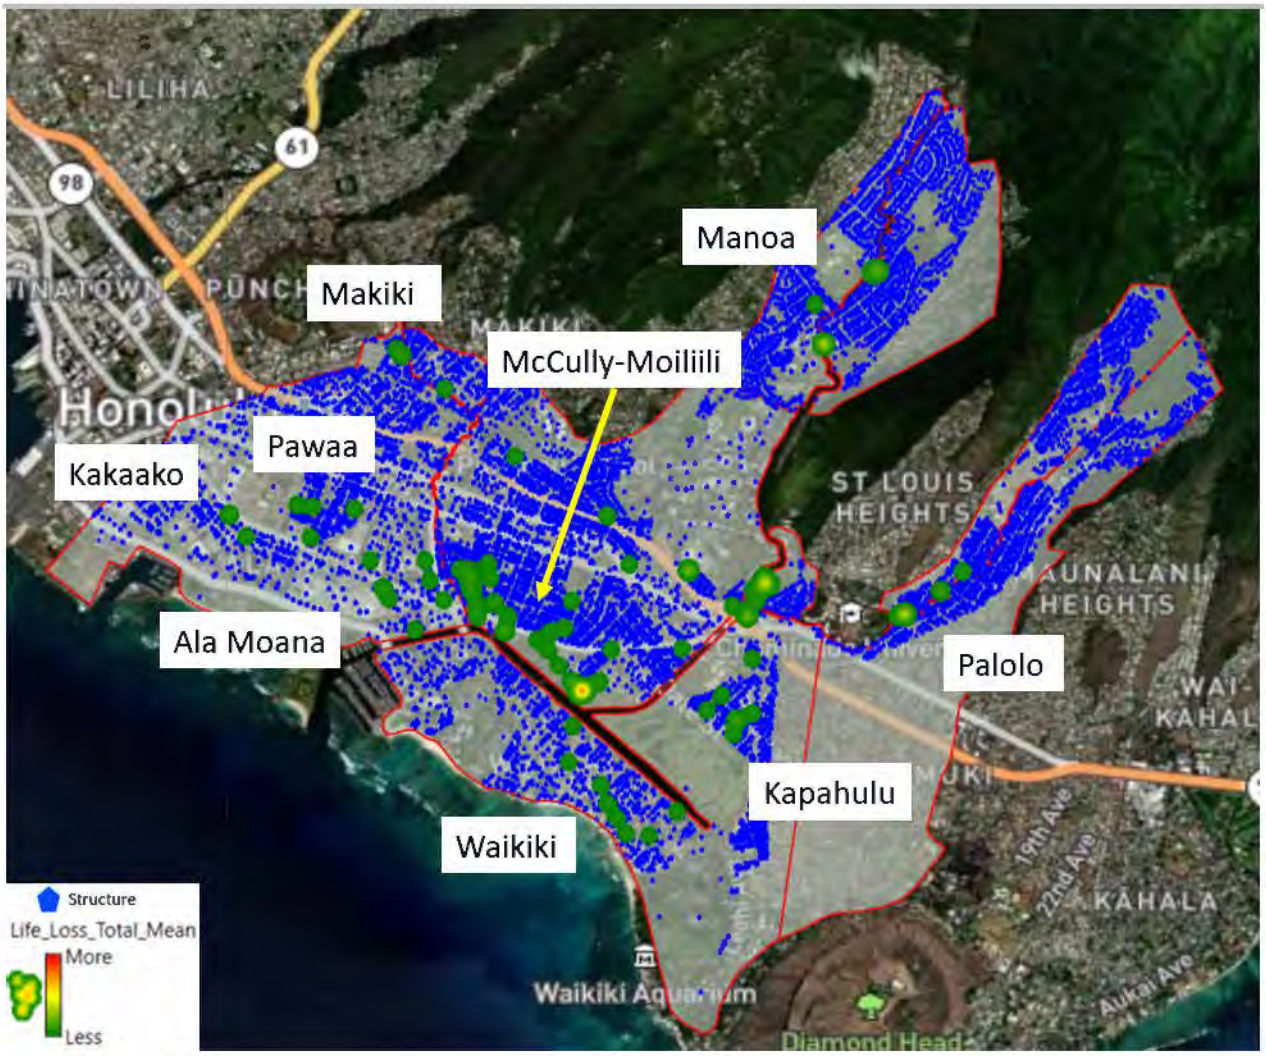

Figure 24. Alternative 2b 0.2% AEP Event Average Night Life Loss Heat Map

6.4.1.3. Alternative 5.3 Life Safety Risk

Table 43 shows the LifeSim results for Alternative 5.3. Several structures are inundated at each AEP event but on average, depths and velocities are not significant enough to cause fatalities until the 0.5% AEP event. The 0.2% AEP event results in the highest flood depths, which causes daytime and nighttime average life loss to increase to 3 and 3, respectively.

Like the FWOP condition, communities with life loss include Ala Moana, Pawaa, Makiki, McCully-Moiliili, Manoa, and Palolo. Significantly less life loss was sampled in Waikiki, and no life loss was sampled in Kakaako. Life loss was not sampled at Hokulani Elementary School; however, it was sampled in 2 structures near the school. The maximum depth and velocity at these structures is 7.5 ft and 2.2 ft/s. Maximum depth and velocity of all inundated structures is 14.6 ft and 16.2 ft/s.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

McCully-Moiliili experiences most of the life loss for Alternative 5.3. The average depth and velocity of structures with life loss in the McCully-Moiliili area is 3.9 ft and 0.8 ft/s. The average depth and velocity of structures with life loss near the elementary school is 7.5 ft and 1.4 ft/s.

Average life loss is lower in Alternative 5.3 than the FWOP condition, and Alternative 5.3 has slightly lower average depths for the 0.5%, 1%, 2%, 5%, 20%, and 50% AEP events. Average velocities are slightly higher than the FWOP condition, due to increased conveyance. Alternative 5.3 inundates fewer structures than the FWOP condition for all events, and average life loss is not sampled until the 0.5% AEP event.

Table 43. Alternative 5.3 Life Safety Risk by AEP Event

Hydraulic Scenario	Structures Inundated	Population at Risk		Average Life Loss		Max Life Loss		Average Depth (ft)	Average Velocity (ft/s)
		Day	Night	Day	Night	Day	Night		
0.2% AEP (500yr)	4,366	39,840	39,696	3	3	20	33	2.16	1.42
0.5% AEP (200yr)	3,633	31,927	31,330	1	1	7	9	1.63	1.34
1% AEP (100yr)	3,041	25,477	24,983	0	0	5	4	1.29	1.27
2% AEP (50yr)	2,392	20,684	18,801	0	0	4	4	1.09	1.19
5% AEP (20yr)	1,575	11,356	11,585	0	0	3	3	0.95	1.11
10% AEP (10yr)	1,047	5,567	7,952	0	0	3	2	0.83	1.03

50% AEP (2yr)	89	321	641	0	0	0	0	0.37	0.45

Figure 25 shows the average nighttime life loss for Alternative 2b during the 0.2% AEP event. The heat map indicates whether life loss occurred during any of the 1,000 iterations. Green portions of the heat map indicate life loss occurred in that area for a few iterations and yellow, orange, or red portions of the heat map show life loss occurred in that area for several iterations.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

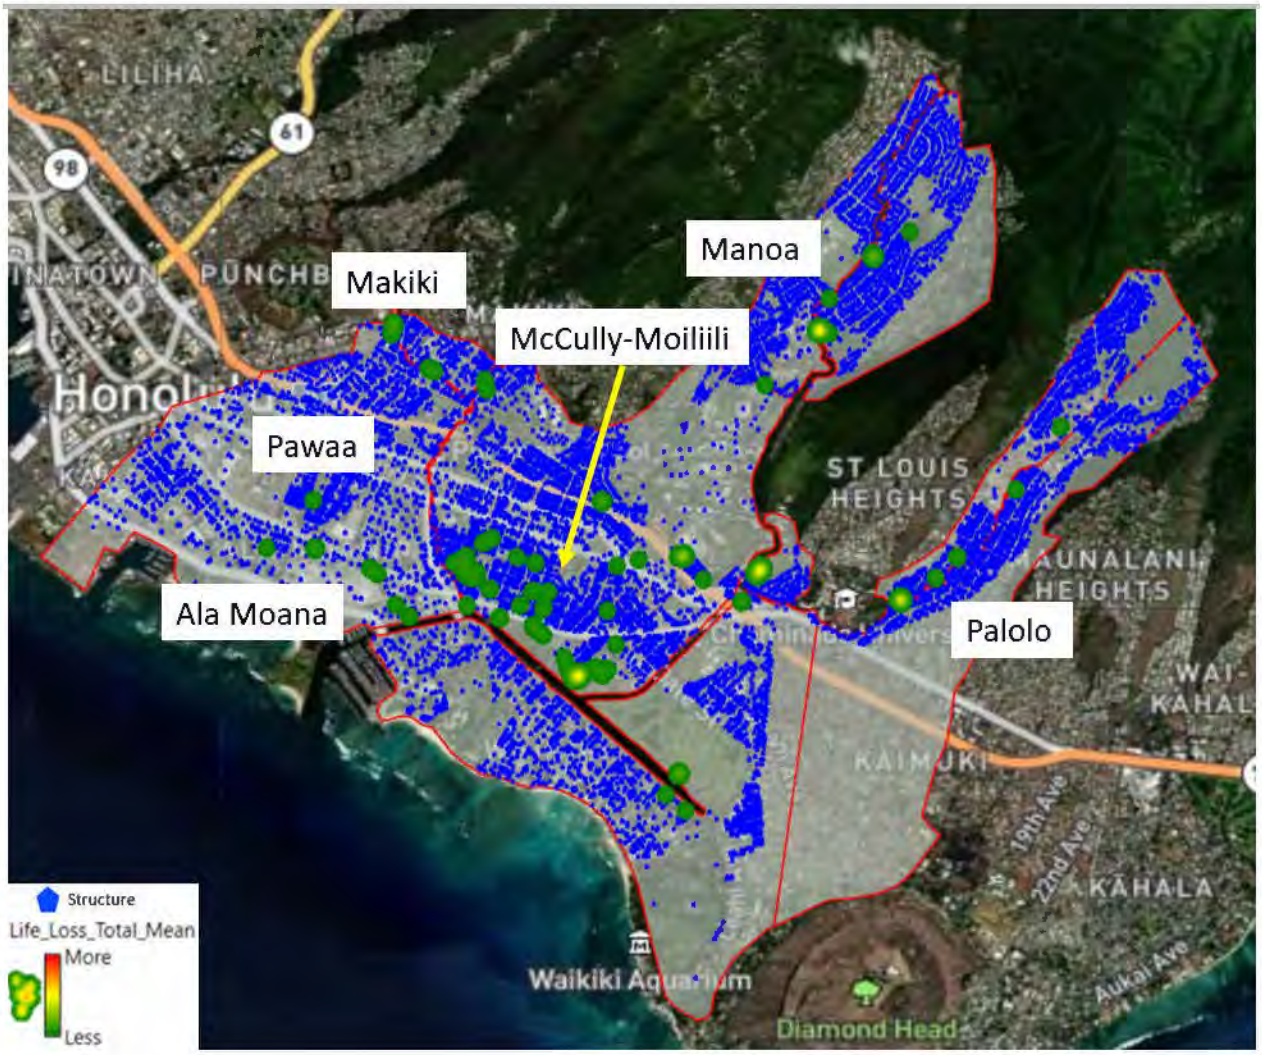

Figure 25. Alternative 5.3 0.2% AEP Average Daytime Life Loss Heat Map

6.4.1.4. Expected Annual Life Loss Estimates

For each alternative, the Risk Management Center (RMC)-TotalRisk 1.0 software, which utilizes Monte Carlo simulation, was used to estimate Expected Annual Life Loss (EALL). RMC-TotalRisk 1.0 considers the full range of life loss uncertainty results from LifeSim, including both daytime and nighttime results. The EALL computation in RMC-TotalRisk 1.0 is similar to the HEC-FDA computation of expected annual damages. The EALL calculation doesn't include hydrologic or hydraulic uncertainty.

Table 44 displays EALL estimates for the final array of alternatives. Alternative 1 and Alternative 5.3 slightly reduce EALL, while Alternative 2b induces EALL.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Table 44. Expected Annual Life Loss Estimates

Scenario	Expected Annual Life Loss	Expected Annual Life Loss Reduced
FWOP	0.0491	-
Alternative 1	0.0302	**0.0189**
Alternative 2b	0.0737	**-0.0246**
Alternative 5.3	0.0450	**0.0041**

6.4.2. Tourism and Recreation With-Project Condition

For all three alternatives, negative impacts to tourism and recreation caused by flooding under the WOP condition as presented in Section 5.2 would be reduced. Alternative 1 still has significant residual flooding for the 0.2% AEP event in reach AW1, which is the reach with the most hotels and beach access. Alternative 2b has less residual flooding in reach AW1 than Alternative 1. Alternative 5.3 has the least residual flooding for the 0.2% AEP event in reach AW1, and nearly eliminates equivalent annual damages in this reach. Alternative 5.3 also results in the highest reduction in flooding in reach AW2R. Of the Alternatives in the final array, Alternative 5.3 has the most positive impact on tourism and recreation, and would minimize disruptions to tourism and recreation and associated economic impacts detailed in Section 5.2.

6.4.3. Social Vulnerability With-Project Condition

Social Vulnerability Index scores are highest in portions of reaches AW2R, AW3L, AW3R, and AW9R. Apart from reaches AW8R and AW8L, all reaches in the study area contain some census tracts with moderate to high social vulnerability scores, including scores ranging from 0.5 to above 0.8. Alternative 5.3 results in the greatest reduction in damages in reaches AW2R and AW9R. Alternative 2b significantly induces damages in reach AW2R. Measures that reduced damages in AW3L and AW3R were removed from Alternative 5.3 because they induced damages and did not meet the 800 cfs requirement. Alternative 5.3 provides the greatest benefit to socially vulnerable census tracts in the study area.

6.5. Regional Economic Development

The RED account registers changes in the distribution of regional economic activity that results from each alternative plan. Evaluations of regional effects are carried out using nationally consistent projections of income, employment, output, and population.

To evaluate RED, the USACE Regional Economic System (RECONS) model was used. RECONS is a USACE-certified regional economic model designed to provide accurate and defensible estimates of regional economic impacts and contributions associated with USACE projects, programs, and infrastructure. Regional economic impacts and contributions are measured as economic output, jobs, income, and value added. Estimates are provided simultaneously for three levels of geographic impact area: local, state, and national. RECONS is an input/output (IO) model that uses IMPLAN data, which is comprehensive economic data gathered from government agencies and the private sector. Within RECONS, the Civil Works Spending Module was used to estimate local, state, and national impacts. For this study, the generic area used was Honolulu County, the business line selected was Flood Risk Management, and the work activity selected was Flood Risk Management Construction. Since RECONS is an IO model, construction dollars must be spent for an impact to occur. IO models

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

assume that there is a relationship between the volume of output of an industry and the volume of various inputs used to produce that output. The impact of construction dollars on the economy more broadly is based on the multiplier effect, or the proportional amount of increase in final income that results from project spending. Therefore, only WP conditions are analyzed. In the absence of the project, it is likely that RED would be negatively impacted by flood events.

The economic impacts presented below exclude IDC since this portion of project costs are not spent within the region. Purchases of land are similarly excluded since this cost is considered a transfer from one individual to another. Results are presented for each alternative in this section in FY23 price levels.

6.5.1. Alternative 1 RED

Table 43 displays RECONS output for Alternative 1. This alternative would result in nearly 1,400 full time jobs in the local economy, and in over 3,500 nationwide. Total labor income in the U.S. would be over $251 million, and value added would exceed $330 million.

Table 45. Alternative 1 Regional Economic Impact

Area	Jobs*	Labor Income	Value Added
Local			
Direct Impact	1,384	$116,355,133	$115,081,247
Secondary Impact	1,384	$43,994,713	$79,079,193
Total Impact	1,384	$160,349,846	$194,160,439
State			
Direct Impact	1,468	$116,619,304	$115,263,492
Secondary Impact	729	$44,773,262	$80,911,346
Total Impact	2,197	$161,392,565	$196,174,838
US			
Direct Impact	1,824	$135,729,196	$132,787,686
Secondary Impact	1,704	$115,518,850	$197,796,545
Total Impact	3,528	$251,248,046	$330,584,231

* Jobs are presented in full-time equivalence (FTE)

6.5.2. Alternative 2b RED

Table 44 displays RECONS output for Alternative 2b. It is estimated that the project would create over 5,000 local jobs and nearly 9,000 jobs nationally. Total labor income in the U.S. would exceed $636 million, and value added would be nearly $837 million. Since the cost of Alternative 2b is higher than Alternative 1, Alternative 2b would have a greater regional economic impact.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Table 46. Alternative 2b Regional Economic Impact

Area	Jobs*	Labor Income	Value Added
Local			
Direct Impact	3,503	$294,565,103	$291,340,128
Secondary Impact	1,771	$111,377,185	$200,197,189
Total Impact	5,273	$405,942,288	$491,537,317
State			
Direct Impact	3,717	$295,233,879	$291,801,502
Secondary Impact	1,845	$113,348,163	$204,835,476
Total Impact	5,562	$408,582,041	$496,636,978
US			
Direct Impact	4,618	$343,612,557	$336,165,819
Secondary Impact	4,313	$292,447,966	$500,742,495
Total Impact	8,931	$636,060,523	$836,908,315

* Jobs are presented in full-time equivalence (FTE)

6.5.3. Alternative 5.3 RED

Table 45 displays RECONS output for Alternative 5.3. It is estimated that this alternative would create approximately 8,000 jobs locally and over 13,000 jobs nationally. Total national labor income from the project would be nearly $950 million and value added nationally would exceed $1.2 million.

Table 47. Alternative 5.3 Regional Economic Impact

Area	Jobs*	Labor Income	Value Added
Local			
Direct Impact	5,128	$439,031,743	$434,225,109
Secondary Impact	2,591	$166,001,061	$298,381,988
Total Impact	7,719	$605,032,804	$732,607,097
State			
Direct Impact	5,442	$440,028,513	$434,912,760
Secondary Impact	2,699	$168,938,686	$305,295,077

Total Impact	13,070	$948,010,328	$1,247,361,999

* Jobs are presented in full-time equivalence (FTE)

6.6. Nonstructural Alternative 6

In accordance with *USACE Policy Directive – Comprehensive Documentation of Benefits in Decision Document* issued 5 January 2021, a nonstructural plan that includes modified floodplain management practices was considered during the plan formulation process. The

nonstructural plan was identified by using HEC-FDA FWOP condition depths and damages, and aggregating structures by the reach and floodplain extent that had positive net benefits with nonstructural measures in place. The resulting plan consists of floodproofing 1,501 structures and elevating 43 structures in reaches AW1, AW2R, and AW7R above the 1% AEP flood stage. For reaches AW1 and AW2R, benefits were maximized when structures were aggregated using the 1% AEP flood extent. The 2% AEP event was used to aggregate structures in AW7R. Reaches not included in Alternative 6 did not have positive average annual net benefits. Table 48 displays the summary of measure for the nonstructural plan.

Table 48. Alternative 6 Nonstructural Measures Summary

Category	Reach AW1	Reach AW2R	Reach AW7R	Total
Number of Structures Elevated	8	32	3	43
Number of Structures Floodproofed	945	510	46	1,501
Total Number of Structures	953	542	49	1,544
Target Stage	1% AEP	1% AEP	1% AEP	n/a
Structure Aggregation Level (Floodplain)	1% AEP	1% AEP	2% AEP	n/a

7. Benefit Cost Analysis

7.1. Final Array Costs

Costs were prepared by cost engineering for each alternative in the final array. Interest during construction (IDC) was calculated for a six-year period of construction using an interest rate of 2.5 percent. Costs are shown in FY23 price levels and annual costs reflect a project life cycle of 50 years at the current discount rate of 2.5 percent.

Table 46 displays project costs for each alternative in the final array at the time of TSP selection. Total project first costs are $235 million for Alternative 1, $528 million for Alternative 2b, and $449 million for Alternative 5 at 2.5 percent. Annual costs including operation and maintenance are $9 million for Alternative 1, $20 million for Alternative 2b, and nearly $30 million for Alternative 5 at 2.5 percent.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Table 49. Final Array Costs by Alternative 2.5%

Category	Alternative 1	Alternative 2b	Alternative 5
Construction Cost	$163,572	$414,099	$374,790
Lands and Damages	$29,770	$8,711	$28,779
Planning, Engineering, and Design	$30,261	$76,608	$69,336
Construction Management	$11,450	$28,987	$26,235
Total Project First Costs	$235,053	$528,405	$499,140
Interest During Construction	$18,044	$40,564	$38,318
Total Gross Investment	$253,097	$568,969	$537,458
Annual Cost of Total Gross Investment	$8,924	$20,061	$18,950
Annual OMRR&R	$169	$208	$249
Average Annual Cost	**$9,093**	**$20,269**	**$19,199**

Note: values in $000s; FY23 price level

7.2. Final Array Benefit-Cost Analysis

Equivalent average annual benefits, the BCR, and net NED benefits are calculated during the evaluation process to identify the NED plan, or the plan which maximizes net NED benefits. Net benefits are calculated by subtracting average annual costs from average annual benefits and represent the contribution of the plan to national economic output. The BCR informs the economic feasibility of a project, and is an important metric used in decision making. A project is considered economically feasible if it has positive net benefits and a BCR of 1.0 or greater. Average annual costs and benefits, annual net benefits, and the BCR are presented in this section for the final array of alternatives.

Table 47 presents the benefit-cost comparison at a discount rate of 2.5 percent for the final array that was used to identify a Tentatively Selected Plan, and therefore includes Alternative 5, which is differentiated from Alternative 5.3. Alternative 5 results in $33.1 million in net NED benefits. The BCR for Alternative 5 is 2.7. Alternatives 1 and 2b result in $17.7 million and $23 million in net NED benefits, respectively.

Table 51 displays the benefit-cost summary for Alternative 6 by reach. Total first costs are $520 million. Average annual net benefits are $14 million, and the BCR is 1.8.

Alternative 5 is the NED plan and the Tentatively Selected Plan. It maximizes net NED benefits, OSE benefits in terms of life loss reduction, and RED benefits.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Table 50. Final Array Benefit-Cost Comparison 2.5%

Category	Alternative 1	Alternative 2b	Alternative 5

BCR	**1.5**	**1.7**	**7.8**	**1.8**

7.3. Tentatively Selected Plan Benefit-Cost Analysis

After the TSP was identified, the plan was optimized to reduce uncertainty in engineering modeling and real estate assumptions, and to reduce induced damages. As a result, floodwall alignments were updated in the H&H modeling, and the berm at the Ala Wai Golf Course detention basin was increased to allow for greater storage capacity, resulting in lower induced damages in Reaches 2R and 2L. The updated TSP was named Alternative 5.3. For a comprehensive summary of measures modeled in HEC-RAS for different iterations of the TSP, please see Appendix B of this report.

Table 48 displays updated costs for the optimized TSP, Alternative 5.3. Total project first costs are $775 million, and the average annual cost is $29.8 million at a 2.5 percent discount rate.

Table 52. TSP Cost Summary 2.5%

Category	Alternative 5.3
Construction Cost	$570,904
Lands and Damages	$58,089
Planning, Engineering, and Design	$105,617
Construction Management	$39,963

Benefit-Cost Ratio	**1.8**	**1.0**	**1.6**	**2.3**

7.4. Tentatively Selected Plan Project Performance and Damages by Event

Based on the analysis presented in the preceding sections, Alternative 5.3 maximizes net NED benefits, and maximizes positive impacts to OSE categories. This section presents project performance and event-based damages for the TSP.

7.4.1. With-Project Performance Tentatively Selected Plan

This section presents project performance for the TSP existing and future conditions. Table 50 presents project performance for the existing condition and shows that the probability of flooding in any given year is decreased significantly for reaches AW1, AW7L, AW7R, and AW9R with the project in place, compared to the without-project performance statistics. The long-term exceedance probability is also reduced in these reaches. The conditional non-exceedance probability, or probability that no flooding occurs given the occurrence of an event of the listed probability, increases in these same reaches.

Table 50 shows that future with-project performance statistics are nearly identical to the existing project performance statistics.

Table 56. Existing With-Project Performance Tentatively Selected Plan

7.4.2. TSP Residual Damages by AEP Event

Table 51 displays damages by event with the TSP in place for the future condition. With the TSP in place, damages are reduced in most reaches at the 10% AEP event. Approximately 1,200 structures experience a reduction in flooding at the 0.2% AEP event in reach AW1.

Table 58. EAD by Flood Event Future Condition

7.5. Induced Flooding

This section describes impacts from potential induced flooding and describes a mitigation solution. All induced flooding structure counts presented in this section exclude structures with less than 0.5 feet of induced water surface elevation (WSE) to account for model noise (grid cells with no true WSE change sometimes had a small decimal WSE change between with and without-project), and to acknowledge that there is uncertainty in first floor elevations and WSE.

7.5.1. Expected Induced Flooding Impacts

With the TSP in place, WSE would be induced slightly for certain events and reaches. Equivalent annual benefits shown as negative values in Table 37 indicate reaches where the reach FWOP EAD is less than the reach EAD with the TSP in place. Induced flooding generally occurs in areas that are flooding under the FWOP condition, and the additional water surface induced by the project is minimal for frequent events and larger for the least frequent events. Table 59 shows that the most frequent event at which a structure with no FWOP flooding becomes flooded is the 10% AEP event. There are 21 structures (out of nearly 6,000 in the floodplain) that have induced WSE at the 1% AEP event that don't experience FWOP flooding.

Table 59. Structure Count with Induced WSE and no FWOP Flooding

Damage Reach	AEP Event

7.5.2. Induced Flooding Mitigation

To address induced flooding, nonstructural measures could be implemented to prevent additional damage to structures. Single-family residential structures that are one or two story with no basement are recommended to be elevated. Commercial Structures are recommended to be dry floodproofed, and hotels and multi-family (apartment) structures are recommended to be wet floodproofed by evacuating the first floor. Table 62 displays the summary for mitigation measures for the 1% AEP event. No structures that are recommended for dry floodproofing have flood depths greater than four feet.

Table 62. Nonstructural Induced Flooding Mitigation 1% AEP

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

This document contains CONTROLLED UNCLASSIFED INFORMATION (CUI). It contains information that may be exempt from public release under the Freedom of Information Act (5 USC 552). It is to be controlled, stored, handled, transmitted, distributed, and disposed of in accordance with USACE policy relating to CUI information and it is not to be released to the public or other personnel who do not have a valid “need to know” without prior written approval of an authorized USACE official.

Executive Summary

The geology of the watershed is very complex, primarily due to the volcanic history and transitory depositional nature of the alluvial and marine soil deposits on the island. Unconsolidated deposits that are highly compressible are common throughout the project area. Some areas also include consolidated deposits (less compressible), while other areas include rock or rock-type deposits, such as coral (marine), tuff (volcanic ash), or basalt (volcanic lava flows) sometimes interbedded with the unconsolidated and consolidated deposits.

Limited boring information was available. The assumptions regarding subsurface conditions were based on the limited boring information, as well as nearby water wells when available. While subsurface conditions were assumed for the purposes of this report, it is critical to understand that the assumptions made herein are preliminary in nature and for feasibility purposes (proof-of-concept) only.

There is insufficient boring coverage at every measure location to develop detailed recommendations suitable for design purposes. Borings and laboratory testing to investigate the actual soil and rock conditions at each specific feature location will be required to refine or develop further designs. There is considerable risk that the subsurface conditions will vary from those assumed for the purposes of this report due to the limited boring information available, although it is believed that there was sufficient information available to confirm that the proposed general solutions are feasible (e.g., levees, I-wall, and macropile-supported L-walls). The details of those solutions will likely change from those presented here once actual soil and rock data is available (e.g., I-wall embedment depths may change, macropile lengths and diameters may change, or levee side slopes may increase or decrease).

I-walls are planned in areas away from the stream channels where the potential for erosion is low (e.g., at detention basin areas away from the streams). Planned I-walls are 6 feet tall with sheet pile (PZ22) embedment depths of 18 feet below grade where the surrounding grades are relatively flat or 24 feet below grade where the ground surface in front of the wall slopes down at 3H:1V. All sheet piles are equipped with driving shoes due to the possibility of boulders, cobbles, and other obstructions.

Along stream channels, macropile-supported L-walls are planned. The L-walls will be 6 to 9 feet tall (6 feet in most locations / 9 feet at Ala Golf Course near the canal) with a 12- to 13-foot-wide base supported on cased macropiles. Specifically, the macropiles are assumed to be 40 to 50 feet long and 16 to 18 inches in diameter with a 14-to 16-inch outer diameter X ½-inch thick full-length permanent casing and a full-length No. 11 all-thread center bar. The macropiles are assumed to be in two rows with 5-foot on-center spacing, with the first row vertical and the second row battered at 3V:1H to reduce lateral movement of the monolith. All reinforcing steel is assumed to be stainless steel or epoxy coated since the macropiles are a permanent installation.

Levees (berms) are only planned at the Ala Wai Golf Course where the severe space constraints that exist at all the other measure sites are less restrictive. The levees are 6 to 9 feet tall with a 12-foot-wide crown, and 3H:1V side slopes. The levee will include an inspection trench. The 9-foot walls are located in the lower regions of the site closer to the Ala Wai Canal.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

1. Project Information

The Honolulu/Waikiki Beach area has experienced repeated damage from flooding of the Manoa, Palolo, and Makiki streams, all of which drain to the Ala Wai Canal, which outlets directly to Mamala Bay (Pacific Ocean). The Ala Wai Canal is a 2-mile-long waterway constructed in 1928 to drain extensive coastal wetlands, allowing development of the Waikiki District.

The watershed encompasses 19 square miles (12,064 acres) and extends from the ridge of the Ko'olau Mountains to the nearshore waters of Mamala Bay (Figure 1-1). The Palolo stream includes the Pukele and Waiomao tributary streams; and the Makiki stream includes the Kanaha tributary stream.

Figure 1-1: Overview of Ala Wai Watershed

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

The headwaters for all these streams are in steep mountainous terrain where intense rainfall occurs. The streams also collect surface water from the extensive urban development concentrated in the main valleys and the lower elevations of the watershed. Due to the nature of the events and the characteristics of the drainage basins, flood events tend to develop and dissipate quickly. Floodwaters generally are up and down in approximately 3 to 4 hours on all the streams and approximately 10 to 12 hours on the Ala Wai Canal.

The two main problems identified for this project were the economic damages and elevated life risk resulting from riverine flooding along the Makiki, Manoa, and Palolo streams and the interplay between riverine and storm surge flooding along the Ala Wai Canal.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

2. Purpose

The purpose of this general reevaluation report and environmental assessment is to develop and analyze alternatives designed to reduce the on-going flood risks throughout the Ala Wai watershed for site-specific selected storm frequencies (instead of a 100-year event at all locations), including a no action plan, as well as various combinations of structural, non-structural, and natural and nature-based measures.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

3. Alternatives Considered

The team developed an array of individual measures that were then combined into alternatives that accomplished flood risk reduction through similar objectives (referred to as cornerstones for the purposes of the report). These cornerstone alternatives included the following:

- Alternative 1 – Storage Cornerstone.
- Alternative 2 – Conveyance Cornerstone.
- Alternative 3 – Tunnel Cornerstone.
- Alternative 4 – Natural- and Nature-Based Cornerstone.
- Alternative 5 – Hybrid Cornerstone.

The team elected to move forward with the following three alternatives for further evaluation based on the effectiveness of the alternatives to reduce flood events: Alternative 1, Alternative 2B, and Alternative 5. Each of these alternatives are comprised of various individual measures. Table 3-1 includes a list of the individual measures within the three alternatives that incorporate geotechnical components. Many of the individual measures are shared across multiple alternatives. Other measures, such as non-structural measures, may be included in these alternatives, but these other measures are not listed in Table 3-1 as there are no geotechnical components requiring further discussion or development in the Geotechnical Appendix. The preliminary alignments considered during the alternative consideration for each of the measures are shown in Figure 3-1 and Figure 3-2.

Table 3-1: Alternative Summary

Measure	Alternative 1	Alternative 2B	Alternative 5

Woodlawn Drive Floodwall	L-wall on Macropiles	6 ft	1,625 ft	--	1	--
Koali Road Floodwall	L-wall on Macropiles	6 ft	2,485 ft	--	2	2
Kaimuki High School Floodwall (Alt 1 – ties into golf course berm)	L-wall on Macropiles[4] (1,700 ft) / I-wall (2,700 ft)	6 ft	4,400 ft	--	0 to 2	--
Ala Wai Golf Course Detention[5]	Berm	6 ft	5,640 to 10,665 ft	--	0 to 2	3
Ala Wai Canal Floodwall (Alt 2B / Alt 5)	L-wall on Macropiles[4] (20,005 / 19,960 ft) / I-wall (4,740 / 4,180 ft)	6 ft	24,745 / 24,140 ft	--	9 to 12	6 to 14
Kaimuki Extension of Ala Wai Canal Floodwall (Alt 2B / Alt 5)	L-wall on Macropiles[4] (1,030 / 1,800 ft) / I-wall (2,330 / 1,460 ft)	6 ft	3,260 / 3,660 ft	--	--	--
Makiki Floodwall[5]	U-wall on Macropiles[6]	6 ft	883 ft	--	4	1

[1] Berms to be 6 feet tall and have side slopes of 3H:1V with a 12-foot crown. I-walls to be 6 feet tall and have 18-foot of sheet pile (PZ22) embedment where the surrounding ground is flat and 24-foot of sheet pile embedment (PZ22) where the ground in front of the wall slopes down 3H:1V. L-walls to be 6 feet tall with a 12-foot-wide base supported on 16-inch diameter by 40 feet long cased macropiles with a 14-inch outer diameter X ½-inch thick full-length permanent casing and a full-length No. 11 all-thread center bar. The macropiles to be in two rows with 5-foot on-center spacing, with the first row vertical and the second row battered at 3V:1H.

[2] The length of the measure and the number of road closures and drainage structures may vary because of slight alignment changes between the alternatives.

[3] Indicates the number of inlet and outlet structures.

[4] The L-wall on Macropiles will be used adjacent to the stream (where erosion is more of a concern) or adjacent or nearby to the existing canal wall where damaging to the existing wall is a concern while the I-wall will be used in areas away from the stream (i.e., where there is flat ground) or away from the existing canal wall.

[5] An in-stream diversion/weir will be included in Alternative 1.

[6] The Makiki Floodwall was added during the evaluation of Alternative 5.2 but removed in Alternative 5.3 due to the induced damages created by its addition.

[6] U-walls assumed to extend 6 feet above existing Makiki canal walls/surrounding ground surface and be similar to L-walls, with the exception of the following changes: the base thickness is reduced; the base width will vary to match the existing channel width; and all macropiles assumed vertical (no batter).

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

4. Tentatively Selected Plan (TSP)

The array of alternatives previously presented in Table 3-2 were evaluated by the team based on cost-benefit ratio (BCR) and net benefits. Based on that evaluation, Alternative 5 (Hybrid Cornerstone) was selected for further evaluation, development, and optimization into the TSP based on subsequent incremental benefits and induced damages analyses. For the TSP, some measures were eliminated (e.g., they could not be justified incrementally); the alignment of others were adjusted for optimization; and one measure was added to reduce induced damage considerations. Table 4-1 includes a summary of the features included in the TSP, which was designated as Alternative 5.2.

Table 4-1: TSP Feature Summary (Alternative 5.2)

Measure	Structure Type[1]	Maximum Height	Total Length	Number of Road Closures	Number of Drainage Structures[2]	Number of Flapgates[2]
Woodlawn Drive Floodwall	L-wall on Macropiles	6 ft	1,270 ft	1	--	--
Koali Road Floodwall	L-wall on Macropiles	6 ft	2,510 ft	2	2	2
Ala Wai Golf Course Detention	Berm (8,315 ft) L-wall on Macropiles[3] (1,861 ft)	6-9 ft	10,176 ft	1	5	5
Ala Wai Canal Floodwall[4]	J-wall on Macropiles[3] (17,125 ft) L-wall on Macropiles[3] (4,069 ft) Tieback I-Wall[3] (1,658 ft)	6 ft	22,852 ft	11	14	59

[1] Berms assumed to be 6 to 9 feet tall and have side slopes of 3H:1V with a 12-foot crown. Taller berms planned at lower elevations of the Ala Wai Golf Course along the Ala Wai Canal.
L-walls assumed to be 6 feet tall (except at Ala Wai Golf Course) with a 12-foot-wide X 40-inch-thick base supported on 16-inch diameter by 40 feet long cased macropiles with a 14-inch outer diameter X ½-inch thick full-length permanent casing and a full-length No. 11 all-thread center bar.
L-walls at the Ala Wai Golf Course assumed to be 9 feet tall with a 13-foot-wide X 44-inch-thick base supported on 18-inch diameter by 50 feet long cased macropiles with a 16-inch outer diameter X ½-inch thick full-length permanent casing and a full-length No. 11 all-thread center bar. The macropiles to be in two rows with 5-foot on-center spacing, with the first row vertical and the second row battered at 6V:1H
J-wall assumed to be the same design as 6-foot L-walls (i.e., same width, macropiles configuration, etc.), except the wall will include a 3-foot-tall concrete wall on the heel, with the 3-foot-deep area created between the front and rear walls backfilled with soil to create an elevated walkway along the Ala Wai Canal.
Tieback I-wall assumed to be toed into rock or extended 15 feet below the stream level using press-in technology (similar to the Giken Method) with PZ30 sheet piles and 50-foot-long angled ties at 7 feet on-center with a continuous HP12X53 waler located 6 feet below the streambank crest.

[2] Indicates the number of assumed outlet structures. It is assumed that existing storm drains larger than 36 inches will require a drainage structure (and positive closure). Smaller sizes may require drainage structures during future design phases.

[3] J-wall on Macropiles assumed to be used primarily along the Ala Wai Canal (but also along the north side of the Manoa-Palolo to Date Street). L-wall on Macropiles assumed to be used adjacent to streams where visibility of the canal is not a major consideration and where erosion is more of a concern, while the I-wall assumed to be used in areas away from streams where there is flat ground and erosion is not a concern; however, there are no I-walls in the TSP (see explanation in one of bullet points below). The Tieback I-Wall assumed where space limitations and vibrations are major considerations and prevent the use of the other wall types (i.e., specifically planned on the north side of Manoa-Palolo Stream from Date Street to Kapiolani Boulevard).

[4] The floodwall around the canal also accounts for four canoe closure structures.
The Ala Wai Canal measure for the TSP is a combination of the floodwalls along the Ala Wai Canal and along the Manoa-Palolo (including at Kaimuki High School).

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

The primary changes from the Alternative 5 selected and described in Section 3 to the TSP presented in this section and report (Alternative 5.3) were the following:

- Removal of the Kanaha Floodwall and the two detention basins (Makiki and Manoa) from consideration due to insufficient incremental benefits.
- Conversion of all the L-wall along the main Ala Wai Canal to a J-wall to create an elevated 3-foot-tall walking path combined with a 3-foot-tall wall behind the existing canal wall. The 6-foot wall was deemed an unacceptable barrier to a cultural resource (the Ala Wai Canal). The elevated walkway created by the J-wall restored visual connection with the Ala Wai Canal (a major concern of the local residents), while also significantly reducing some of the safety concerns expressed with a 6-foot-tall wall with limited access between the canal and the nearby streets (i.e., the ability to get from the water side to the land side of the wall quickly due to only having limited wall penetrations for doors and gates in consideration of the short duration and minimal notice of flood events). In addition, the additional dead load created by the elevated 3-foot-tall walkway will help reduce lateral deflection of the pile cap, which will reduce potential impacts on the existing (sensitive) canal wall.
- Conversion of the L-wall along the north bank of the Manoa-Palolo Stream from Date Street to Kapiolani Boulevard (which is considered part of the Ala Wai Canal Floodwall alignment) to a press-in, tieback I-wall due to insufficient space to construct the originally planned L-wall. The press-in I-wall, using technology similar to the Giken Method, requires less footprint for construction (equipment rides along installed sheet pile) and permanently (I-wall only requires 2 to 3 feet versus 12 feet for wide L-wall). In addition, the press-in technology allows sheet pile to be pushed hydraulically, instead of driven, reducing vibration concerns for nearby structures.
- Conversion of the I-walls originally planned around the Kaimuki High School playing fields to L-walls for simplicity and continuity of the system (e.g., to avoid transition points since limited length of I-wall necessary and reduce the types of floodwalls used).
- Extension of the Koali Road from the pedestrian bridge at Kaluawaa Street to St. Louis Drive due to lower ground elevations than originally assumed.
- Taking of 2/3 structures (one residential structure, one commercial structure, and one small structure of indeterminate origin) immediately north of Kapiolani Boulevard due to their proximity to Manoa-Palolo and the inability to construct a flood reduction system between the structures and the creek without permanent construction into the creek (and permanently impinging creek flow, which would cause damages upstream) and the inability to safely construct a wall around the structures (thereby excluding them from flood reduction system) due to the required sightlines at the intersection and the limited space for appropriate wall set-back from the street.
- Increase in wall/levee heights at the Ala Wai Golf Course to increase detention volume.

The proposed alignments for each measure included in the TSP are included in Figure 4-1. Zoomed in views of the individual alignments are included in Figure 4-2 to Figure 4-4 for further reference. The types of risk reduction for each measure are shown in Figure 4-5.

5. General Geology

5.1. Overview

The following general geology description for the project area was provided in the Interim Final Report for the Feasibility Study with Integrated Environmental Impact Statement, prepared by USACE, dated May 2017 (USACE, 2017b):

> The Ala Wai Watershed lies on the southern slope of the Koʻolau volcano, the younger and more easterly of two shield volcanoes that built the island of Oʻahu. Much of the eastern side of the Koʻolau volcanic shield has been removed through erosion and structural collapse; the remnants form the Koʻolau Mountain Range.
>
> The Koʻolau Mountain Range has been deeply dissected by erosional forces, resulting in gullies and gulches separated by steep ridges. Tributary streams generally originate in the upper elevations of the watershed and join to form single master streams (such as Manoa Stream), converging in deep and wide valleys.
>
> Alluvial soil from the ridges and mountainous areas has been gradually removed by sheet erosion and transported to the lower valley floor by surface runoff, accumulating as thick alluvial sequences.
>
> The Honolulu coastal plain, which generally extends from Pearl Harbor to Koko Head, is comprised of interlayered terrigenous *(material eroded from land)* and marine sediments and calcareous materials, as well as volcanic deposits produced by rejuvenated-stage volcanism (Stearns, 1939).

The geology of the watershed is very complex, primarily due to the volcanic history and transitory depositional nature of the soil deposits on the island. For example, volcanic eruptions resulted in lava flows or ash ejection from a vent. These volcanic deposits often were irregular in both lateral and vertical extent. In some locations, the volcanic activity impacted surface water flow or soil deposition. Soil deposits were influenced by stream flow and erosion, marine activities (e.g., rise and fall of sea levels), and backwater influences. For example, alluvium is interlayered with coral reef deposits and other marine sediments; and these deposits may be interlayered with volcanic-related sediments or rocks. In addition, a large portion of the coastal plain within the project site reportedly is fill. The fill is largely underlain by younger, underconsolidated alluvium, marsh, and lagoonal deposits. A general overview of the geology of the Ala Wai watershed is shown in Figure 5-1.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Figure 5-1: Geology of Ala Wai Watershed

Listed below are the mapped geologic units identified below the individual measures based on the Geologic Map of the State of Hawai'i:

- (Holocene) Alluvium.
- Calcareous Reef Rock and Marine Sediment (Pleistocene).
- (Holocene) Fill.
- Lava Flows (Ko'olau Basalt).
- Lava Flows (Tantalus Peak and Sugar Loaf Vents).
- Lava Flows.
- Tuff.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

More detailed discussion of the mapped geologic units underlying the individual measures is provided in Section 0 where details regarding the individual measures are provided. The geologic information presented in Section 0 was obtained from the Geologic Map of the State of Hawai'i (USGS, 2007).

5.2. Engineering Properties & Construction Considerations

The following sections include a general discussion of the engineering properties and construction implications associated with each identified unit based on information provided in Sue Finstick's 1998 report entitled "Project Completion Report for Subsurface Geology and Hydrogeology of Downtown Honolulu: Engineering and Environmental Implications, Phases I and II", referred to herein as the Finstick Report.

Discussion of the Coralline Debris, Coral Ledges, Cinders, and Residual Soils/Weathered Volcanics deposits also is included since these deposits are present along the Ala Wai Canal and may be penetrated or relied upon for support of the planned macropiles. These units were not specifically identified or differentiated on the Geologic Map of the State of Hawai'i.

5.2.1. (Holocene) Alluvium

The Finstick Report stated the following regarding the engineering properties of the (Holocene) Alluvium:

> (The alluvium is) "a fairly heterogeneous unit, with variable engineering properties … alluvial deposits almost always include abundant cinders … Consolidation values reported are variable but tend to be high, indicating that this unit can be compressible. … Underconsolidated alluvial deposits are often found at shallower elevations, are more recent, and are characterized by low strength and high plasticity. …

The Finstick Report stated the following regarding the implications for construction in the (Holocene) Alluvium:

> Alluvial deposits are fairly heterogeneous, but in general, this subsurface unit is easy to excavate. The only difficulty in excavation would be caused by abundant boulders, but these occur in localized areas only. Alluvial deposits can be underconsolidated and compressible … In general, it is better to bypass this unit and utilize a deeper, more competent foundation-bearing layer, such as basalt or a coral ledge. However, this is often not possible … Friction piles, which derive their resistance from skin friction or adhesion, driven to the deeper and more consolidated alluvial deposits, can be used in these circumstances. However, the successful use of friction piles requires a thorough site investigation, combined with good judgment and experience …

Further, the Finstick Report stated "The slopewash alluvium, found at the *mauka* edge of the study area at higher elevations, is generally only a few feet thick. In boring logs this material may be referred to as "adobe." … The adobe found in the slopewash alluvium at higher elevations is highly compressible and should be excavated prior to construction." *Mauka* means "inland, upland, toward the mountain", which for that study meant the northern edge of the study area. The study area for the Finstick Report was bounded by Kalihi Stream to the west, Highway 1 to the north, Kalakaua Avenue and Atkinson Drive to the east, and the Pacific Ocean to the south.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

5.2.2. Tuff

The Finstick Report stated the following regarding the occurrence of Tuff:

> …It is generally found just below the cinders. …

The Finstick Report stated the following regarding the engineering properties of Tuff:

> In general, tuff is a hard, competent rock, with high strength and low compressibility. … The average rock quality designation was only 36%, which classifies it as "poor," although values were logged as high as 88%, which is in the category of "good." … Compressibility is generally not a factor for tuff in an unweathered state; however, weathered tuff may be moderately compressible.

The Finstick Report stated the following regarding the ease of construction in Tuff:

> Ease of excavation, as well as the overall strength of the tuff, depends upon the degree of weathering and fracturing and the amount of cementation within the unit. In the unweathered state, tuff is hard and strong, making it difficult to excavate. Weathered and fractured tuff is easier to excavate but may cause problems if used as a foundation-bearing layer due its softer and weaker nature. The top few feet of a tuff unit is often highly weathered … Open excavations generally do not need bracing, and the low permeability of tuff means that dewatering the unit is not difficult.
>
> A detailed site investigation is necessary to reveal the quality of the tuff at a specific location. In addition, information on the degree of weathering, fracturing, and cementation, as well as total thickness of the unit and any variations in thickness at the site, is needed to determine the foundation design.

5.2.3. Basalt

The Finstick Report stated the following regarding the occurrence of Basalt:

> Within the study area, there are at least four different basalt lava flows that date from the Honolulu Volcanic Series post-erosional or rejuvenation period. No boring logs examined for this study mentioned boreholes deep enough to reveal the much older Ko'olau basalt. Both ʻaʻā and pahoehoe flows were encountered in the subsurface; however, the logs made no attempt to distinguish between the two types of flows. All four of the Honolulu Volcanic Series basalt lava flows are generally oriented perpendicular to the shoreline.

ʻAʻā are lava flows that have a rough rubbly surface composed of broken lava blocks called clinkers. Pāhoehoe is basaltic lava that has a smooth, hummocky, or ropy surface.

The Finstick Report stated the following regarding the engineering properties of Basalt:

> Blow counts are high for basalt and are often recorded as blows per inches or fraction of a foot rather than as blows per foot … compressive strengths are also high. … Ferrall (1976) quoted compressive strengths for dense unweathered basalt as high as 30,000 pounds per square inch (4,320,000 pounds per square foot) for the Waikiki-Mo'ili'ili-Kaka'ako area. In this study strength values were found as high as 25,840 pounds per square inch (3,720,960 pounds per square foot), averaging over 17,000 pounds per

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

> square inch (2,456,868 pounds per square foot). Rock quality designations reported in the boring logs range from 17% to 100%, averaging 59%, which puts it in the category of "fair." However, this includes measurements taken from ʻaʻā clinker and weathered zones at the top and sides of the flow. The interior of the flow is more dense and is characterized by the higher values. Basalt is not compressible. … Reports surveyed for this study recorded allowable pile-bearing capacities of 100 to 200 tons per pile for l6.5-inch or l8-inch octagonal piles. Ferrall (1976) also reported allowable pile capacities of up to 200 tons per pile for the Waikiki-Mo'ili'ili-Kaka'ako area.

The Finstick Report stated the following regarding the ease of construction in Basalt:

> Excavation of basalt is difficult, as it is the hardest and strongest unit found in the subsurface of the study area. It is an excellent foundation-bearing material. Shallow footings can be used in areas where the basalt is at or near ground surface. For basalt found at depth, piles are often used to support structures bearing on the basalt. Piles used in the study area range from 40 to 130 feet long. When designing, it is recommended that the possibility of the presence of compressible material below the lava be considered, as settlement could occur. Predrilling through overlying materials such as coral may be necessary when placing piles to basalt. An adequate site investigation must be performed to determine the thickness of the lava flow in any area. The presence of weathered layers, lava tubes, abundant vesicles, and ʻaʻā clinker layers may decrease the strength of the basalt and should be considered when designing structures for construction on basalt.

5.2.4. Residual Soils / Weathered Volcanics

The Finstick Report stated the following regarding the occurrence of Residual Soils or Weathered Volcanics:

> Residual soil or weathered volcanics comprise the weathered or decomposed uppermost surface of tuff and basalt deposits. This material is generally only a few feet to about 10 feet thick. It overlies unweathered tuff and basalt in the study area. It often includes weathered ʻaʻā clinker and mottled orange-brown clayey silt with basalt gravel and cobbles, such that it is probably an alluvial soil that formed on top of the volcanics. This unit grades down to the unweathered volcanic material with depth.

The Finstick Report stated the following regarding the engineering properties of Residual Soils or Weathered Volcanics:

> Blow counts, strengths, and dry densities for weathered volcanics tend to be comparable to or lower than those of their unweathered counterpart. The residual soils exhibit engineering characteristics similar to those of alluvium. This unit may be moderately compressible when compared to the unweathered volcanic material found below it. …

The Finstick Report stated the following regarding the ease of construction in Residual Soils or Weathered Volcanics:

> In general, weathered volcanics have characteristics similar to, but usually weaker and softer than, those of their unweathered counterparts. Therefore, excavation of this material is easier. However, its use as a foundation-bearing layer is not advised. Since

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

this material is generally only a few feet thick and overlies denser and more competent tuff or basalt, bypassing it and utilizing the unweathered volcanic material as the foundation-bearing layer is usually not a problem.

5.2.5. Coralline Debris

The Finstick Report stated the following regarding the occurrence of the Coralline Debris:

> In general, coralline debris is found paralleling the coast and extending up former stream valleys. It is often found above and below coral ledges, intermixed with alluvial deposits, and within lagoonal layers. The thickness of this unit is extremely variable, ranging from lenses as thin as 1 foot to thick sequences of 50 feet or more. The thicker deposits are often found interlayered with alluvial deposits … Coralline debris consists primarily of silty calcareous sand and gravel. …

The Finstick Report stated the following regarding the engineering properties of the Coralline Debris:

> The engineering properties of coralline debris depend to a large extent upon its degree of cementation. … The rock quality designation for coralline debris is highly variable but averages only 17%, which puts it in the category of "very poor." … Compressive strengths for coralline debris are also variable, again reflecting the degree of cementation as well as the intermixing of coralline debris with other subsurface units. … no generalizations can be made about compressibility of this unit. However, it can be assumed that if intermixed with compressible alluvial deposits or lagoonal materials, coralline debris can undergo significant consolidation. …

The Finstick Report stated the following regarding the ease of construction in the Coralline Debris:

> The ease of excavation of coralline debris depends on the degree of cementation, as this material may be weakly cemented and relatively soft or well-cemented and hard. The degree of cementation, thickness, and intermixing with soft materials also determines the suitability of this material as a foundation-bearing layer. There can be rather extreme variations in the degree of cementation within a lens of coralline debris, and this can vary abruptly in both the horizontal and vertical directions within a deposit. Each site needs to be carefully examined for the degree of cementation, strength, and compressibility of this material. Reports surveyed for this study recommend using shallow or mat foundations for low-rise structures and piles for high-rise buildings.

5.2.6. Coral Ledges

The Finstick Report stated the following regarding the occurrence of the Coral Ledges:

> The -30 coral ledge is defined as that hard and dense ledge first encountered between elevations of -30 and -50 feet. In the study area, it is as thin as 3 feet and as thick as 35 feet, averaging about 15 feet thick. It parallels the shoreline and is the most seaward ledge coral mapped. It is also more prevalent in the eastern part of the study area than toward the western side.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Massive ledge coral first encountered between elevations of -15 and -29 feet is classified as the -15 coral ledge. The thickness is variable, ranging from 2 to 30 feet and averaging about 12 feet. This coral ledge also parallels the coast and is located just inland of the -30 coral ledge. It is also primarily found in the eastern part of the study area.

Ferrall (1976) referred to coral found as high as +10 feet as part of the +5 ledge. Therefore, for this study, the +5 coral ledge is defined as that ledge first encountered between elevations of +10 and -10 feet. This ledge, which also parallels the shoreline, is found inland of the -15 coral ledge. The thickness is highly variable, ranging from about 1 to 42 feet and averaging 15 feet. It appears in the subsurface as a band from the eastern part of the study area clear through to the western part. In the eastern part of the study area, it is found as far *mauka* as the H-l Freeway in some places. Toward the western side of the study area, it is located closer to the shoreline.

The Finstick Report stated the following regarding the engineering properties of the Coral Ledges:

The coral ledges are characterized by some of the highest blow counts of any material in the study area. Their compressive strengths … are also high … Their rock quality designations vary from 0% to 100%, indicating a wide range in in situ rock quality, but the averages fall between "poor" and "good." No consolidation values were recorded for coral ledges in the reports surveyed for this study. … Allowable pile-bearing capacities found in reports used for this study ranged from 40 to 200 tons per pile. Ferrall (1976) reported the use of pile capacities between 40 and 100 tons per pile and concluded that pile capacities up to 100 tons per pile were acceptable on the coral ledges in the Waikiki area. However, he also stated that this figure may be too high in some cases, due to excessive settlement beneath and within the coral for loads this high. Therefore, the use of pile-bearing capacities as high as 200 tons per pile found in this study may be questionable.

Although coral ledges are among the hardest and strongest of the subsurface units within the study area, there are a number of problems associated with the use of coral ledges as foundation bearing layers. The most common are inconsistent thickness, areal extent, and hardness. Ledge coral at a site can vary from only a few feet to more than 10 feet in thickness, and it often has solution cavities that may be partially filled with soft sand. The degree of cementation and the amount of fracturing are also highly variable, both in the vertical and lateral directions. Often, the only distinction between ledge coral and coralline debris is the degree of cementation, which is reflected in blow counts. Therefore, there are probably many instances of ledge coral being misidentified as coralline debris and vice versa. However, for the purposes of this study, ledge coral is defined as that hard and dense coral characterized by blow counts of over 50 blows per foot (Dames & Moore system, 140-pound weight falling from a height of 30 inches), a rock core recovery of over 50%, and a rock quality designation of over 40%. In the consultants' reports surveyed for this study, this was the most common definition used to classify coral ledge.

… It is obvious that although the coral ledge is in general a hard and dense unit, there can be many irregularities in the strength of this material. Only a thorough site

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

investigation can reveal the various irregularities so that the foundation can be properly designed.

The Finstick Report stated the following regarding the ease of construction in the Coral Ledges:

> The ease of excavation depends on the degree of cementation and fracturing of the coral ledge. In general, this material has enough in situ strength to allow excavation without bracing the sides of the excavation pit. Uncemented material may slough off into the excavation pit. If hard and well-cemented, excavation may be difficult.
>
> One of the problems associated with using the coral ledge as a foundation-bearing layer is the presence of cavities. If the cavities are filled with soft sand, the ledge may be compressible, resulting in differential settlement of the foundation. Piles driven into these cavities may fall through and thus not bear any of the weight of the foundation. Therefore, the coral ledge may need to be probed to delineate these cavities; if present, the cavities may require infilling with concrete or cement grout prior to construction at the site. For well-cemented, dense coral ledges without cavities, settlement is generally not an issue. Dewatering of coral ledges may be difficult due to their relatively high hydraulic conductivity.
>
> For low-rise structures, shallow foundations such as spread, mat, or continuous footings have been used on the coral ledges at or near ground surface. For high-rise buildings, end-bearing piles have been used on the coral ledges. Short piles (less than25 feet) with low allowable bearing capacities (50 tons per pile) have been used on the +5 coral ledge.
>
> Because of the variation in thickness and degree of cementation, many of the site reports examined recommend bypassing the upper coral ledge and using deeper coral ledges as the foundation-bearing stratum for piles. This requires predrilling through the upper coral ledge in order to place end-bearing piles on the lower ledges. …

5.2.7. Cinders

The Finstick Report stated the following regarding the occurrence of Cinders:

> Black cinders, although widespread in the study area, are primarily located in the east-central part, between Pi'ikoi Street on the east and Nu'uanu Avenue on the west, within the Kaka'ako and downtown Honolulu districts. Cinder deposits in the study area are generally located below the fill and alluvial topsoil layer. They are also located below the lagoonal materials in regions where such sediments occur.
>
> However, they are often found above the coral ledges. Cinders are of variable thickness, ranging from 0.5 to 55 feet, but averaging between 5 and 10 feet in the study area. The thicker deposits, which occur toward the *mauka* side of the study area, are found as reworked cinders within the old alluvial channels …

The Finstick Report stated the following regarding the engineering properties of Cinders:

> There is a great range in blow counts for cinders, reflecting the degree of compaction and cementation of the deposits. In some locations, the Tantalus/Roundtop cinders are still in a loose, uncompacted condition. In other locations, the cinders have been

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

> compressed and cemented to a hard and dense state. … Values for strengths vary widely, again reflecting the degree of cementation as well as intermixing with other subsurface units, especially alluvial deposits. … In general, consolidation is low for cinders. However, when uncemented and uncompacted and when intermixed with compressible materials such as unconsolidated alluvial deposits or lagoonal deposits, cinders can be expected to undergo settlement.

The Finstick Report stated the following regarding the ease of construction in Cinders:

> Ease of excavation of cinders depends on the degree of cementation. In general, this material is easy to excavate and can be a good source of clean, stable backfill. The use of cinders as a foundation-bearing layer is usually not recommended, due to the loose, uncompacted nature of much of this material. In particular, when cinders are found intermixed with alluvial deposits or lagoonal materials, consolidation and the resulting settlement of the structure must be considered. … friction piles, as suggested for alluvial deposits, that derive their resistance from skin friction or adhesion. … For excavations requiring dewatering, this unit may cause problems, as it is permeable and therefore will be difficult to dewater.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

6. General Subsurface Conditions

In general, there was no boring or water well information regarding the specific subsurface conditions at half of the measure locations (4 out of 8) considered in the alternative array. At the remaining alternative array measure locations (4 out of 8), there were borings in the general vicinity of the measures, but not necessarily at the specific measure locations. As such, at these locations some reasonable conclusions could be made about the general soil conditions in the area of those proposed measures; however, in no case was the boring coverage considered sufficient for design purposes. It is important to note that due to the natural variability in the subsurface conditions resulting from the complex geology and the insufficient boring coverage, there is considerable risk that the subsurface conditions will vary from those assumed for the purposes of this report.

The following is an example of where boring coverage existed but was not necessarily along a specific measure alignment: There were borings for an auditorium addition at Kaimuki High School (Hardin-Lawson Associates, 1976) and for a maintenance facility at the Ala Wai Golf Course (Fewell Geotechnical Engineering, 1993). The borings for both of these projects were located in the general vicinity of the proposed Kaimuki High School Floodwall (Figure 6-1). Most of the borings generally were 200 feet or more from the proposed alignment. In addition, the borings provided coverage for less than a quarter of the proposed alignment. Furthermore, the subsurface conditions varied in the borings between the high school and golf course (e.g., coralline deposits encountered in maintenance facility borings, but not the auditorium borings) and even between the borings at the individual sites (e.g., 80 feet of alluvial deposits encountered in most borings at the auditorium, but a rock shelf encountered at 45 feet in one boring). In both cases though, surface deposits consisted of low shear strength, highly compressible soils.

Figure 6-1: Kaimuki High School Floodwall & Nearby Borings

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

The assumed subsurface conditions provided for the individual measures detailed in Section 0 were obtained from nearby borings or wells, if available, and from the nearest borings or wells in similar geology for measures where there was no nearby subsurface information. However, as noted previously, the subsurface conditions were found to vary significantly over short distances (e.g., depth to rock varied, soil types varied, and consistency/density varied), emphasizing the need for borings to confirm preliminary design assumptions and to further refine the design during the design phase. Similarly, caution regarding assumptions related to subsurface conditions in absence of sufficient boring data and coverage is warranted.

For the purposes of this report, due to the variability in subsurface layering and the apparent wide-spread presence of soft and loose deposits, designs were evaluated assuming all surface soils were comprised of highly compressible layers with poor support characteristics. The surface soils likely are comprised of intermixed and interbedded fine and coarse-grained soils, including some (e.g., consolidated deposits) that are higher quality than assumed for the purposes of this report. For the purposes of this report and because the actual soil layers are unknown, designs were evaluated assuming the presence of soft fine-grained soils throughout the soil column or loose coarse-grained deposits throughout the soil column, with the most conservative resulting design selected for the feasibility phase of the work. In other words, I-walls and macropiles for L-walls were designed for soft clays or loose sands throughout the entire soil column. The greatest embedment depth and diameter/sizing resulting from each design condition was selected.

It is noted that design parameters selected for these preliminary analyses were, at best, loosely based on available laboratory testing, which was very limited. Design parameters were assumed and assigned based on the concept that the soil column generally was expected to be comprised of highly compressible soils with poor support characteristics. The design was based on the assumed values summarized in Table 6-1. It will be important that sufficient laboratory testing be conducted during the design phase to determine actual soil and strength characteristics. The assumed soil parameters summarized in Table 6-1 are considered conservative and generally are lower than those reported in the Finstick Report and the other site-specific geotechnical reports listed in Section 12.

Table 6-1: Assumed Soil Parameters

Soil Types	Unit Weight (pcf)	Effective Friction Angle f ' (degrees)	Effective Cohesion c' (psf)	Total Friction Angle f (degrees)	Total Cohesion c (psf)
Soft Clay	100	20	100	0	500
Loose Sand	100	30	0	30	0

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

7. Geotechnical Concerns

7.1. Lack of Subsurface Information

As described in more detail in Section 0, very little to no specific boring/subsurface information was available for the particular measure sites for this project. Due to the natural variability in the subsurface conditions resulting from the complex geology and insufficient boring coverage, there is considerable risk that the subsurface conditions will vary from those assumed for the purposes of this report.

The subsurface conditions assumed for the purposes of this report were based on the conditions encountered in the closest available borings and wells deemed appropriate for these purposes (instead of actual boring information along the proposed alignment). As such, borings must be advanced at suitable spacings and depths to better determine actual subsurface conditions for design or purposes beyond feasibility purposes.

It will be important that the borings identify the characteristics (strength, cementation, continuity, etc.) of any rock-like deposits encountered (e.g., coral, lava, tuff, etc.) due to the irregular nature of these deposits, especially if macropiles are end-bearing on the formation.

7.2. Soft, Loose, Compressible Deposits

One common theme in many of the borings from nearby sites was the presence of soft or loose alluvial, marine, or lagoonal deposits. These deposits often were encountered near the ground surface and well within anticipated foundation influence zones. In addition, these soil deposits often were thick.

Soft or loose soils tend to have low strength, resulting in low strength parameters that often control the design. In addition to low strength, these soils tend to be highly compressible, resulting in total and differential settlement concerns that must be included in the design. Furthermore, these soils tend to make the construction process more difficult and costly (e.g., a construction platform of granular soils may be required for surface stability; flatter excavation slopes may be required for safety; or installation of an improved zone directly below foundations may be required). The presence of these types of deposits undoubtedly will impact the proposed design and construction at most, if not all, the sites.

7.3. Boulders & Obstructions

Some of the geologic formations include large boulders, lava flows, or other hard-to-penetrate layers (e.g., cobbles or gravel) that will complicate installation of deep foundations because they come “obstructions” to advancement of deep foundation elements, such as macropiles and sheet piles. This is one of the reasons that macropiles are the preferred foundation type and is also why it is recommended that sheet piles be fitted with driving shoes. This concern likely will impact the proposed construction at most, if not all, the sites.

7.4. Groundwater

Shallow groundwater (often from 1 to 3 feet below existing grades) was common in the area of the Ala Wai Canal and Ala Wai Golf Course and may be encountered at other sites. Shallow groundwater often complicates construction, requiring special excavation and stabilization

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

measures. In addition, cut slopes typically are cut flatter where groundwater is encountered. The presence of shallow groundwater is expected to significantly impact construction in the Ala Wai Canal and Ala Wai Golf Course area due to the expected difficulty dewatering excavations.

Groundwater, if encountered, may be challenging to address in some of the geologic formations underlying the site, such as the Coral Ledges and Cinders due to the porosity of the formations.

Artesian conditions are a known problem in the Honolulu area. The artesian conditions typically are associated with aquifers expected to be below the construction depths for this project. However, due to the complex geology and artesian conditions in localized areas, it will be important that future exploration plans and studies at least include evaluation of the possibility of artesian conditions, especially since artesian conditions can be detrimental to the proposed construction if not properly addressed in design (e.g., water may seepage upwards continuously along sheet piles or macropiles).

7.5. Mo'ili'ili Karst

There is an area known as Mo'ili'ili Karst in Honolulu. The area generally is centered near University Avenue and S. King Street as shown in Figure 7-1. This area is known to have caves, which have impacted foundation installations in the area and caused surface subsidence (to a lesser degree). The karst activity likely is associated with the calcareous reef rock, which reportedly is at relatively shallow depths in this area. While several of the proposed measures are located nearby (Koali Road Floodwall, Kaimuki High School Floodwall, Ala Wai Golf Course, and Ala Wai Canal Floodwall as shown in Figure 7-1), none of the proposed measures are expected to be impacted by Mo'ili'ili Karst or other karst activity.

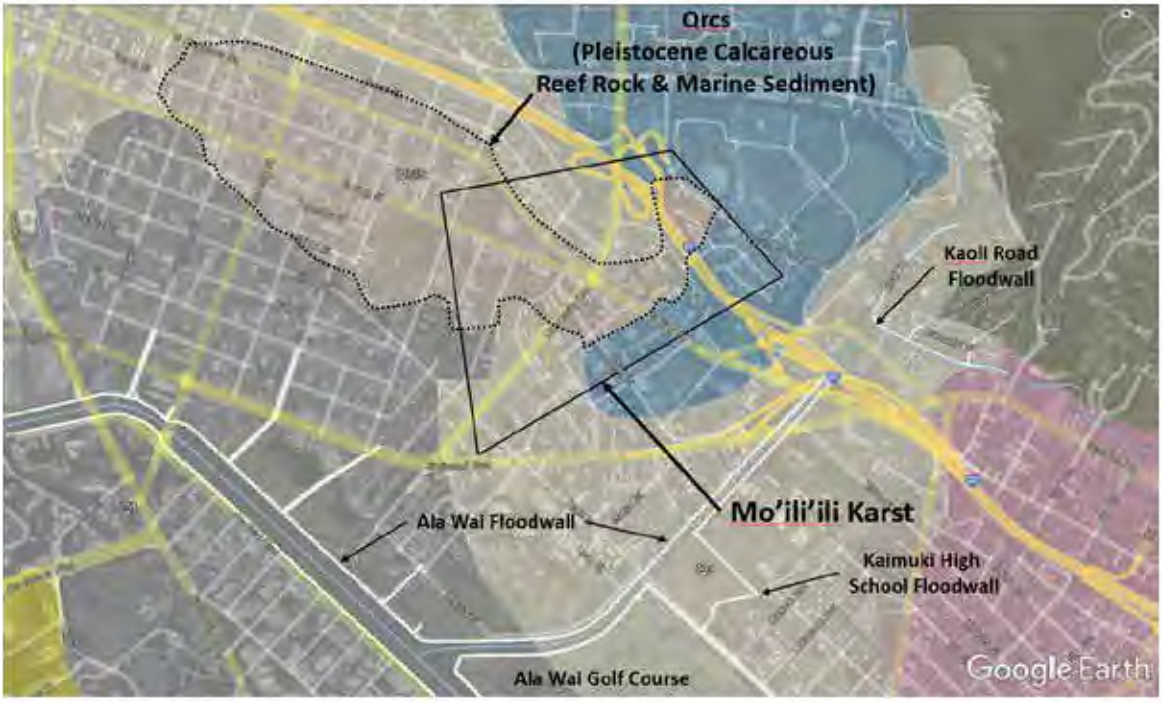

Figure 7-1: Mo'ili'ili Karst

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

8. Structural Features

The following structural feature types were included in the alternative array analysis: I-walls, L-walls, J-walls, U-wall, Press-In/Tieback I-walls, levees, and detention basins. Additional information on each of these features is provided in the following sections.

8.1. I-Walls

I-walls generally were assumed when walls were needed to create storage basins, while L-walls were assumed when walls were located adjacent to streams due to concerns about erosion removing the soil in front of the I-wall that may be necessary to provide lateral resistance. I-walls also were considered where the wall was located far enough away from the stream that bank erosion was not a concern. The “short” section of I-wall that had been planned around the playing fields at Kaimuki High School was converted to L-wall for simplicity of design (e.g., avoid transition and reduce the type of walls used). No I-walls were included in the TSP.

EM 1110-2-6066 (USACE, 2011) states that “I-walls shall be used only in instances where other flood barrier types are impractical.” For this project, I-walls were only used where space constraints were not conducive to other wall types. These other wall types require more real estate or the relocation of utilities. In addition, EM 1110-2-6066 requires the minimum wall embedment on natural (or flat) ground, be twice the stick-up wall height or 10 feet, whichever is greater, or 2.5 times the stick-up wall height on the protected side on levees (or sloped) ground or 10 feet, whichever is greater. Furthermore, EM 1110-2-6066 states the maximum unsupported stem height for new I-walls constructed on existing levees (or sloped ground) or in soft soils be limited to 6 feet. This height is limited to 4 feet on levees in the newer EM 1110-2-2502 published in 2022.

According to Table 9.4 of EM 1110-2-2502 (USACE, 2022a), the maximum allowable I-wall height varies based on the undrained soil strength and the load category as shown as in Figure 8-1. Based on this table, the maximum wall weight for the soft clays assumed to be present on-site (undrained strength, s_u = 500 psf) is 5.5 feet using linear interpolation between an undrained strength of 300 and 1,500 psf and a “usual” load category. The maximum height selected for structural features for this project was 6 feet based on a combination of hydraulic needs, the limitations associated with the use of I-walls, the maximum height perceived to be acceptable to residents, and expected space constraints. Additional hydrology and hydraulic (H&H) analysis will be required to refine the wall height. Refer to the H&H Appendix for more information on the H&H assumptions. It is noted that the assumed undrained strength for the on-site soils likely is conservative, such that a 6-foot wall is expected to be feasible once soil borings and laboratory testing are conducted.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Table 9.4
Maximum Wall Heights for Deformation Control of Cantilever Pile Walls Used for Floodwalls, Dam Walls, and Dam Crest Walls

Load Category	Foundation Type: Sand $\phi' \geq 32.5$, $D_r \geq 0.50$	Soft Clay $s_u \leq 300$ psf	Stiff Clay $s_u \geq 1,500$ psf	Wall on Earthen Levee Embankment
Usual	7 ft. (2.1 m)	5 ft. (1.5 m)	8 ft. (2.4 m)	4 ft. (1.2 m)
Unusual	9 ft. (2.7 m)	7 ft. (2.1 m)	12 ft. (3.7 m)	4 ft. (1.2 m)
Extreme	11 ft. (3.4 m)	8 ft. (2.4 m)	15 ft. (4.6 m)	4 ft. (1.2 m)

Notes:

(a) D_r = relative density

(b) The heights in the table are the distance from the elevation of the top of wall to the ground surface on the landside of the wall, as shown in Figure 9.12.

(c) Linear interpolation is permitted for clay strengths between those shown, but extrapolation is not permitted.

(d) Limited data has been developed for deformation of walls on levees. Walls on levees with heights greater than 4 ft. (1.2 m) as shown in Figure 9.12 require analysis by full numeric analysis methods.

(e) For layered soils, the engineer will base the maximum height on the predominant soil type resulting in the lowest water height for deformation control. The soil type used is determined by the soil on the landside of the wall extending from the ground surface to the elevation of maximum net passive pressure from the CWALSHT or CI-WALL analysis. Questionable sections will require analysis by full numeric analysis methods.

(f) Walls founded in soils with properties outside the range of soils in the table must be analyzed with full numeric analysis methods.

Usual loads are normal loads that are routinely experienced.

Unusual loads are rare, but likely during the service life of a structure.

Extreme loads are possible, but unlikely during the service life of a structure.

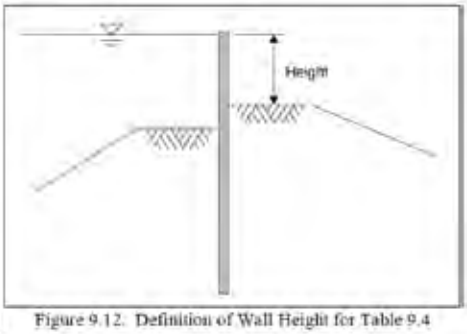

Figure 9.12. Definition of Wall Height for Table 9.4

Figure 8-1: Maximum I-Wall Heights per EM 1110-2-2502 (USACE, 2022a)

The required embedment depth was calculated for two conditions: level ground (Manoa Valley District Park Detention) and 3H:1V sloped ground on the water side of the wall (Makiki District Park Detention). In addition, embedment in all clay or all sand deposits was evaluated. In summary, CI Wall was used to calculate the minimum embedment depth for these two ground surface conditions (level and sloped ground) and these two subsurface conditions (clay and sand). However, since the walls are only loaded with water a maximum of 2 to 3 days, only the “Quick Case” (Total Stresses) was evaluated in CI Wall.

Since CI Wall assumes a horizontal ground surface in front of the wall, the strength parameters were reduced an amount such that the calculated passive earth pressure mimicked the expected reduced earth pressure associated with a sloping ground surface 5 feet from the face of the wall (essentially resulted in reducing the effective friction angle 6 degrees for a 3H:1V slope in front of the wall). See Figure 8-2 below for reference.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

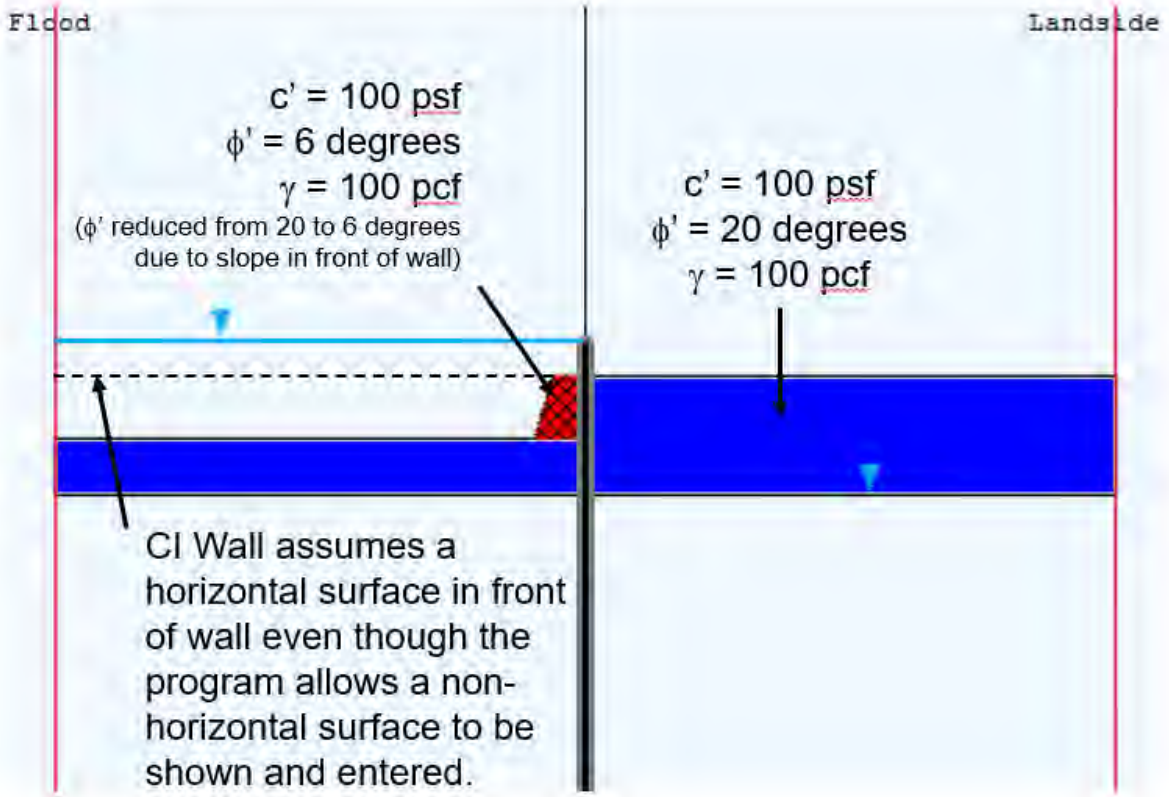

Figure 8-2: I-Wall Assumed Strength Parameters Reduced for Slope in Front of Wall

The structural engineer also checked embedment depths using CWALSHT. Refer to the Structural Appendix for CWALSHT calculations. The embedment depths calculated by CWALSHT were greater than those calculated using CI Wall, so the embedment depths for CWALSHT were used. The calculated embedment depths seem high for the stick-up height (3H on flat ground and 4H on sloped ground) and should be re-evaluated once actual subsurface and loading data is available during the design phase.

Based on the CWALSHT calculations, for a 6-foot wall stick-up height, the required depth of embedment was 18 feet for a horizontal ground surface (or 3H, which is greater than the required minimum of 10 feet or 2H, whichever was greater, provided in EM 1110-2-6066). For a 6-foot wall stick-up height, the required depth of embedment was 24 feet for a sloped ground surface (or 4H, which is greater than the required minimum of 10 feet or 2.5H, whichever was greater, provided in EM 1110-2-6066). The proposed I-wall configurations are shown in Figure 8-3.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

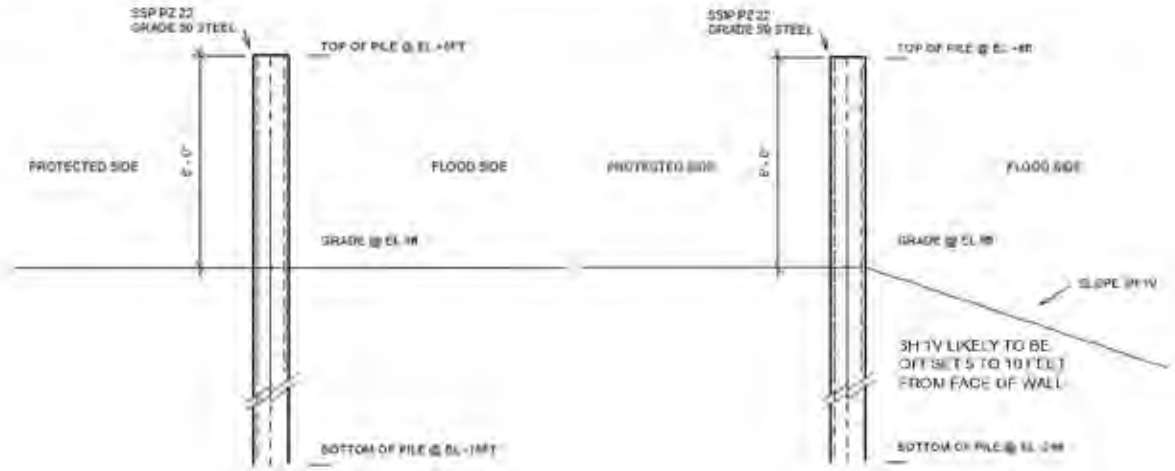

Figure 8-3: Proposed I-Wall Configurations

It is assumed that all sheet piles will be fitted with pointed driving shoes similar to that shown in Figure 8-4 to penetrate the boulders, hard layers, and other obstructions that are assumed to be present wherever I-walls are planned.

Figure 8-4: Example Sheet Pile Driving Shoe

No toe drains were assumed for the I-walls because of the flashy nature of the floodwaters. The water is only expected to be stored in the detention basins where I-walls are planned for a maximum of 2 to 3 days, which is not expected to be a sufficient period of time for seepage at the landside to develop given the expected fines content of the soil deposits (even the sand deposits).

8.2. L-Wall on Macropiles

L-walls were assumed when walls were located adjacent to the stream due to their enhanced stability against erosion as compared to I-walls, while I-walls were assumed when walls were used to create storage basins.

Macropiles, which are similar to micropiles in materials and installation methods but larger in diameter (micropiles typically are less than 12 inches in diameter), were selected over other foundation types, such as driven piles, drilled piers, stone columns, etc., for the following reasons:

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

1. Macropiles can provide both the necessary lateral and vertical capacity required and can be socketed into rock, coral, or dense layers to provide higher capacities, if necessary.
2. Macropiles are able to penetrate boulders, layers of coral or lava, and other obstructions with relative ease.
3. The installation process generally is less disruptive than other viable foundation systems (e.g., generally less noise and vibrations), which is an important consideration given the development and population density of the various measure sites.
4. Macropiles can be installed with smaller equipment, which is better able to accommodate the severe space limitations, including low overhead considerations.
5. Macropiles can be battered to increase lateral load capacity, if needed.
6. Cased macropiles increase lateral capacity and are better able to accommodate difficult soil/rock/drilling conditions.

For design purposes, the height of all walls was assumed to be 6 feet or less, except at the lower elevations of the Ala Wai Golf Course where 9-foot walls were planned. The base width of the L-wall was assumed to be 12 feet (6-foot) or 13 feet (9-foot) based on information provided by the structural engineer, while the base thickness was assumed to be 3 foot 4 inches (6-foot) or 3 foot 8 inches (9-foot). Refer to the Structural Appendix for information on the assumed wall design and configuration development.

Based on information provided by the structural engineer from an Ensoft Group analysis conducted by the structural engineer, the maximum vertical load (compression and uplift) on an individual macropile is expected to be on the order of 49 kips with the maximum lateral load on the order of 10 kips for 6-foot walls and 76 kips and 40 kips, respectively, for 9-foot walls. The calculated pile deflection was approximately 0.2 inch for the 6-foot walls and 0.8 inches for the 9-foot walls, both of which are within acceptable ranges.

Per Andrew Brengola in “Micropiles – Versatile Foundation Alternative for Challenging Projects” (Structure Magazine, 2005), “The lateral load capacity of vertical micropiles is generally between 5 and 15 tons; however, this resistance can be increased by battering the piles.” In other words, vertical (not battered) micropiles are capable of providing 10 to 30 kips laterally (5 to 15 tons), the low end of which is what is expected to be required for the predominant wall type for this project (6-foot walls). Furthermore, the capacity cited by Brengola is based on micropiles “generally less than 12 inches” whereas the piles for this project are 16 and 18 inches in diameter for 6-foot and 9-foot walls. As such, the lateral capacity will be greater than the 10 to 30 kips previously cited for smaller diameter micropiles; and it was concluded that macropiles are capable of providing the necessary lateral capacity for this project. Furthermore, for this project, the back row was assumed to be battered, which both reduces the expected deflection in the soft soils assumed to be present and increases the lateral capacity of the macropile. The Group analysis described previously also confirms the feasibility of achieving the required lateral capacity with the proposed macropile configuration.

Table 5-3 of the Micropile Design and Construction, Reference Manual (FHWA, 2005) was used to estimate the grout-to-ground ultimate bond strength used to calculate the uplift/compressive capacity of the macropiles. A copy of this table is provided in Figure 8-5. The compression and uplift capacities in macropiles are assumed to be the same. End-bearing was conservatively ignored for macropiles in compression. It was assumed “soft, medium plastic, silt and clay with some sand” was present along the full length of the macropile for this project, which is a

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

conservative assumption. The grout-to-ground ultimate bond strength for these types of soils is 5 to 10 psi for Type A micropiles (i.e., grout delivered under gravity instead of pressure) per Figure 8-5. The deposits likely will not be soft throughout the full length, such that the low end of 5 psi for grout-to-ground ultimate bond strength likely is a conservative assumption. In addition, sand layers, with an estimated grout-to-ground ultimate bond strength of 10 to 21 psi per Figure 8-5, also may be present, thereby further increasing the grout-to-ground ultimate bond strength. Since a casing will be used, grout likely will be delivered under pressure, which provides a higher upper bound on the grout-to-ground ultimate bond strength. According to the FHWA reference manual, use of the lower end of the values provided in Figure 8-5 is recommended when soft/loose or high plasticity deposits are expected, which they are for this project.

Soil / Rock Description	Grout-to-Ground Bond Ultimate Strengths, kPa (psi)			
	Type A	Type B	Type C	Type D
Silt & Clay (some sand) (soft, medium plastic)	35-70 (5-10)	35-95 (5-14)	50-120 (5-17.5)	50-145 (5-21)
Silt & Clay (some sand) (stiff, dense to very dense)	50-120 (5-17.5)	70-190 (10-27.5)	95-190 (14-27.5)	95-190 (14-27.5)
Sand (some silt) (fine, loose-medium dense)	70-145 (10-21)	70-190 (10-27.5)	95-190 (14-27.5)	95- 240 (14-35)
Sand (some silt, gravel) (fine-coarse, med.-very dense)	95-215 (14-31)	120-360 (17.5-52)	145-360 (21-52)	145-385 (21-56)
Gravel (some sand) (medium-very dense)	95-265 (14-38.5)	120-360 (17.5-52)	145-360 (21-52)	145-385 (21-56)
Glacial Till (silt, sand, gravel) (medium-very dense, cemented)	95-190 (14-27.5)	95-310 (14-45)	120-310 (17.5-45)	120-335 (17.5-48.5)
Soft Shales (fresh-moderate fracturing, little to no weathering)	205-550 (30-80)	N/A	N/A	N/A
Slates and Hard Shales (fresh-moderate fracturing, little to no weathering)	515-1,380 (75-200)	N/A	N/A	N/A
Limestone (fresh-moderate fracturing, little to no weathering)	1,035-2,070 (150-300)	N/A	N/A	N/A
Sandstone (fresh-moderate fracturing, little to no weathering)	520-1,725 (75.5-250)	N/A	N/A	N/A
Granite and Basalt (fresh-moderate fracturing, little to no weathering)	1,380-4,200 (200-609)	N/A	N/A	N/A

Type A: Gravity grout only
Type B: Pressure grouted through the casing during casing withdrawal
Type C: Primary grout placed under gravity head, then one phase of secondary "global" pressure grouting
Type D: Primary grout placed under gravity head, then one or more phases of secondary "global" pressure grouting

Figure 8-5: Typical Micropile Grout-to-Ground Bond Strengths (FHWA, 2005)

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Using a grout-to-ground ultimate bond strength of 5 psi, a diameter of 16 inches (14-inch diameter casing plus 1 inch of cover), a length of 40 feet, and a factor of safety of 2, the calculated allowable capacity in compression and uplift is 60 kips (= PI * 16 in * 40 ft * 12 in/ft * 5 psi / 1000 lbs/kips / FS of 2 = 60 kips), which is greater than the 49 kips expected to be needed, for the 6-foot walls. Using a similar approach, the calculated allowable capacity in compression and uplift is 85 kips for an 18-inch diameter macropile 50 feet long, which is greater than the 76 kips expected to be needed, for the 9-foot walls. No reduction was applied to the capacity due to group effects since the macropiles are spaced at least three diameters apart. Refer to Figure 8-6 for capacity calculations for various macropile diameters at selected lengths. This figure shows that a 12 to 14-inch macropile 40 feet long should be capable of providing the required 49 kips required for 6-foot walls. However, a 16-inch macropile is assumed because of concerns about lateral deflections of smaller diameter macropiles/micropiles given the lack of sufficient soil data and the known presence of soft and loose surface soils. A similar process was used when selecting an 18-inch macropile for the 9-foot walls.

Diameter (in)	Pile Length (ft)	Minimum Grout-to-Ground Bond Ultimate Strength (psi)	Maximum Grout-to-Ground Bond Ultimate Strength (psi)[1]	Minimum Ultimate Vertical Capacity (kips)	Maximum Ultimate Vertical Capacity (kips)	Factor of Safety	Minimum Allowable Vertical Capacity (kips)[2]	Maximum Allowable Vertical Capacity (kips)
12	40	5	7.5	90	136	2	45	68
14	40	5	7.5	106	158	2	53	79
16	40	5	7.5	121	181	2	60	90
18	40	5	7.5	136	204	2	68	102
12	50	5	7.5	113	170	2	57	85
14	50	5	7.5	132	198	2	66	99
16	50	5	7.5	151	226	2	75	113
18	50	5	7.5	170	254	2	85	127

1 - Maximum values were limited to no greater than the average value for the bond strength (i.e., the middle of reported range of 5-10 psi in FHWA table) due to unknowns associated with the soils.
2 - Lower bound values were considered most likely due to loose granular materials and medium to high plasticity cohesive materials

Figure 8-6: Allowable Compressive/Uplift Capacity for Macropiles

The macropile for this project was assumed to be a cased macropile. Specifically, the macropiles were assumed to be 40 feet long and 16 inches in diameter with a 14-inch outer diameter X ½-inch thick full-length permanent casing and a full-length No. 11 all-thread center bar for 6-foot walls and 50 feet long and 18 inches in diameter with a 16-inch outer diameter X ½-inch thick full-length permanent casing and a full-length No. 11 all-thread center bar for 9-foot walls. The macropiles were assumed to be in two rows with 5-foot on-center spacing, with the first row vertical and the second row battered at 3V:1H. All reinforcing steel was assumed to be stainless steel or epoxy coated since the macropiles are a permanent installation. It was assumed that the bending resistance in the pile created by the lateral loading can be accommodated by the 14-inch to 16-inch permanent full-length casing. For budgetary purposes (and due to deflection concerns), it was assumed that the back row of macropiles will be installed at a batter of 6V:1H while the front row will be vertical. The general proposed configuration of the 6-foot and 9-foot L-walls is provided in Figure 8-7 and Figure 8-8, respectively.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

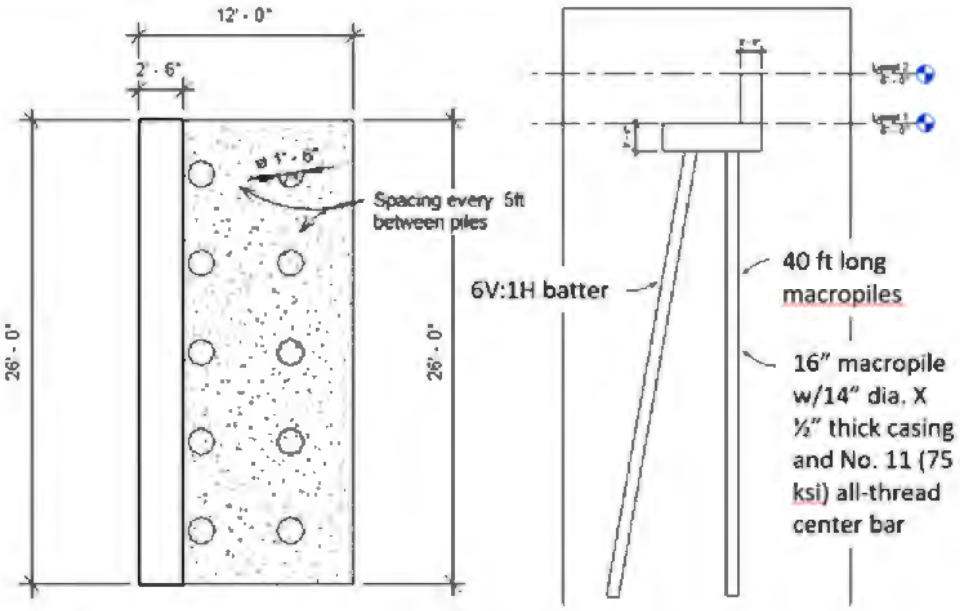

Figure 8-7: Proposed 6-Foot L-Wall Layout

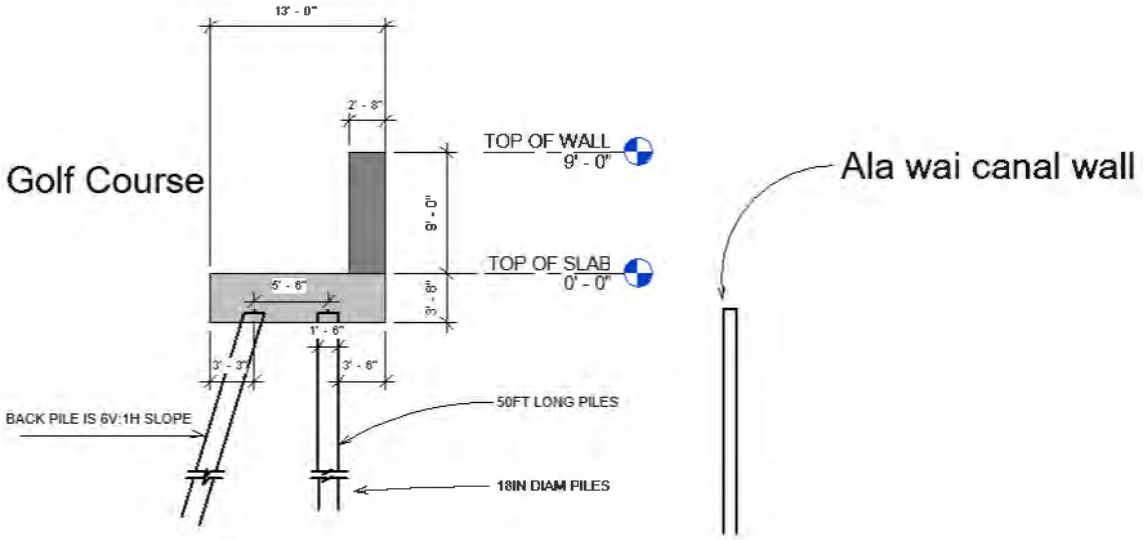

Figure 8-8: Proposed 9-Foot L-Wall Layout

The macropile design developed for this project was compared to the micropiles piles developed for an L-wall design associated with the Ala Wai Canal Wall Repair (Geolabs, 2017) for reasonableness. The micropiles for that project were assumed to consist of a cased micropile system as described below:

> Based on the subsurface conditions encountered at the project site, we recommend using a cased micropile system with a grout bulb diameter of at least 7 inches to support the new retaining wall. The micropiles should be spaced at 3 feet on-centers or greater. The permanent casing for the cased micropile system should have an inside diameter (ID) of at least 7 inches. The minimum thickness of the permanent casing should be about 0.375 inches. A reinforcing steel bar consisting of a Grade 75 No. 11 all-thread reinforcing bar with a cross-sectional area of 1.56 square inches may be considered.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Since the micropiles are used in a permanent application, epoxy coated or stainless steel bars should be used.

In general, while the Geolabs L-wall and the L-wall for this project were for different purposes and have different loading, the expected magnitude of the loading was assumed to be similar. The Geolabs micropile was designed for a 7-foot-tall retaining wall on the canal retaining earthen backfill while most of the L-walls for this project will retain only water and be limited to 6 feet tall. The water only loading should create less demand on the wall as compared to a combination of soil and water. A larger diameter “micropile” (or macropile) for this project was deemed reasonable due to the many unknowns associated with subsurface conditions and because the spacing was increased to 5 feet on-center from 3 feet on-center. The casing wall thickness was increased to provide higher moment capacity and a stiffer element to help deflection. A higher number of smaller-diameter macropiles were assumed to be similar in costs than fewer larger-diameter macropiles based on discussion with the cost estimator.

No sheet piles were assumed to be necessary below L-walls given the transient nature of expected floodwaters. Based on information provided by the H&H engineer, floodwaters generally are up and down in approximately 3 to 4 hours on all the streams and approximately 10 to 12 hours on the Ala Wai Canal, likely an insufficient time to develop seepage at the landside.

Additional subsurface information and development of actual loads will be necessary to better refine the assumed design provided above.

8.3. J-Wall on Macropiles

J-walls were assumed where visual connection with the Ala Wai Canal needed to be maintained for pedestrians (i.e., along the Ala Wai Canal). Other configurations, such a levee/I-wall configuration or a backfilled I-wall, were considered. However, the team selected the J-wall primarily due to concerns about imparting new loading on the existing sensitive, historic canal walls either through creating surcharge loading from the levee or lateral deflection from the sheet pile associated with I-walls. The existing canal walls reportedly already show signs of tilting and settlement under current conditions. In addition, there were vibration concerns associated with the installation of the sheet pile, unless a more expensive hydraulic push method is used. Replacement of the existing canal walls was deemed unacceptable due to the historic significance of the walls, the reported environmental contamination of the canal, and the ownership of the walls (i.e., anything inside the existing canal walls reportedly was owned and operated by an entity other than the planned Sponsor, which created project complications).

For the purposes of this report, the J-wall was assumed to have the same design as the L-wall, with the same wall thickness, foundation width, and macropiles configuration. The general assumed configuration of the J-wall is provided in Figure 8-9. The only difference between the J-wall and the L-wall is the addition of a 3-foot concrete wall on the heel (landside) of the foundation to create an elevated platform for construction of a sidewalk. The purpose of the rear wall and backfill would be to effectively convert the 6-foot floodwall on the waterside to a 3-foot wall so that pedestrians along the Ala Wai Canal can maintain visual connection with the canal (in addition to not being “trapped” on the waterside of the wall until the next closure). It is assumed that drainage for the sidewalk backfill will be provided.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

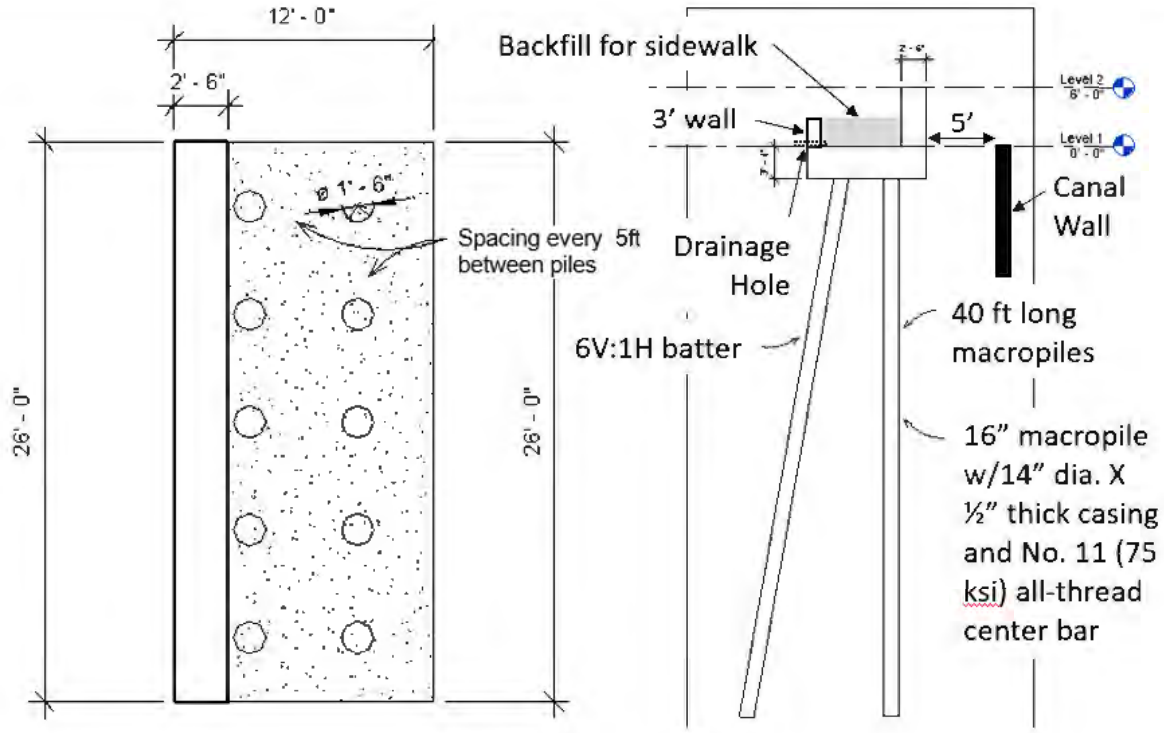

Figure 8-9: Proposed J-Wall Layout

8.4. U-Wall on Macropiles

A U-wall (i.e., two L-walls facing one another) was assumed along Makiki from the Ala Wai Canal to Fern Street. The Makiki Floodwall was eliminated from the TSP due to induced damages.

The U-wall was assumed to be similar to two L-walls (as described in Section 8.2) facing each other, with the exception of the following changes: base thickness reduced from 40 inches to 30 inches; the base width varied to match the existing channel width; and all macropiles vertical (no batter). The wall will be constructed within the walls of the existing drainage channel with the new wall bottom matching the existing drainage channel bottom. The new wall will extend 6 feet above the existing canal walls/surrounding ground surface. The area between the existing and new concrete walls will be backfilled (concrete assumed for budgetary purposes). The general concept of the proposed U-wall is shown in Figure 8-10.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

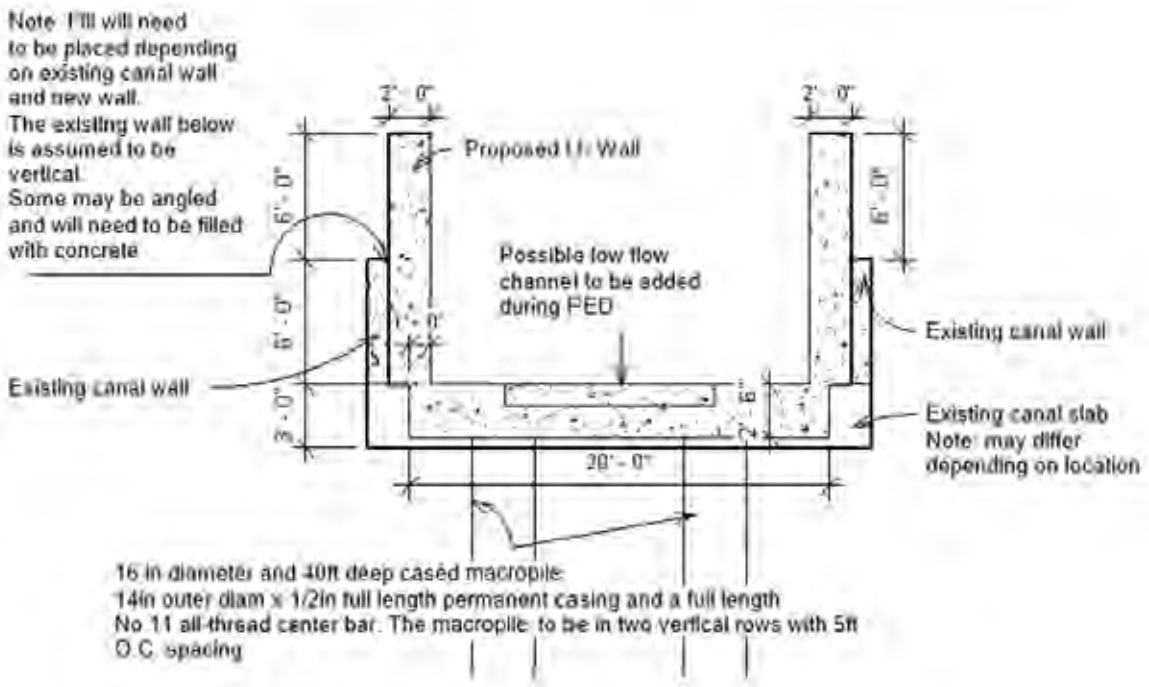

Figure 8-10: Proposed U-Wall Layout

The proposed wall design assumes that all the existing walls are similar to the limited as-built drawings provided for review by the City of Honolulu, which show rubble masonry walls with a concrete bottom as shown in Figure 8-10. This assumption will need to be confirmed during design. A concrete bottom may not be present in all locations. Where not present, stabilization of the creek channel bottom with granular fill to facilitate construction may be necessary. In addition, a condition survey of the existing walls and bottom should be conducted during the design phase to help inform construction and the length of existing wall that be exposed at one time.

To maintain the integrity of the support for the construction adjacent to the canal provided by the existing walls, the new construction will have to be constructed in stages with only short sections constructed at one time, with construction on adjacent panels delayed until support is restored at the excavated panel. As an example, the bottom slab for the new wall could be excavated in 10-foot sections, with no more than one 10-foot section excavated in a 50-foot section. Slabs could be constructed in a “leapfrog” fashion until a continuous new bottom is constructed. Having to limit construction to short stretches will increase construction costs and require additional time.

It is assumed that the macropiles would be installed through the existing concrete slab, where present, possibly by pre-coring through the slab. A sonotube, or other bond break mechanism, would have to be placed between the existing slab and macropile (to facilitate future demolition of the existing slab).

8.5. Tieback I-Walls

Due to access constraints (specifically insufficient distance between the existing streambank and the existing structures for construction of the planned L-wall), the planned L-wall along the

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

west bank of the Manoa-Palolo Stream from Date Street to Kapiolani Boulevard was converted to a tieback I-wall for the TSP. The location of this wall is shown in Figure 8-11. Figure 8-11 shows the close proximity of the existing structures.

Figure 8-11: Location of Tieback I-Wall

The general assumed concept of the planned tieback I-wall is depicted in in Figure 8-12. The details for this wall were developed based on general past experience with similar wall types, with the general reasonableness confirmed with preliminary calculations by the structural engineer. Refer to the Structural Appendix for preliminary calculations conducted for this wall. For the purposes of this report, the I-wall was assumed to be a PZ30 sheet pile that would be toed into rock (rock exposed in some locations along the stream) or would extend 15 feet below the bottom of the stream. The bottom of the sheet pile must be capable of providing lateral resistance and must be “restrained” by toeing into the rock or penetration below the stream bottom (i.e., to achieve restraint through cantilevering action). The tieback would serve to anchor the top of the sheet pile. In addition, the existing sloped streambank also would provide lateral resistance (confinement) for the sheet pile. However, due to the steep nature of that slope, it was assumed that the lateral resistance provided by the steep streambank would be insufficient and use of an anchor would be required. For budgetary purposes, tiebacks were assumed to be located 6 feet below the crest of the streambank, 50 feet long, and 7 feet on-center with an HP12X53 continuous waler.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

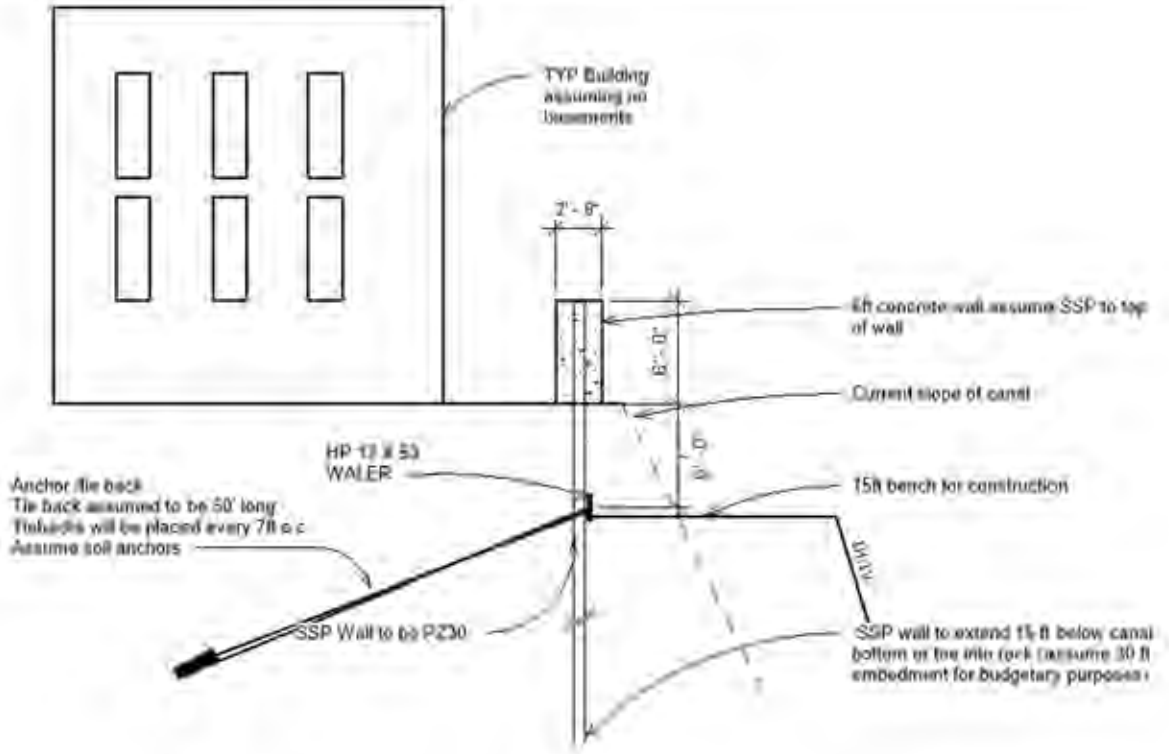

Figure 8-12: Proposed Tieback I-Wall Layout

Due to the extremely close proximity of the existing structures, it was assumed that the sheet piles would be installed using the press-in method, similar to the Giken Method. The press-in method involves equipment that hydraulically pushes the sheet pile into the ground, instead of driving the sheet pile, thereby significantly reducing the vibrations concerns associated with driving sheet pile. In addition, this method is specifically designed for tight access locations, with the sheet pile installer riding along installed sheet piles, such that existing structures can be as little as 5 feet away. Furthermore, this sheet pile can be advanced into rock (toed into rock) using the auger advancer, which reportedly is capable of penetrating hard rock.

A bench constructed in the stream will be required for the tieback installation. For planning purposes, it is assumed this bench will be 15 feet wide and constructed of rock, with the rock sloped 1H:1V into the stream. It is assumed that this bench would serve dual purposes: first as a bench for installation of the anchor and second as a bench to facilitate construction of the sheet pile wall (e.g., placement of the power pack associated with the press-in method). Preliminary plans include using a crane situated across the stream to provide the sheet pile for installation (Figure 8-13). It may be possible for this work to be staged from the bench to eliminate the crane. However, the bench may have to be wider to achieve this. These details regarding construction will be further developed during the design phase.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

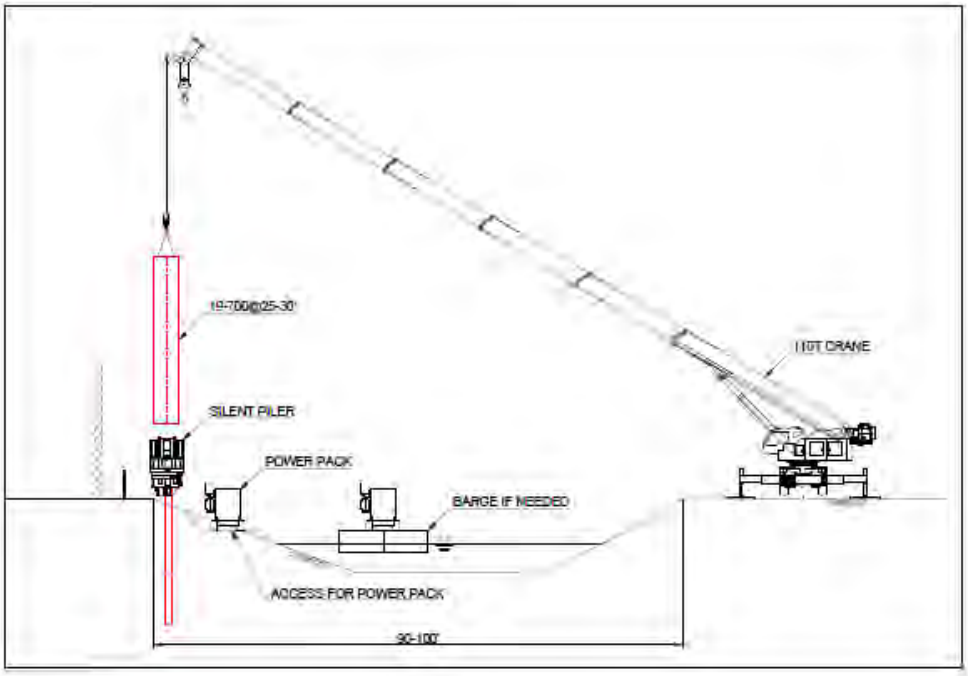

Figure 8-13: Preliminary Installation Process

There were concerns that the planned sheet pile may impede the flow of possible shallow groundwater in the area. Borings that will be advanced during the design phase will help better determine how much of a concern groundwater may be in this area. It is noted that no widespread groundwater was observed to be seeping into the stream from the banks. However, localized seeps were observed. It is assumed that the groundwater concerns can be addressed during design by designing the wall for hydrostatic pressures, providing a drainage system directly behind the wall for some depth below the existing ground surface (say 5 feet), or providing drainage through the sheet pile wall where known seeps are identified.

8.6. Levee

As with the walls, the levees were limited to heights of 6 feet, except at the lower elevations of the Ala Wai Golf Course where 9-foot levees were planned. Per EM 1110-2-1913, Section 6-2 (USACE, 2000), the minimum levee section shall have a crown width of at least 10 feet and a side slope flatter than or equal to 2H:1V. EM 1110-2-1913 is in the process of being updated. According to the draft version of EM 1110-2-1913 (USACE, 2022b), minimum crown widths of 10 to 12 feet are commonly used, depending primarily on roadway requirements and potential emergency response. Where there is a need to drive on the levee crown during flood events (expected to the case for this project), a minimum 12-foot crown width is recommended. Side slopes flatter than or equal to 2H:1V are accepted as the steepest slopes that can be easily constructed while ensuring stability of any riprap layers, while side slopes of 3H:1V are considered the steepest slopes that can be traversed by mowing equipment.

For the purposes of this project, side slopes were assumed to be 3H:1V, which generally is considered a “safe” side slope for the vast majority of subsurface conditions for shorter levees, especially when the water is not expected to be on the levee for extended periods (2 to 3 days at most) and the levees are limited to maximum heights of 6 to 9 feet. A typical proposed levee

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

cross-section is provided in Figure 8-14. In addition, the natural slopes along streambanks in the project vicinity, many of which are well in excess of 6 to 9 feet high, are much steeper than 3H:1V, so it is expected that a slope of 3H:1V comprised of compacted fill will be similarly stable. For this project, having maintainable grass slopes (i.e., 3H:1V or flatter) was considered desirable. A minimum crown width of 12 feet was assumed for vehicle access.

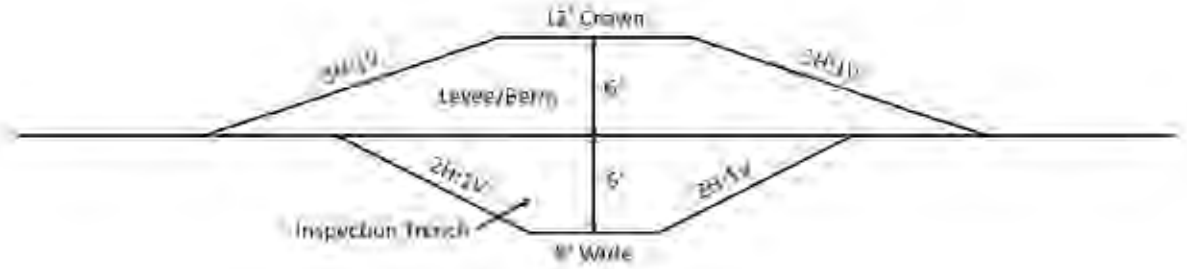

Figure 8-14: Typical Levee Cross-Section

Due to space constraints, the use of levees is expected to be limited to the Ala Wai Golf Course. Settlement estimates for existing soils were provided in the geotechnical reports for two nearby projects. According to the Foundation Investigation for the Kaimuki High School Auditorium (Hardin-Lawson Associates, 1976), 8 inches of settlement was projected for 6 feet of areal fill. According to the Subsurface Investigation Report for the Ala Wai Maintenance Facility at the Ala Wai Golf Course (Fewell Geotechnical Engineering, 1993), 3 inches of settlement would be expected for 6 feet of areal fill. Due to the lack of boring coverage for this project, the foundation soils conservatively were assumed to settle 8 inches under the weight of the planned 6-foot levee. According to EM 1110-2-1913, Section 6-9 (USACE, 2000), common allowances for settlement of compacted fill are 0 to 5 percent. Assuming 5 percent consolidation of new fill, the estimated settlement of the compacted levee is 4 to 5 inches (= 0.05 * 6 to 9 feet * 12 inches/feet = 3.6 to 5.4 inches, say 4 to 5 inches). As a result, the total overbuild for a 6 to 9-foot levee was assumed to be on the order of 12 inches (8 inches in the foundation soils and 4 to 5 inches in the new fill).

The levee will include an inspection trench to expose or intercept any undesirable near-surface foundation features such as old drain tile, active or abandoned water or sewer lines or other utilities, animal burrows, buried logs, pockets of unsuitable material, or other debris. Inspection of the exploration trench also allows the design engineers to assess the near-surface foundation conditions directly beneath the levee. For the purposes of this report, the inspection trench will be 6 feet deep and 8 feet wide with assumed 2H:1V side slopes. The side slopes were flattened to 2H:1V due to soft soils and shallow groundwater concerns. Due to shallow groundwater and the limited height of the levee, consideration can be given to reducing the inspection trench depth to 3 feet and flatten the cut side slopes from 2H:1V to 1H:1V once soil borings are conducted and the groundwater and upper soil conditions are better understood.

No toe drains were assumed for the levees because of the flashy nature of the floodwaters. The water is only expected to be stored in the detention basins for a maximum of 2 to 3 days.

8.7. Detention Basin

Detention basin sizes and depths were determined based on the hydraulic needs of the system and the available land. Detention basin sidewalls were assumed to be 3H:1V, which generally is

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

considered a “safe” side slope for the vast majority of subsurface conditions. No analysis was conducted. The natural slopes along streambanks in the project vicinity, many of which are well in excess of 6 feet high, are much steeper than 3H:1V, so it is expected that a slope of 3H:1V comprised of compacted fill will be similarly stable. It is noted that no detention basins were included in the TSP.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

9. Individual Measures

This section includes a brief description of the general site conditions, the geology, the assumed subsurface conditions, and any additional comments for the individual measures, beyond the geotechnical concerns identified in Section 7.

No recommendations were developed for the closure structures at roadway crossings or the inlet/outlet drainage structures associated with the individual measures, since the details of these structure types reportedly were not necessary for the purposes of this feasibility study. Instead, the cost estimator indicated that a lump sum typically was assigned for the costs of these structures and only a physical count of the structures was necessary.

The summaries on the individual measures provided below were developed during the alternative array evaluation. As a result, the alignments shown are for the alternative array evaluation, not the TSP evaluation. However, the alignment differences between the alternative array evaluation and the TSP are not significantly different and do not have any significant impact on the information included in the following sections. Refer to Section 4 for the proposed layouts for the TSP. In addition, summaries for all measures in the 3 alternative arrays considered, not just those in the TSP, are included below.

9.1. Kanaha Floodwall

9.1.1. General Description

The Kanaha Floodwall tentatively will consist of an L-wall founded on macropiles. The floodwall will be located on the south side of the existing Kanaha Stream. The floodwall is located in a heavily populated area. Existing development, including single-family homes, multi-family homes, and high-rise buildings, is located immediately on either side of the stream. Refer to Figure 9-1 for typical examples of the existing conditions at selected locations along the stream (wall to be located on left side of stream/ditch shown in photos). The existing ditch bottom and walls are lined, typically with concrete along the bottom and mortared lava rock/concrete rubble masonry (also referred to as CRM) walls.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Figure 9-1: Existing Kanaha Ditch at Selected Intersections

9.1.2. Geology

According to the geologic map, the Kanaha Floodwall is underlain both by Tuff (eastern 740 feet) and (Holocene) Alluvium (remaining 1,460 feet) as shown in Figure 9-2.

Figure 9-2: Kanaha Floodwall Mapped Geology

According to the geologic map, the Alluvium is comprised of unconsolidated deposits of silt, sand, and gravel along streams and in valley bottoms. In some areas, the Alluvium grades

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

upslope to talus and colluvium. Where information is lacking, Alluvium may include deposits more appropriately assigned to older alluvium by virtue of greater consolidation or topographic settings not at grade with modern drainages.

According to the geologic map, the Tuff is bedded black cindery ash and lapilli (rock fragments from 2 to 64 mm in diameter (0.1 to 2.5 inches) ejected from a volcano) ejected during strombolian eruptions. Tuff blankets large areas southwest of vents, likely owing to the position of vents on high ridges and subsequent deflection of eruptive plume by trade winds.

The primary difference between these two formations is that the alluvial deposits are unconsolidated (soft, compressible, poor quality) while the (weathered) tuff deposits typically are better quality and likely suitable for developing much higher macropile capacities over shorter lengths.

9.1.3. Assumed Subsurface Conditions

There was no soil boring information in the immediate vicinity of the Kanaha Floodwall. As a result, subsurface information from nearby borings and wells in similar geologic formations was used to inform the assumed subsurface conditions at the site. The nearby borings and wells used to develop the assumed subsurface conditions are shown in Figure 9-3. These sources were on the order of 0.2 to 0.5 mile away from the site. Since there were no “nearby” borings in the Alluvium, borings from the Kaimuki High School Auditorium, generally on order of 1.6 miles southeast of the planned Kanaha Floodwall, were used to inform the general conditions in the Alluvium.

Figure 9-3: Kanaha Floodwall Nearby Borings & Wells

The assumed subsurface conditions for this site were predominantly based on the subsurface information encountered in the nearest wells (1883 Liholio Street and 1899 Nehoa Street);

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

however, the alluvial deposits were assumed to be thicker as the distance away from the contact between the Tuff and Alluvium increased.

For planning and budgeting purposes for the portion of the floodwall mapped in the Tuff (740 feet), 15 to 25 feet of compressible deposits (Alluvium) overlying 30 to 55 feet of cinders (Tuff) was assumed. For the portion of the floodwall mapped in the Alluvium (1,460 feet), 25 to 40 feet of compressible deposits (Alluvium) overlying cinders (Tuff) was assumed. The Alluvium was assumed to be comprised of generally soft to loose, compressible soil deposits, while the cinders were assumed to be dense (difficult drilling to rock drilling) based on information contained within the Preliminary Soil Investigation for the Makiki Cliffs Condominium Proposed Forty-Story Highrise on Green Street (H. Patel, 1974). These borings were designed as the "Green & Ernst" borings for this project.

Groundwater was assumed to be below expected mass excavation depths for the L-wall, but above the tip of the planned macropiles. However, trapped water may be encountered in the soils behind the existing retaining walls lining the ditch.

9.1.4. Additional Comments

The wall must be designed to minimize lateral load transfer to the existing walls. In general, the direction of loading was expected to be away from the exposed height of the existing walls. In addition, macropiles were battered to help reduce lateral movement of the proposed wall.

The wall will be located as close as possible to the existing ditch to minimize land acquisition and disruption to the existing property owners. However, the cost estimate should account for the inefficiency created by the tight access considerations. For example, macropiles likely will have to be installed in batches, instead of all at one time, because once the macropiles are installed access to wall areas past the recently installed macropiles will be difficult (i.e., wall to occupy 12 feet of the 12 to 15-foot access path so it not possible to drive over area once macropiles are installed). In other words, the macropile contractor will do their work for a section followed by the concrete contractor, with this process repeating until the entire wall length is completed. This limitation will create higher costs, requiring multiple mobilizations and an extended construction schedule for the different construction crews (e.g., the macropile and concrete contractors). Alternatively, instead of staggering the construction schedule, consideration could be given to installing all the macropiles but temporarily backfilling around the macropiles to create an access road above them, with the temporary backfill re-excavated with the remaining wall construction.

9.2. Makiki District Park Detention

9.2.1. General Description

The Makiki District Park detention basin tentatively will consist of a 6- to 10-foot-deep detention basin with 3H:1V side slopes and 6-foot tall I-wall around the basin perimeter. The detention basin is located in a very gently sloping (5 to 7 feet of fall over approximately 500 feet), open grass field of Makiki District Park. The existing conditions, along with the planned detention basin, are shown in Figure 9-4.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Figure 9-4: Makiki District Park Existing Conditions

9.2.2. Geology

According to the geologic map, the Makiki District Park detention basin is underlain by (Holocene) Alluvium as shown in Figure 9-5. The Alluvium is comprised of unconsolidated deposits of silt, sand, and gravel along streams and in valley bottoms. In some areas, the Alluvium grades upslope to talus and colluvium. Where information is lacking, Alluvium may include deposits more appropriately assigned to older alluvium by virtue of greater consolidation or topographic settings not at grade with modern drainages.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Figure 9-5: Makiki District Park Detention Mapped Geology

9.2.3. Assumed Subsurface Conditions

There was no soil boring information in the vicinity of the Makiki District Park Detention. As a result, the assumed subsurface conditions were based on information from nearby wells to determine the assumed general layering. The nearby wells used to develop the assumed subsurface conditions are shown in Figure 9-6. These sources were on the order of 0.2 to 0.3 mile away from the site. Since there were no “nearby” borings in the Alluvium, borings from the Kaimuki High School Auditorium, generally on order of 1.7 miles southeast of the planned Makiki District Park Detention, were used to inform the general conditions in the Alluvium.

Figure 9-6: Makiki District Park Nearby Borings & Wells

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

The assumed subsurface conditions for this site were predominantly based on the subsurface information encountered in the nearest wells (1883 Liholio Street, 1899 Nehoa Street, and 1938 Berentania and Keeaumoku Street as shown in Figure 9-6); however, the alluvial deposits were assumed to be thicker as the distance away from the contact between the Tuff and Alluvium increased.

Alluvial-type deposits were encountered in the upper 16 to 25 feet of the three nearest wells. The alluvial-type deposits were underlain by “black sand” or “cinders”, which was interpreted to be the Tuff described in Section 9.1.2. The black sand/cinders varied from 30 to 55 feet thick in the two northernmost wells (Liholio and Nehoa) and thinned to 5 feet thick in the southernmost well (St. Berentania). The cinders in the southernmost well were underlain by 5 feet of coral, which was underlain by 5 feet of black rock, which was underlain by 17 feet of coral. It is noted that all 3 wells were located in the mapped Tuff or near the mapped Tuff/Alluvium interface. Since the site was located further away from the interface between the two different geologic formations and appeared to be located along the general alignment of the old alluvial stream flow, the depth of alluvial deposits was assumed to be thicker than indicated in the wells.

For planning and budgeting purposes, the Alluvium was assumed to be on the order of at least 25 to 30 feet thick. The Alluvium was assumed to be comprised of generally soft to loose, compressible soil deposits that can be penetrated by the sheet pile provided the sheet pile tip is properly accessorized with a driving shoe to penetrate boulders or other obstructions in the Alluvium.

Groundwater was assumed to be below expected mass excavation depths of 6 to 10 feet planned for the detention basin.

9.2.4. Additional Comments

The Alluvium was assumed to have sufficient depth to permit the driving of sheet piles for the planned I-wall embedment of 24 feet. If the Tuff is encountered at shallower depths than assumed, issues with driving may be encountered. Confirming the depth of the Tuff will be critical during future studies to confirm the viability of the assumed wall configuration. If Tuff is encountered at shallower depths, a macropile-supported L-wall may be more appropriate for the subsurface conditions.

It was assumed cut slopes in the Alluvium will be stable on 3H:1V since slopes steeper than the planned cut slopes were observed in these deposits elsewhere within the city.

It was assumed the I-wall will be set back off the cut slope at least 5 to 10 feet to alleviate the potential loading of the slope resulting from passive pressures below the point of rotation of the embedded sheet pile.

9.3. Manoa Valley District Park Detention

9.3.1. General Description

The Manoa Valley District Park detention basin tentatively will consist of detention basin that will include 6- to 8-foot-deep cuts at the high (north) end of the site and 6-foot I-walls at the low (south) end of the site. The detention basin is located in the area of 4 playing fields that gently

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

slope to the south (15 feet of fall over approximately 850 feet) at Manoa Valley District Park. The existing conditions, along with the planned detention area, are shown in Figure 9-7.

Figure 9-7: Manoa Valley District Park Existing Conditions

9.3.2. Geology

According to the geologic map, the Manoa Valley District Park Detention is underlain by (Holocene) Alluvium as shown in Figure 9-8. According to the geologic map, the Alluvium is comprised of unconsolidated deposits of silt, sand, and gravel along streams and in valley bottoms. In some areas, the Alluvium grades upslope to talus and colluvium. Where information is lacking, Alluvium may include deposits more appropriately assigned to older alluvium by virtue of greater consolidation or topographic settings not at grade with modern drainages.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Figure 9-8: Manoa Valley District Park Detention Mapped Geology

9.3.3. Assumed Subsurface Conditions

There was no soil boring or well information in the vicinity of the Manoa Valley District Park Detention located within the same geologic formation as the site (Figure 9-9). The nearest borings (0.2 to 0.6 mile) and wells (1.2 miles) were located in different geologic formations, such that the conditions encountered at those locations were not considered similar to the site. The closest borings in the same geologic formation as the site were those associated with the Kaimuki High School Auditorium, which was located 1.9 miles south-southwest of the site. As a result, borings from the Kaimuki High School Auditorium were used to inform the general conditions in the Alluvium.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Figure 9-9: Manoa Valley District Park Nearby Borings & Wells

For planning and budgeting purposes, the Alluvium was assumed to be deep enough (greater than 50 feet) to control the design of the flood reduction measures. The Alluvium was assumed to be comprised of generally soft to loose, compressible soil deposits that can be penetrated by the sheet pile provided the sheet pile tip is properly accessorized with a driving shoe to penetrate boulders or other obstructions in the Alluvium.

Groundwater was assumed to be sufficiently below expected mass excavation depths of 6 to 8 feet planned for the detention basin to not impact the planned construction.

9.3.4. Additional Comments

It was assumed cut slopes in the Alluvium will be stable on 3H:1V since slopes steeper than the planned cut slopes were observed in these deposits elsewhere within the city.

It was assumed that the ground will be sufficiently flat around the I-wall locations, such that assuming a horizontal, not sloped, ground surface was reasonable.

9.4. Woodlawn Drive Floodwall

9.4.1. General Description

The Woodlawn Drive Floodwall tentatively will consist of a 6-foot-tall L-wall founded on macropiles. The floodwall is located on the west side of Manoa Stream. The floodwall to the north of Woodlawn Bridge is located in a grass area adjacent to a shopping center parking lot. The floodwall to the south of Woodlawn Bridge is located on University of Hawaii property for greenhouses and other agricultural activities. The existing conditions are shown in Figure 9-10. Views from Woodlawn Bridge looking upstream and downstream are shown in Figure 9-11.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Figure 9-10: Woodlawn Drive Floodwall

Figure 9-11: Looking Upstream (Top) and Downstream (Bottom) from Woodlawn Drive Floodwall

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

9.4.2. Geology

According to the geologic map, the Woodlawn Drive Floodwall is underlain by two different types of lava flows as shown in Figure 9-12. However, as shown in Figure 9-12, both Holocene Alluvium and Older Alluvium are mapped in very close proximity to the proposed floodwall. Overburden soils at the floodwall appeared to be comprised of (Holocene or Older) Alluvium, instead of soils weathered from the lava flows, based on nearby borings. However, the rock formations that underlie the Alluvium appear to be related to the lava flows.

Figure 9-12: Woodlawn Drive Floodwall Geology

According to the geologic map, the lava flows associated with the Ko'olau Basalt (versus deposits from the Tantalus Peak and Sugar Loaf vents) are mapped on the southern three-quarters of the floodwall. These deposits are comprised of ʻaʻā (60 percent) and pāhoehoe, which is thought to be more abundant near the crest of the Koʻolau Range.

The lava flows from the Tantalus Peak and Sugar Loaf vents are mapped on the northern one-quarter of the floodwall. No additional description of these geologic deposits was provided on the geologic map.

The Older Alluvium is comprised of consolidated sand and gravel, some of it sufficiently lithified to warrant the designation "conglomerate." It is chiefly well rounded and moderately sorted, but includes minor, poorly sorted colluvial deposits. It forms terrace deposits and thick valley fills now being incised by modern drainages.

The (Holocene) Alluvium is comprised of unconsolidated deposits of silt, sand, and gravel along streams and in valley bottoms. In some areas, the Alluvium grades upslope to talus and colluvium. Where information is lacking, Alluvium may include deposits more appropriately assigned to older alluvium by virtue of greater consolidation or topographic settings not at grade with modern drainages.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

9.4.3. Assumed Subsurface Conditions

Soil test borings from two nearby projects were located in the immediate vicinity of the northern half of the floodwall, while no soil test borings or water wells were located near the southern half of the floodwall. The two nearby projects were the Manoa Marketplace Foundation Investigation (Dames & Moore, 1973) and the Manoa Stream Improvements Soils Investigation (Hirata & Associates, 2016b). Refer to Figure 9-13 for the location of these nearby borings. The subsurface information from these nearby borings was used to inform the assumed subsurface conditions for the proposed floodwall.

Figure 9-13: Woodlawn Drive Floodwall Nearby Borings & Wells

In the Manoa Stream Improvement borings (B-series in Figure 9-13), the surface soils were classified as stiff to medium stiff, dark brown to grayish brown clayey silt, extending to depths ranging from about 7.5 to 12.5 feet. Firm conditions were encountered at deeper sections in two borings (B1 and B4). Underlying the clayey silt were dense to medium dense granular soils consisting of mottled brown silty gravel and dark brown to grayish brown silty sand, extending to the maximum depths drilled (between 19.0 and 20.5 feet below existing grades). A loose section of silty sand was encountered between depths of about 7.5 to 14 feet in one boring. Cobbles and boulders were encountered within the granular soils. Groundwater was encountered at depths ranging from about 8 to 13 feet below existing grade. A generalized subsurface cross-section that includes the Woodlawn Bridge borings is provided in Figure 9-14. The approximate location of the cross-section is shown in Figure 9-13.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

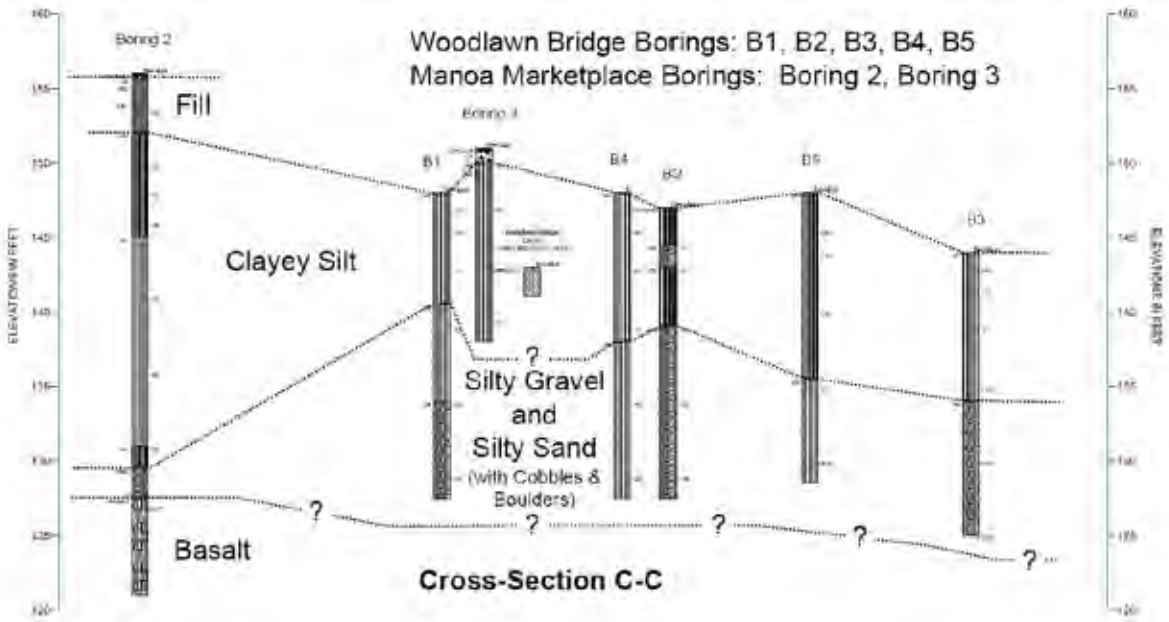

Figure 9-14: Cross-Section C-C Based on Woodlawn Bridge Borings

For the Manoa Marketplace borings (Boring and Test Pit-series in Figure 9-13), the borings disclosed generally similar conditions throughout the borings for that project. Approximately 3 to 8 feet of heterogeneous fill was encountered at the surface. The fill consisted of soft to stiff clayey silt to silty clay and loose to medium dense silty sands and gravel. The fill contained varying amounts of boulders, debris, and organic matter. The silts and clays varied from slightly to highly expansive. The fill was underlain by a clayey silt zone that was 5 to 20 feet thick. The silt was underlain by sand and gravel-sized cinder material and decomposed basalt and basalt boulders in a silt matrix. Groundwater was only encountered in one boring (Boring 2) at a depth of 19 feet (EL 136 feet MSL). The generalized subsurface cross-sections provided in the Foundation Investigation are included in Figure 9-15. The approximate location of these cross-sections is shown in Figure 9-13.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

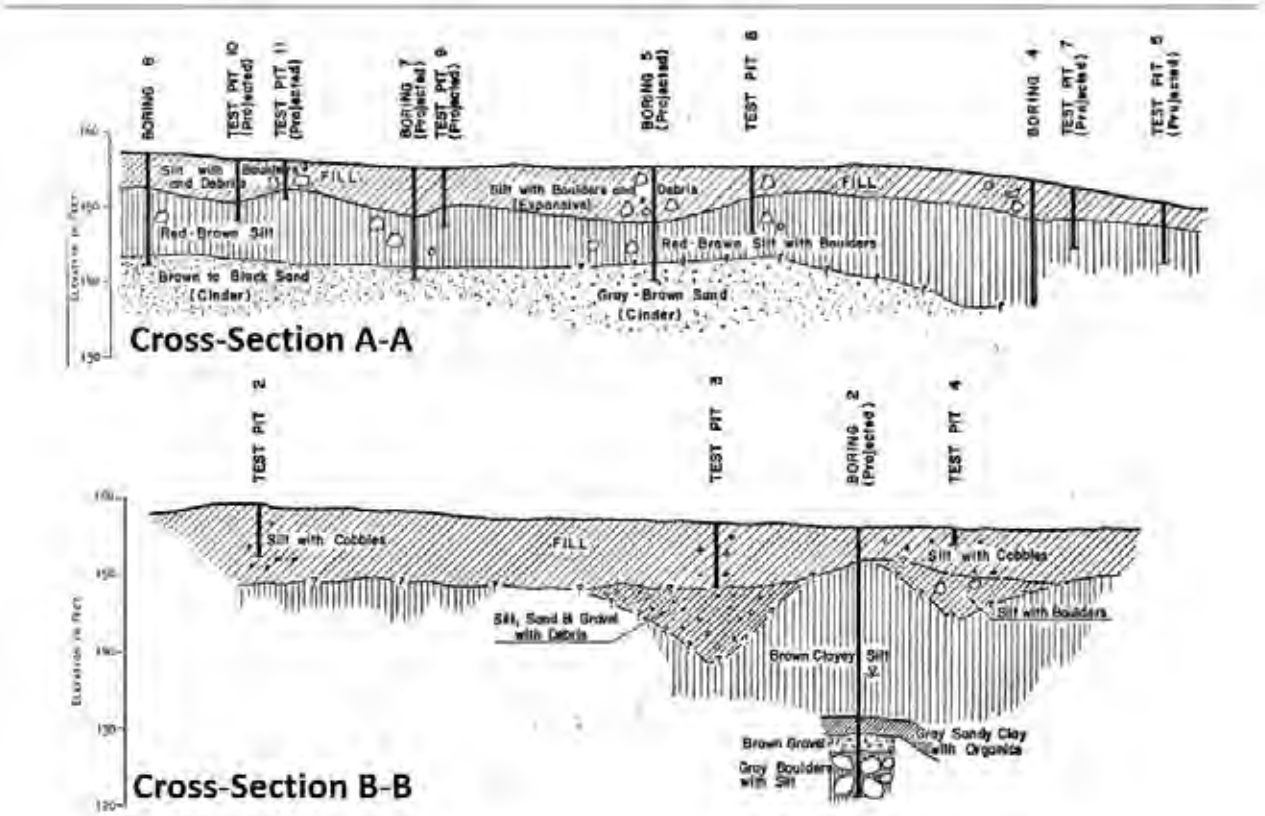

Figure 9-15: Cross-Sections from Manoa Marketplace Foundation Investigation

Lava flows from the Tantalus Peak and Sugar Loaf vents were mapped under approximately the eastern 410 feet of the proposed floodwall. The subsurface conditions in the area of this geologic formation generally were expected to be consistent with the subsurface conditions depicted in Cross-Section A-A of Figure 9-15. However, based on the conditions encountered in the available borings mapped within this formation and closest to Manoa Stream (e.g., Boring 2 and Boring 3 from the Manoa Marketplace borings and borings B1 and B4 of the Woodlawn Bridge borings), the subsurface conditions in the area of this mapped formation near the creek appeared to be more consistent with the areas mapped as lava flows associated with the Ko'olau Basalt (i.e., the subsurface conditions depicted in Cross-Section C-C included in Figure 9-14).

Based on the above paragraph, for planning and budgeting purposes, the conditions along this entire measure alignment were assumed similar to those depicted in Cross-Section C-C (Figure 9-14). As such, 25 feet of overburden soils comprised of clayey silt, silty sand, and silty gravel (i.e., soil) over 15 feet of basalt (rock) were assumed, with difficult drilling assumed below 11 feet.

Groundwater was assumed to be below expected mass excavation depths for the L-wall, although it may be encountered above the tip of the planned macropiles.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

9.4.4. Additional Comments

The wall must be designed to minimize lateral load transfer to the grout-filled riprapped streambanks. In general, the direction of loading is expected to be away from the riprap. In addition, macropiles are battered to help reduce lateral movement of the proposed wall.

9.5. Koali Road Floodwall

9.5.1. General Description

The Koali Road Floodwall tentatively will consist of a 6-foot-tall L-wall founded on macropiles. The western leg of this “L-shaped” floodwall is located along Manoa Stream, while the southern leg of floodwall is located along Palolo Stream. The Koali Road Floodwall is shown in Figure 9-16 and is located in a residential area with little to no real estate available to accommodate the wall construction, creating severe space limitations.

Figure 9-16: Koali Road Floodwall

Specifically, along the Manoa section, there was only 12 to 15 feet available between existing residential buildings and an existing CRM wall that extended to the base of the stream as shown in Figure 9-17. An access road occupied most, if not all, of the 12 to 15-foot distance. In addition, there was a waterline that traversed the eastern side of the access road. An overhead electric line restricting overhead space traversed the other side of the access road. Ideally, construction will not impact the CRM wall since it is relatively new construction (which would also help keep construction out of the stream channel). The streambed generally was on the order of about 10 feet below the roadway but was up to about 15 feet below the roadway in the southern portion of this section. Rock was exposed in the stream bottom in the southern portion of the section along Manoa. The section also included some waterfalls due to the aggressive drop in elevation at some locations. The section along Manoa dropped over 10 to 15 feet from

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

north to south. At the confluence of the Manoa and Palolo Streams, there was approximately 15 to 20 feet of difference between the road elevation and the stream elevation, and rock appeared to drop off quickly in that area.

Figure 9-17: Existing Walls at Manoa & Palolo Streams. Waterfall at Manoa.

The Palolo section of the planned L-wall was located in the backyards of houses along Kamakini Street where the distance between the existing canal wall and the residential structures generally was on the order of 20 to 25 feet but as close as 5 to 12 feet. The existing canal wall (Figure 9-17) included a concrete wall and concrete bottom and generally was on the order of 10 feet deep along most of the section but was as little as approximately 5 to 6 feet at the eastern end of the proposed floodwall (i.e., the section along Palolo generally drops 5 feet or less from east to west). No information was available on the design or construction of the existing concrete canal walls and bottom, which meant raising the wall without modification to the underlying structure was an extremely unlikely solution. Since disturbance to these walls was not desirable, current plans include the proposed wall being offset directly behind the existing walls. A sewer line traversed the backyards, which also limits the proposed wall location or requires relocation of the utility (relocation planned). There was an overhead electric line restricting overhead space for at least part of the proposed alignment along Palolo Stream.

9.5.2. Geology

According to the geologic map, the Koali Road Floodwall is underlain mostly by (Holocene) Alluvium as shown in Figure 9-18, except for the far eastern end of the section along Palolo Stream, which is underlain by Lava Flows. The mapped (Holocene) Alluvium is surrounded by various types of lava flows. Furthermore, basalt consistent with lava flows was exposed at the stream bottom for the southern portion along Manoa (except near the confluence of Manoa and Palolo Streams), as well as across (to the north of) Dole Street from Kanewai Community Park, which is located at the north end of the planned floodwall.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Figure 9-18: Koali Road Floodwall Geology

According to the geologic map, the Alluvium is comprised of unconsolidated deposits of silt, sand, and gravel along streams and in valley bottoms. In some areas, the Alluvium grades upslope to talus and colluvium. Where information is lacking, Alluvium may include deposits more appropriately assigned to older alluvium by virtue of greater consolidation or topographic settings not at grade with modern drainages.

The Lava Flow mapped at the eastern end of the Palolo section consists of columnar jointed massive lava and flows typically described as ‘a‘ā. ‘A‘ā are lava flows that have a rough rubbly surface composed of broken lava blocks called clinkers. The Lava Flow thickness reportedly generally varies from 15 to 30 meters (49 to 98 feet) where well exposed. Some flows (for example, Kalihi and Pali) contain lherzolite (ultramafic igneous rock) xenoliths (a piece of rock trapped in another type of rock)**.**

9.5.3. Assumed Subsurface Conditions

There were no borings along the proposed floodwall alignment; although, there was one set of borings from the Part A and Parts B & C Soils Investigations at Kanewai Park (Hirata & Associates, 2011a and 2011b, respectively) as shown in Figure 9-19. There was one water well nearby with subsurface information (1883 Waialae Road and Manoa), and two other nearby water wells that did not include subsurface information (1895 Kanewai Park and 1884 Booth Estate). The subsurface information from these nearby borings and one well, as well as site observations regarding rock outcrops, was used to inform the assumed subsurface conditions for the proposed floodwall.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

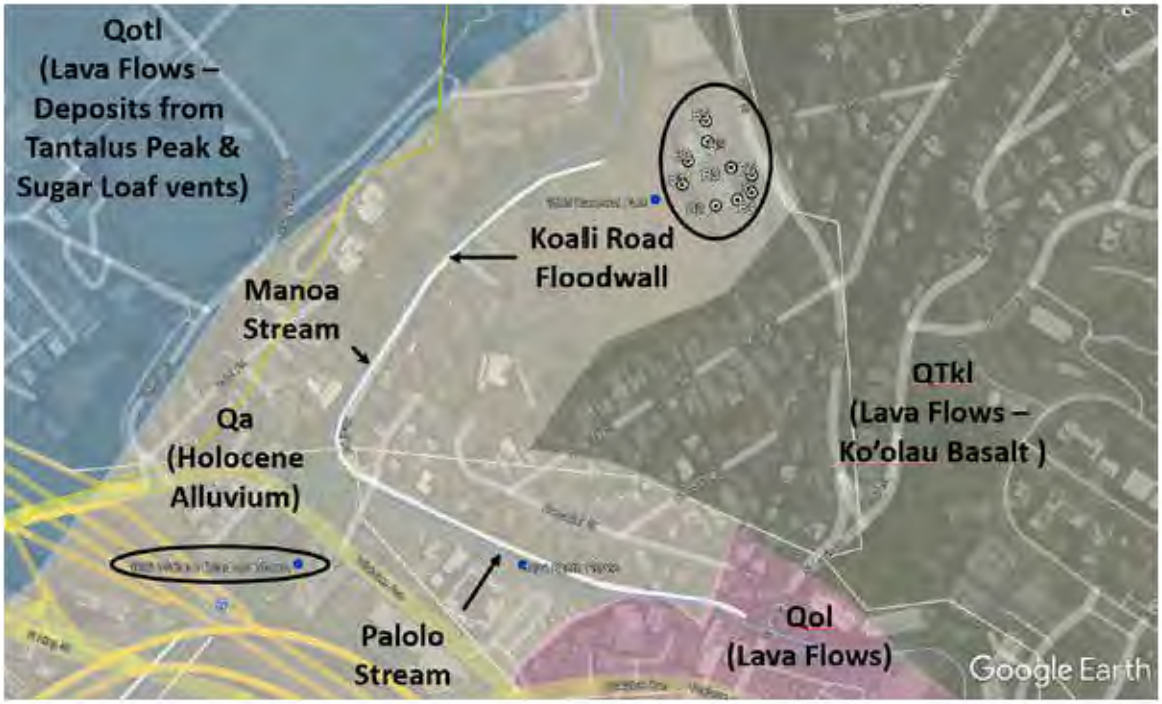

Figure 9-19: Koali Road Floodwall Nearby Borings & Wells

Approximately 5 to 7 feet of high plasticity, clayey (MH) silt fill was encountered at the surface of most of the Kanewai Park borings. The upper elevations of the site had clearly been filled to achieve current grades, as evidenced by a tall CRM wall. The fill was underlain by a thin layer (typically 5 feet or less) of naturally occurring high plasticity, medium stiff to stiff, clayey (MH) silt. The clayey silt transitioned into clay silt that included cobble and boulders. The cobbles and boulders required coring techniques to penetrate in some borings, while the layer could be penetrated with augers in other borings. The cobbly/bouldery soil generally extended to boring termination depths that varied from 14 to 29 feet. A photo of the base of an overexcavation into the cobbly/boulder soil that was included as part of a construction field report, dated September 19, 2013, attached to the Parts B & C Soils Investigations at Kanewai Park is included in Figure 9-20. Medium hard to hard, moderately fractured, moderately weathered basalt was encountered in one boring (boring B9). This boring was located near Dole Street, where a lava flow (basalt) rock outcrop was observed across the street from the park as shown in Figure 9-21.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Figure 9-20: Kanewai Park Excavation

Figure 9-21: Outcrop Across Dole Street from Kanewai Park

In the 1883 Waialae Road and Manoa water well, 30 feet of soil followed by 5 feet of “boulders” followed by 15 feet of clay followed by 18 feet of “boulders” followed by 38 feet of clay followed by 40 feet of coral was encountered. The soil deposits in the upper 30 feet were not characterized while the lower 40 feet (coral) was characterized as consolidated marine sediments laid down by several different stands of the sea. The remaining deposits were characterized as consolidated and partly consolidated older alluvium, ancient talus and landslide deposits, and marine sediments, except for the first 5 feet of boulders that also were classified as possible unconsolidated marine deposits.

Based on all the above information, for planning and budgeting purposes, the following subsurface conditions were assumed:

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

1. The subsurface conditions at the northern end of the section along the Manoa Stream to the northern termination of Koali Road (approximately 515 feet) were assumed to consist of 29 feet of cobbly/bouldery medium stiff to stiff clay deposits (soil with difficult drilling) over sound basalt (rock) transitioning to 10 to 15 feet of cobbly/bouldery medium stiff to stiff clay deposits (soil with difficult drilling) over sound basalt (rock) at the northern termination of Koali Road. For macropile budgeting purposes, 515 linear feet of cobbly/boulder (soil with difficult drilling) over 11 feet of basalt (rock) were assumed.
2. From the northern termination of Koali Road to the bend at Koali Road (approximately 555 feet), the subsurface conditions were assumed to consist of 10 to 15 feet of cobbly/bouldery medium stiff to stiff clay deposits (soil with difficult drilling) over sound basalt (rock). It is expected that the macropiles in this section likely be shorter than the assumed 40-foot length due to the solid rock observed at the stream bottom. However, for macropile budgeting purposes, 555 linear feet of 30 feet of cobbly/boulder deposits (soil with difficult drilling) and 10 feet of basalt (rock) were assumed.
3. From the bend at Koali Road to the eastern termination point at Palolo Stream (approximately 1,415 feet), the subsurface conditions were assumed to consist of 30 feet of soil (with difficult drilling) followed by 5 feet of “boulders” (drilled as rock/soil difficult drilling) followed by 15 feet of clay (with difficult drilling). For macropile budgeting purposes, 1,415 linear feet of 35 feet of cobbly/boulder deposits (soil with difficult drilling) and 5 feet of basalt (rock) were assumed.

9.5.4. Additional Comments

The floodwall was located in a residential area with extremely tight access considerations, as well as low overhead and underground utility considerations, including a water line along Manoa and a sewer along Palolo. The cost estimate and real estate considerations should reflect the relocation of these utilities. In addition, the cost estimate should account for the inefficiency created by the tight access considerations. For example, macropiles likely will have to be installed in batches, instead of all at one time, because once the macropiles are installed access to wall areas past the recently installed macropiles will be difficult (i.e., wall to occupy 12 feet of the 12 to 15-foot access path so it not possible to drive over area once macropiles are installed). In other words, the macropile contractor will do their work for a section followed by the concrete contractor, with this process repeating until the entire wall length is completed. This limitation will create higher costs, requiring multiple mobilizations and an extended construction schedule for the different construction crews (e.g., the macropile and concrete contractors). Alternatively, instead of staggering the construction schedule, consideration could be given to installing all the macropiles but temporarily backfilling around the macropiles to create an access road above them, with the temporary backfill re-excavated with the remaining wall construction. Furthermore, some staging in the adjacent canal during dry periods may be necessary. Due to the severe space restrictions, construction will be difficult, expensive, time-consuming, and likely require innovative solutions.

The wall must be designed to minimize lateral load transfer to the existing CRM and concrete walls. In general, the direction of loading was expected to be away from the existing features. In addition, macropiles were battered to help reduce lateral movement of the wall.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

One structure was identified within the footprint of this proposed floodwall. The impacted structure is shown in Figure 9-22 and was located between the pedestrian bridge at Kaluawaa Street and the termination of the floodwall at St. Louis Drive.

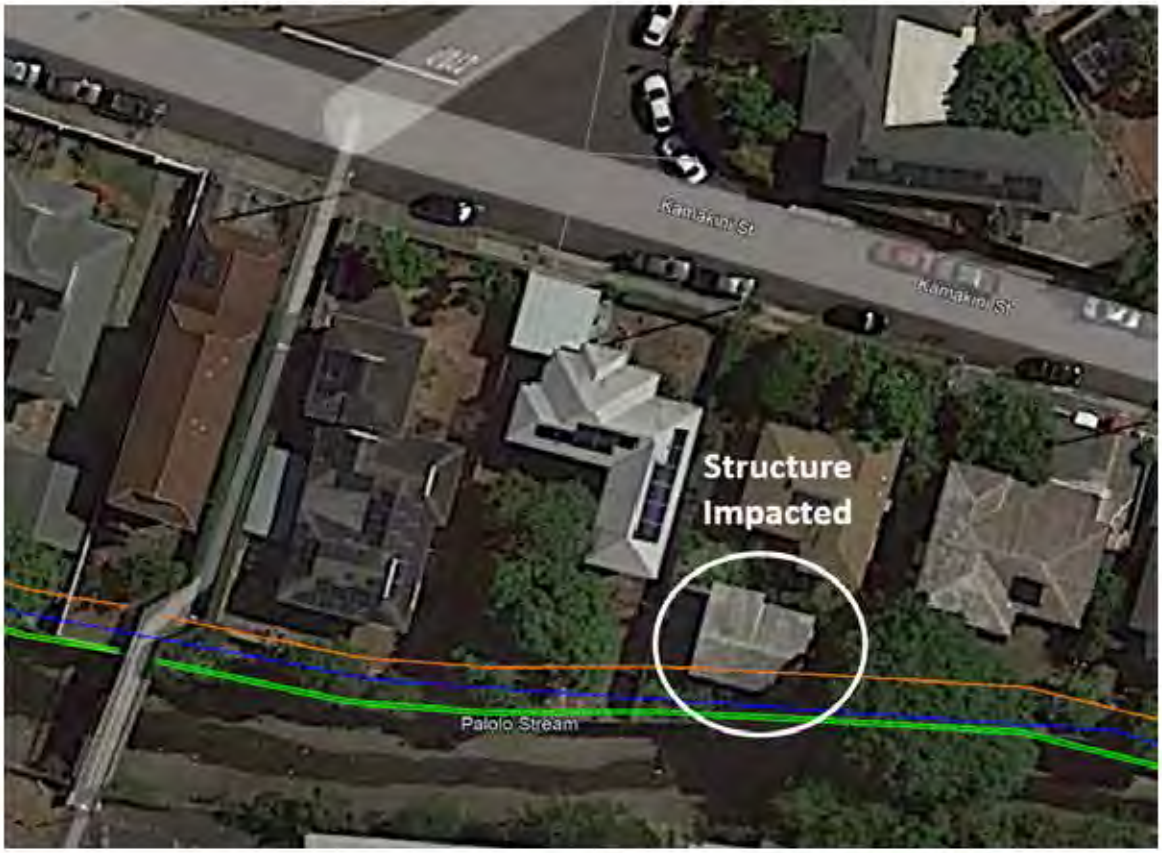

Figure 9-22: Impacted Structure on Kamakini Street on Koali Floodwall

It may be possible to avoid demolition of this structure during the design phase with a creative wall design in the local area; however, more evaluation and analysis than feasible during this phase of the project is required to evaluate the feasibility of this possibility. One possible solution would be to design the floodwall for this 30-foot distance to span where the structure is located and distribute the load to specially designed abutment structures on each side. Alternatively, a different wall configuration with a smaller footprint may be possible in the area, with some of the load distributed to specially designed abutment structures on each side. It is also possible that a smaller wall footprint may be possible in this area, because the required wall height may be less since it is near the termination of the wall. This area will need to be evaluated again once actual survey data is available so that the ground elevations and location structures are better understood.

No details on the existing Palolo canal wall design or construction were available at the time of this report. In addition, an accurate survey of existing features (e.g., building locations) and ground surface elevations was not available. As a result, there is a risk of complications during the design and construction phases if actual conditions vary from those assumed. These complications could increase costs or make the planned approach unviable, thereby requiring development of a new approach.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

9.6. Kaimuki High School Floodwall (and Extension)

9.6.1. Aerial photo showing the Makiki District Park Detention Basin (grass field).General Description

The Kaimuki High School Floodwall tentatively will consist of a combination of 6-foot-tall L-wall founded on macropiles along the stream and 6-foot tall I-wall away from stream flow (for the alternative array evaluation only – this I-wall section of wall was converted to an L-wall for the TSP). The floodwall will encompass the area of the track, a playing field, and an open grass field as shown in Figure 9-23. The area was relatively flat and generally sloped to the northeast.

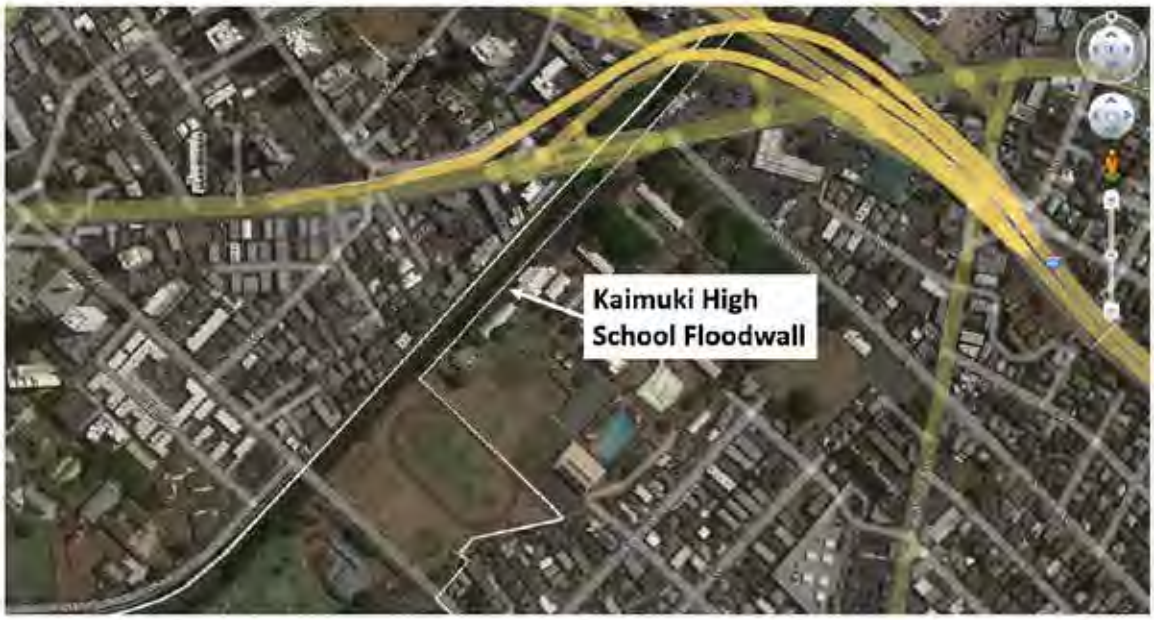

Figure 9-23: Kaimuki High School Floodwall (Alternate 5 Configuration Shown)

9.6.2. Geology

According to the geologic map, the Kaimuki High School Floodwall is underlain by (Holocene) Alluvium as shown in Figure 9-24.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Figure 9-24: Kaimuki High School Geology

According to the geologic map, the Alluvium is comprised of unconsolidated deposits of silt, sand, and gravel along streams and in valley bottoms. In some areas, the Alluvium grades upslope to talus and colluvium. Where information is lacking, Alluvium may include deposits more appropriately assigned to older alluvium by virtue of greater consolidation or topographic settings not at grade with modern drainages.

9.6.3. Assumed Subsurface Conditions

There were no borings along the proposed floodwall alignment; however, there were several soil test borings and water wells within approximately 350 to 500 feet of proposed alignment as shown in Figure 9-25. As a result, the subsurface information from these nearby borings and wells was used to inform the assumed subsurface conditions for the proposed floodwall.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

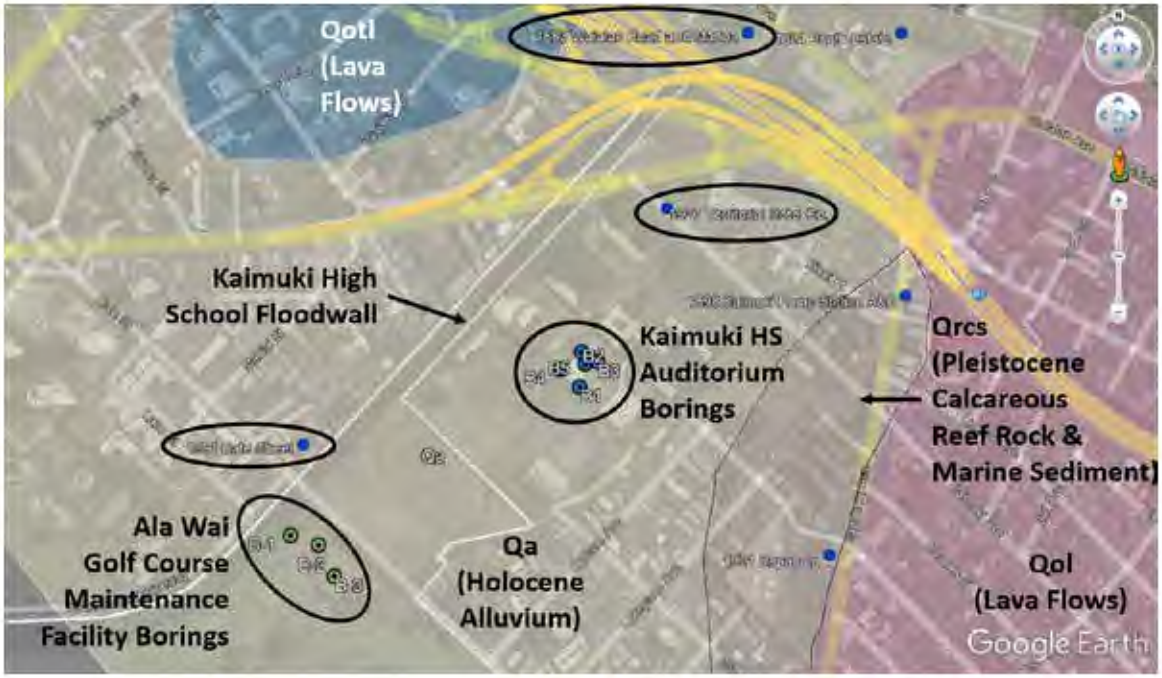

Figure 9-25: Kaimuki High School Nearby Borings & Wells

Approximately 3 to 6 feet of fill over approximately 80 feet of soft, compressible alluvial and estuary deposits were encountered in the borings advance for the Kaimuki High School Auditorium (Hardin-Lawson Associates, 1976). A hard coral ledge was encountered 45 feet below grade in the boring further from the proposed wall (boring B3) while basalt rock was encountered 78 to 87 feet below the ground surface in other borings. The old Manoa-Palolo Channel traversed the general area of the proposed floodwall as shown in Figure 9-29. The deeper borings may have been located in the old drainage channel. Eight (8) inches of settlement was predicted for 6 feet of new fill placement due to the soft soils at the Auditorium project. Octagonal, precast, prestressed concrete driven piles 16.5-inch in diameter and bearing in the coral ledge were recommended for heavier auditorium loads due to the soft soils and large anticipated settlements. These piles were estimated to be 110 feet long in the old drainage channel and 50 to 60 feet long where the rock ledge was shallower. Groundwater reportedly stabilized at EL 3 feet MSL.

The apparent coral ledge reported in the Auditorium borings also was visible during the site reconnaissance (March 2022) at the bottom of the southern/western portion of the Manoa-Palolo Stream along which part of the floodwall ran. These visual observations of rock at the stream bottom seemed to be confirmed by the subsurface conditions reported for the 1881 Date Street well where 19 feet of unconsolidated marine deposits and consolidated and partly consolidated older alluvium, ancient talus and landslide deposits, and marine sediments (11 feet of “soil”, 3 feet of “fine gravel”, and 5 feet of gravel) overlying 15 feet of coral deposits was reported.

The soil test borings for the Ala Wai Golf Course Maintenance Facility (Fewell Geotechnical Engineering, 1993) also encountered coral deposits, with 10 feet of coralline detritus reported in one boring 20 feet below grade. The soils over the coralline detritus reportedly were comprised of a thin layer of alluvial deposits underlain by lagoonal deposits. According to the Maintenance

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Facility geotechnical report, “the lagoon deposits and coral detritus consisted (of) loose to very loose silty sands and gravel. These soils possess low shear strengths and are highly compressible.” Groundwater was encountered at EL 0 to 1 feet MSL. The subsurface investigation report reported “the loose to very loose lagoon deposits and coral detritus are highly compressible and can result in large settlements under large areal loading or heavy, concentrated loads” and “estimated settlements of up to 3 inches would normally be anticipated under the planned 6-foot-thick areal fill.”

In the Territorial Hotel water well, located in the northern section of the proposed floodwall, 70 feet of clay, reported to be unconsolidated marine deposits or consolidated/unconsolidated older alluvium, ancient talus and landslide deposits, and marine sediments, was encountered.

In the 1883 Waialae Road and Manoa water well, 30 feet of soil followed by 5 feet of “boulders” followed by 15 feet of clay followed by 18 feet of “boulders” followed by 38 feet of clay followed by 40 feet of coral was encountered. The soil deposits in the upper 30 feet were not characterized while the lower 40 feet (coral) was characterized as consolidated marine sediments laid down by several different stand of the sea. The remaining deposits were characterized as consolidated and partly consolidated older alluvium, ancient talus and landslide deposits, and marine sediments, except for the first 5 feet of boulders that also were classified as possible unconsolidated marine deposits.

Groundwater was assumed to be consistent with the conditions encountered in the Kaimuki High School borings. Groundwater reportedly stabilized at EL 3 feet MSL in these borings, while ground surface elevations at the time of that report varied from EL 14.8 to 16.1 feet. Based on this information, groundwater is expected to be below typical excavation levels, but above the tip of macropiles.

Based on the available information, the Manoa-Palolo Stream used to be located further east of the current location and was slowly eroding in a westerly direction; and a coral ledge approximately 20 feet below existing grades appeared to be located along the existing Manoa-Palolo Stream channel. For planning and budgeting purposes, the following subsurface conditions were assumed:

1. The subsurface conditions in the immediate vicinity of the stream channel (i.e., for the L-walls with macropiles) were assumed to consist of 20 feet of soil and 20 feet of coral (rock/difficult drilling).
2. The subsurface conditions away from the stream channel (i.e., for the I-walls) were assumed to consist of 40 feet of soil, with the lower 20 feet consisting of difficult driving. The upper 20 feet was assumed to be comprised of generally soft to loose, compressible soil deposits that can be penetrated by the sheet pile provided the sheet pile tip is properly accessorized with a driving shoe to penetrate boulders or other obstructions.

9.6.4. Additional Comments

The depth to rock or a hard layer was assumed to be sufficient that the planned 18-foot of sheet pile embedment for the I-wall can be achieved. However, borings will be necessary to confirm this assumption. The L-wall with macropiles may have to be extended to areas where rock is too shallow to permit driving of the sheet piles.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

9.7. Ala Wai Golf Course Detention

9.7.1. General Description

The Ala Wai Golf Course Detention tentatively will consist of a 6- to 9-foot-tall levee (berm), with 9-foot L-walls along Ala Wai Canal. The levee will encompass the existing Ala Wai Golf Course, which primarily included open grass fields and isolated and dispersed wooded/overgrown areas associated with the golf course. The area was relatively flat and generally sloped to the south, toward the Ala Wai Canal. The existing conditions, along with the planned detention area, are shown in Figure 9-26. Please note the change in levee configuration and the addition of an L-wall section for the TSP as shown in Figure 4-2.

Figure 9-26: Ala Wai Golf Course Detention

9.7.2. Geology

According to the geologic map, the northern portion of the Ala Wai Golf Course Detention is underlain by (Holocene) Alluvium while the southern portion is underlain by (Holocene) Fill, and the eastern edge is underlain by Calcareous Reef Rock and Marine Sediment (Pleistocene) as shown in Figure 9-27.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Figure 9-27: Ala Wai Golf Course Detention Geology

According to the geologic map, the Alluvium is comprised of unconsolidated deposits of silt, sand, and gravel along streams and in valley bottoms. In some areas, the Alluvium grades upslope to talus and colluvium. Where information is lacking, Alluvium may include deposits more appropriately assigned to older alluvium by virtue of greater consolidation or topographic settings not at grade with modern drainages.

The (Holocene) Fill is comprised of man-made fill forming piers and harbor breakwaters along the coastline.

The (Pleistocene) Calcareous Reef Rock and Marine Sediment is comprised chiefly of emerged coral reefs but includes finely laminated lagoonal limestone. The reefs consist of coral heads and coralline algae cemented by a lime matrix.

9.7.3. Assumed Subsurface Conditions

There were numerous borings located at the golf course as summarized in the following reports: Subsurface Investigation Report: Ala Wai Maintenance Facility (Fewell Geotechnical Engineering, 1993); Geotechnical Engineering Report, Proposed Clubhouse (C.W. Associates, 1987a); Geotechnical Engineering Report, New Floodlights (C.W. Associates, 1987b); Geotechnical Engineering Exploration, Net Poles (C.W. Associates, 1990); and Foundation Investigation, Irrigation Pump House (Hirata & Associates, 2002). However, the borings were concentrated in two areas: the northern corner and the eastern portion of the site, both areas where there were existing structures. Refer to Figure 9-28 for the location of borings at this measure site. Large portions of the golf course have no boring coverage as shown in Figure 9-28.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Figure 9-28: Ala Wai Golf Course Detention Nearby Borings & Wells

This particular site had a very complex set of geologic conditions due to the proximity to the ocean, which resulted in multiple coral ledges, and old channels from all the streams on the island that discharged to the ocean. The old stream channels eroded the other geologic formations and deposited alluvial soils in the eroded channels. The approximate location of some of these old, eroded channel features and coral ledges are depicted in Figure 9-29. Because of the complex geologic history of this measure site and the limited available borings, only broad subsurface assumptions at this measure site were made, with the recognition that the conditions in other locations may vary significant from those assumed.

Figure 9-29: Old Channels, Coral Ledges & Coral Depths

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

It was assumed that coral deposits generally were present between approximately 5 and 30 feet below existing grades, except where the old drainage channels were located. The coral deposits were assumed to be overlain by very soft, very loose, highly compressible soils. In the historical eroded channels, these highly compressible deposits may easily extend 50 feet or more below existing grades. The levee construction will be most impacted by the near surface soil deposits. Depending on how soft the existing surface soils are, some subgrade stabilization (e.g., lime or cement stabilization) may be required to construct the levee.

Groundwater was assumed to be at EL 0 to 1 foot MSL, which was approximately 2 to 3 feet below existing grades along the Ala Wai Canal transitioning to approximately 10 feet below existing grades at the higher elevations of the site furthest away from the Ala Wai Canal.

9.7.4. Additional Comments

The eastern end of this measure site was underlain by the calcareous reef rock that is believed to be the source of the Mo'ili'ili Karst, which has been known to impact deep foundation installations and cause surface subsidence to a lesser degree. There are no known issues with this particular formation in the area, even though it is at shallow depth. The formation is shallower in this area as compared to the established area of known Mo'ili'ili Karst. In addition, stable groundwater is very shallow due to its proximity to the ocean. The major factor that triggers karst development is the high rates of downward water movement and the dissolution associated with the heavy rainfall. The shallow groundwater limits the depth path of this infiltrating rainwater. Regardless, this concern should not be eliminated from consideration until additional site reconnaissance and data gathering are conducted and borings are advanced during the design phase.

9.8. Ala Wai Canal Floodwall

9.8.1. General Description

The Ala Wai Canal Floodwall tentatively consisted of a combination 6-foot-tall L-wall founded on macropiles (along the stream) and 6-foot tall I-wall (away from stream flow) for the alternative array. For the TSP, a J-wall along the Ala Wai Canal and a tieback I-wall along the Manoa-Palolo Stream between Date Street and Kapiolani Boulevard are planned.

This measure will encompass both sides of the Ala Wai Canal, the Ala Wai Golf Course, some of the Kaimuki High School playing fields, and the Manoa-Palolo Stream from the Ala Wai Canal to Highway 1 as shown in Figure 9-30. The Ala Wai Canal Floodwall also requires implementation of the Kaimuki High School Floodwall and Ala Wai Golf Course Detention. Refer to Section 9.6 and Section 9.7, respectively, for additional information regarding the subsurface information in these areas. The discussion in this section is limited to the Ala Wai Floodwall exclusive of the Kaimuki High School Floodwall and the Ala Wai Golf Course Detention conditions, except where additional comments due to changes in the approach are applicable (e.g., I-wall originally planned for this measure during the alternative array analysis but converted to levee for the TSP at the Ala Wai Golf Course).

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Figure 9-30: Ala Wai Canal Floodwall

9.8.2. Geology

According to the geologic map, the Ala Wai Canal Floodwall is underlain by (Holocene) Fill or (Holocene) Alluvium, except at the far eastern end of the Ala Wai Golf Course, which is underlain by Calcareous Reef Rock and Marine Sediment (Pleistocene) as shown in Figure 9-31.

Figure 9-31: Ala Wai Canal Floodwall Geology

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

According to the geologic map, the Alluvium is comprised of unconsolidated deposits of silt, sand, and gravel along streams and in valley bottoms. In some areas, the Alluvium grades upslope to talus and colluvium. Where information is lacking, Alluvium may include deposits more appropriately assigned to older alluvium by virtue of greater consolidation or topographic settings not at grade with modern drainages.

The (Holocene) Fill is comprised of man-made fill forming piers and harbor breakwaters along coastline. Based on the subsurface conditions encountered in the borings in the area, it appears the fill is underlain by compressible lagoonal or alluvial deposits.

The Calcareous Reef Rock and Marine Sediment (Pleistocene) is comprised chiefly of emerged coral reefs but includes finely laminated lagoonal limestone. The reefs consist of coral heads and coralline algae cemented by a lime matrix.

9.8.3. Assumed Subsurface Conditions

In addition to the borings associated with Ala Wai Golf Course described in Section 9.7.3, borings from the following reports also were located along the proposed Ala Wai Canal Floodwall alignment: Soils Investigation, New Playcourts, Ala Wai Neighborhood Park (Hirata & Associates, Inc., 2004); Ala Wai Canal Wall Repairs (Geolabs, 2017 and 2018); Updated Interim Geotechnical Memorandum Foundation Recommendations, Ala Wai Pedestrian Bridge (YKE, 2020); Foundation Investigation: Proposed Waikiki Banyan Square Project Kuhio Avenue at Kanekapolei Street (Dames & Moore, 1981); Subsurface Geology of Waikiki, Moiliili, and Kakaako with Engineering Application, Master Thesis (Ferrall, 1976); Foundation Investigation, Proposed Flood Light Poles, Ala Wai Park (Dames & Moore, 1974); and Project Completion Report for Subsurface Geology and Hydrogeology of Downtown Honolulu: Engineering and Environmental Implications, Phases I and II (Finstick, 1998). Refer to Figure 9-32 for the location of borings at the site. Large portions of the alignment have no boring coverage as shown in Figure 9-32.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Figure 9-32: Ala Wai Canal Floodwall Nearby Borings & Wells

This particular site has a very complex set of geologic conditions due to the proximity to the ocean, which resulted in multiple coral ledges, and old channels from all the streams on the island that discharged to the ocean that eroded other geologic formations and deposited alluvial soils in the eroded channels. Some of these known features are depicted in Figure 9-33. Because of complex geologic history of the site and the limited available borings, only broad subsurface assumptions at this measure site were made.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Figure 9-33: Old Channels, Coral Ledges & Coral Depths

The conditions in the nearby borings and wells varied, but it generally appeared that compressible deposits overlying a coral ledge were encountered, with the coral ledge generally encountered 20 to 30 feet below existing grades, consistent with the coral ledge reported in the Master Thesis entitled “Subsurface Geology of Waikiki” (Ferrall, 1976). The coral ledge appeared to be missing where old drainage channels were located.

Based on this information, for planning and budgeting purposes, 30 feet of soil drilling and 10 feet of rock (coral) drilling were assumed for the macropiles. Discussion of the I-walls associated with this measure are discussed further in Section 9.8.4. These I-walls likely will be converted to levee. Refer to Section 9.7.3 for appropriate subsurface assumptions regarding the levee at the Ala Wai Golf Course.

Groundwater was assumed to be at EL 0 to 1 foot MSL, which was approximately 2 to 3 feet below existing grades along the Ala Wai Canal and deeper as existing grades increased heading north away from the ocean.

9.8.4. Additional Comments

For the alternative array evaluation, I-wall was assumed along the eastern and northern perimeter of the Ala Wai Golf Course Detention. However, due to the shallow rock in this area, the I-wall was converted to levee for the TSP. If real estate considerations become problematic during the design phase, then the levee in those areas will be converted to L-wall with macropiles.

There were no details on the existing canal wall design or construction available at the time of this report. As a result, there is a risk of complications during the design and construction phases if actual conditions vary from those assumed. These complications could increase costs or make the planned approach unviable, thereby requiring development of a new approach.

The depth to rock along the Manoa-Palolo in the vicinity of the Kaimuki High School will impact the design of the tieback I-wall. Borings will be required in this area to better understanding the depth to rock along this section and the potential implications on the tieback I-wall design. In addition, construction of the tieback I-wall is expected to be expensive and difficult given the tight space restrictions and limited working areas. Flexible and innovative solutions may be required to successfully implement construction.

Shallow rock will be a factor for the J-walls and L-walls planned at the east end of the Ala Wai Canal. Rock is exposed along both the north and south canal faces. Shallow rock could impact the easternmost 1,000 to 1,500 feet of the walls in this area. Additional borings are necessary to better understand the potential impact and extents of the shallow rock.

The eastern end of this measure site was underlain by the calcareous reef rock that is believed to be the source of the Mo’ili’ili Karst, which has been known to impact deep foundation installations and cause surface subsidence to a lesser degree. There are no known issues with this particular formation in the area, even though it is at shallow depth. The formation is shallower in this area as compared to the established area of known Mo’ili’ili Karst. In addition, stable groundwater is very shallow due to its proximity to the ocean. The major factor that triggers karst development is the high rates of downward water movement and the dissolution

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

associated with the heavy rainfall. The shallow groundwater limits the depth path of this infiltrating rainwater. Regardless, this concern should not be eliminated from consideration until additional site reconnaissance and data gathering are conducted and borings are advanced during the design phase.

9.9. Ala Wai Canal Floodwall (with Kaimuki Extension)

This measure is a combination of the Ala Wai Canal Floodwall and the Kaimuki High school floodwall. As a result, refer to Section 9.8 for information on the Ala Wai Canal Floodwall and Section 9.6 for information on the Kaimuki High School Floodwall.

9.10. Makiki Floodwall

9.10.1. General Description

The Makiki Floodwall tentatively will consist of a U-wall founded on macropiles. The floodwall will be located on both sides and the bottom of the existing Makiki Stream, starting at the termination of the culvert under Fern Street heading toward the Ala Wai Canal.

The floodwall is located in a heavily populated area. Existing development, including single-family homes, multi-family homes, high-rise buildings, and commercial development, is located immediately adjacent to either side of the stream. The existing conditions, along with the planned floodwall location, are shown in Figure 9-34.

Figure 9-34: Makiki Floodwall

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

The current stream bottom is a mix of concrete and unimproved ("natural") conditions based on on-site observations and cross-sections provided of an upstream area. Unfortunately, no cross-sections are available for the proposed floodwall area. In the proposed floodwall area, the stream bottom is obscured by the backwater from the Ala Wai Canal, making direct observation impossible. The existing walls along the stream seem to match the depicted cross-section and generally are comprised of mortared lava rock/concrete rubble masonry (CRM) walls.

9.10.2. Geology

According to the geologic map, the Makiki Floodwall is underlain by (Holocene) Fill as shown in Figure 9-35.

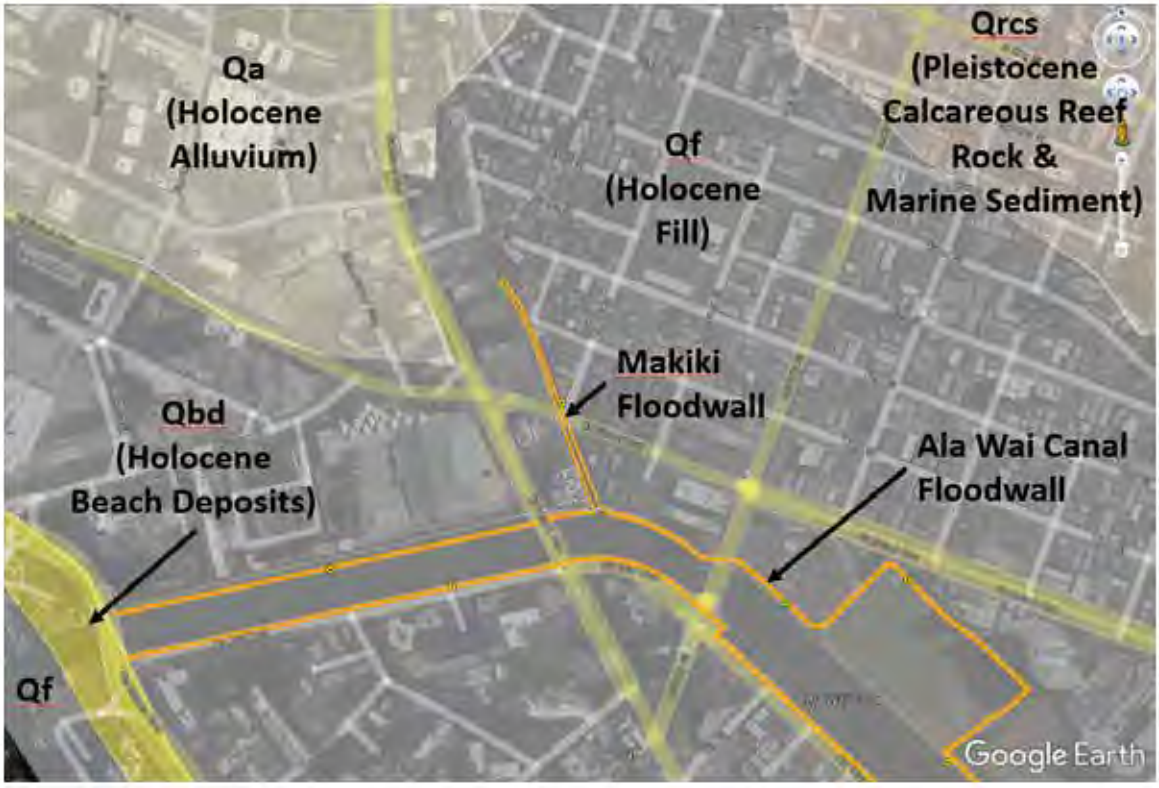

Figure 9-35: Makiki Floodwall Mapped Geology

According to the geologic map, the (Holocene) Fill is comprised of man-made fill forming piers and harbor breakwaters along coastline. Based on the subsurface conditions encountered along the Ala Wai Canal, it appears the fill, if encountered, probably is underlain by compressible lagoonal or alluvial deposits. The lagoonal and alluvial deposits generally are expected to be comprised of unconsolidated deposits of silt, sand, and gravel.

9.10.3. Assumed Subsurface Conditions

There was no soil boring or well information in the immediate vicinity of the Makiki Floodwall. However, there was on one boring (B-201) located approximately 300 feet southeast (upstream) of the confluence of Makiki Stream and the Ala Wai Canal. In addition, there was a water well (referred to as 1883 King Street and Kalakaua Avenue) located approximately 0.4 mile upstream (north) of the proposed floodwall alignment. Refer to Figure 9-36 for the location of

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

this boring and well in relation to the proposed floodwall alignment. No subsurface information regarding the well located approximately 0.4 mile east of the proposed floodwall (referred to as 1967 Kewalo Basin) was located.

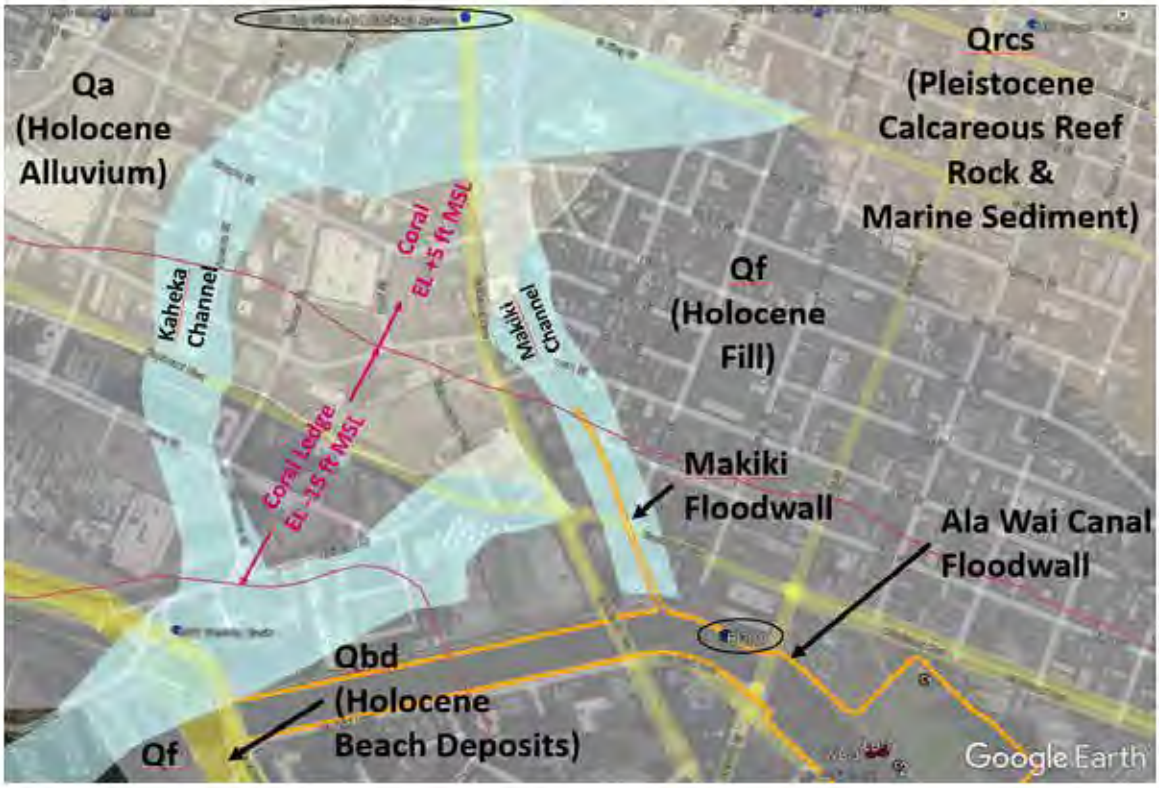

Figure 9-36: Makiki Floodwall Old Channels/Nearby Borings & Wells

Unconsolidated marine deposits were encountered in the upper 60 feet of the nearby water well to the north. The unconsolidated marine deposits were underlain by 30 feet of coral deposits. The nearest boring (boring B-201) extended to a depth of 52.5 feet (Ala Wai Canal Wall Repairs, Geolabs, 2018). The upper 6 feet of deposits were comprised of fill. The fill generally was underlain by coralline deposits intermixed and interlayered with lagoonal and alluvial deposits of various consistencies (e.g., soft to stiff, very loose to dense). A coralline layer overlying a coral layer was encountered from approximately 24 to 32 feet below grade, and a limestone layer was encountered from approximately 39 to 42 feet below grade.

The soil conditions at this proposed floodwall likely are controlled by the erosional and depositional nature of the Makiki Stream but also may be complicated by the proximity to the ocean where multiple coral ledges and old channels from all the streams on the island that discharged to the ocean may exist. Some of these coral ledges and old channels are depicted in Figure 9-36.

Because of complex geologic history of the site and the limited available borings, only broad subsurface assumptions at this measure site were made. For planning and budgeting purposes, unconsolidated marine deposits were assumed to be present to depth of at least 60 feet. It is assumed that the coral ledge in the area of the stream has been eroded away.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Groundwater was assumed to be at the ground surface since the proposed alignment is located in the backwater area of the Ala Wai Canal, where the ground surface is covered by at least several feet of creek water most of the time.

9.10.4. Additional Comments

To facilitate construction of the planned wall, significant ground improvement may be required in areas where the bottom of the stream is not comprised of concrete due to the likely soft, saturated nature of the creek bottom deposits. A concrete bottom is expected to be located in isolated areas since concrete appeared to have placed only at erosional areas of concern. It is anticipated that ground improvement would consist of the placement of a layer of granular material to bridge the soft soils. Depending on the quality of the soils at the creek bottom, some removal may be required to achieve adequate stabilization. However, removal near the existing walls should be limited due to concerns regarding destabilizing existing wall foundations or their bearing soils.

Due to the close proximity of structures to the existing canal walls, destabilization of the existing wall foundations is a significant concern and limitation during construction, because the structures behind the wall could be damaged if the existing canal wall loses its support system. As a result, the proposed wall will have to be constructed in short sections. For example, excavation for the new wall foundation (the top of which would correspond to the existing creek bottom) would be constructed in sections not more than 10 feet long at one time to maintain stability of existing canal walls, with no more than one 10-foot section excavated in a 50-foot section. Foundation slabs would then be constructed in a “leapfrog” fashion until a continuous new bottom is constructed.

There were no details on the existing wall design or construction available at the time of this report. In addition, an accurate survey of existing feature (e.g., building locations) and ground surface elevations was not available. As a result, there is a risk of complications during the design and construction phases if actual conditions vary from those assumed. These complications could increase costs or make the planned approach unviable, thereby requiring development of a new approach.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

10. Other Considerations

10.1.1. Load Testing

Loading testing of piles and anchors typically is separated into two categories: verification testing, which is testing generally conducted prior to full-scale production to confirm that design assumptions are appropriate, and proof testing, which is testing conducted to confirm that the production process remains consistent. Verification testing typically is conducted to higher loads than proof testing (e.g., 2 to 2.5 times the design load versus 1.25 to 1.5 times the design load).

Load testing of both macropiles and tieback anchors will be required. The frequency of load testing is dependent on many factors including, but not limited to, the type of project, the complexity of subsurface conditions, the likelihood of unknown/anomalous conditions, availability of previous pile test data, and level of experience with the pile type in similar subsurface conditions. The frequency of testing should be established during the design phase, but the following was recommended for budgeting purposes in the feasibility phase:

- Verification testing of 0.5% of the total macropiles.
- Proof testing of 2 percent of the total macropiles – On large projects, verification testing typically is recommended for at least 1 percent of the production piles. For projects where a single pile failure could be detrimental to the overlying structure (such as a bridge where redundant pier supports are not included in the design), verification testing is recommended for at least 5 percent of production piles. A testing frequency reduced from 5 percent was deemed reasonable, since the piles are part of a continuous wall where a single pile is unlikely to adversely affect the overall performance of the structure. However, a testing frequency higher than the 1 percent assumed for a typical project was deemed appropriate for this stage of planning, since both vertical and lateral load testing may be required (but this will not be known until the design phase).
- Verification testing on the first 2 to 3 tieback anchors and 4 percent of the remaining anchors – The testing frequency for a typical project is 2 percent of the remaining anchors. The increase in testing frequency recommended is because it is assumed that the subsurface conditions will not be well-defined due to limited boring accessibility.
- Proof testing of every tieback – Tiebacks are one of the few structural systems where every member typically is tested before placing them into service.

10.1.2. Pre-Condition Surveys

This project is located in a highly developed area where construction will occur very close to existing structures. Pre-condition surveys should be expected since existing structures likely will be in or near the influence zone of the construction, especially at the tieback I-wall. Recommendations regarding where and when to conduct pre-condition surveys should be developed during the design phase once the final design details are known.

10.1.3. Monitoring Surveys

For reasons similar to those provided for the pre-condition surveys, monitoring of vibrations and noise should be expected, especially at the tieback I-wall. Recommendations regarding where and when to install monitoring equipment and what type should be developed during the design phase once the final design details are known.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

11. Future Exploration

There is insufficient boring coverage for design purposes at the proposed measure locations. There is considerable risk that the subsurface conditions will vary from those assumed for the purposes of this report due to this lack of information. There is the potential for there to be significant changes in the design features (e.g., to the size and length of foundation system to even the type of foundation system) once the actual subsurface conditions are determined.

Borings and laboratory testing to investigate the actual soil and rock conditions at each specific feature location are required to confirm the design assumptions for this report and to further refine designs for design purposes. It will be important that the borings identify the characteristics (strength, cementation, continuity, etc.) of any rock-like deposits encountered (e.g., coral, lava, tuff, etc.) due to the irregular nature of these deposits, especially if macropiles are end-bearing on these rock-like deposits. Borings should be regularly and closely spaced due to the natural variation in the soil and rock deposits in the project area.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

12. Risks

Among the numerous risks involved in this sizable project, the following major geotechnical considerations were identified:

1. The lack of subsurface information (borings) at planned feature locations – The type, size, and other important design features of foundation elements (e.g., pile spacing, pile reinforcing, or pile length) are based on assumed subsurface conditions. If those conditions vary from those assumed, significant changes to the foundation types and overall design may result, up to including requiring a change in planned foundation approach, especially if conditions are worse than assumed or if rock is shallower than expected. These changes could have significant cost impacts.

2. The severe space (both lateral and overhead) limitations – Several features have severe space limitations due to existing structures being in very close proximity to the planned features (e.g., Koali Road, Makiki, and Manoa-Palolo from Date Street to Kapiolani Floodwalls). These limitations restrict the available footprint for foundations, which impacted foundation approaches, but are more likely to severely limit the feasible approaches to construction. Creative approaches to some aspects of construction will be required to address these limitations, such as using small cranes for the work or working from the adjacent canals. These severe space limitations are expected to increase construction costs significantly, while also requiring extended construction schedules.

3. The lack of design and construction information on structures nearby or immediately adjacent to planned features (e.g., Ala Wai Canal walls, Makiki Stream walls, Palolo canal walls, structures along the Koali Floodwall, structures at the tieback I-wall, etc.) – No details on the existing canal walls design or construction were available at the time of this report. In addition, an accurate survey of existing features (e.g., building locations) and ground surface elevations was not available. As a result, there is a risk of complications during the design and construction phases if actual conditions vary from those assumed as the details regarding these existing features may impact the proposed structures. These complications could increase costs or make the planned approach unviable, thereby requiring development of a new approach.

4. Existing utilities – The project site is located in a heavily developed areas with extensive utilities that will impact design and construction. Increased costs are associated with existing utilities due to both accommodating them during design and working around them during construction. As a result, identifying the location, type, depth, and size of these utilities is critical for the design phase so their full impact is better understood. Despite best efforts, identification of all utilities that will impact the design and construction of a project of this size and complexity during the feasibility (and even the design) phase is nearly impossible. Utilities likely will be identified during future work that will impact either design or construction.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

This document contains CONTROLLED UNCLASSIFED INFORMATION (CUI). It contains information that may be exempt from public release under the Freedom of Information Act (5 USC 552). It is to be controlled, stored, handled, transmitted, distributed, and disposed of in accordance with USACE policy relating to CUI information and it is not to be released to the public or other personnel who do not have a valid “need to know” without prior written approval of an authorized USACE official.

Report Status: Draft, November 2023

Executive Summary

The study is the General Reevaluation Report with Integrated Supplemental Environmental Impact Statement for the Ala Wai Canal. The Ala Wai Watershed has previously overtopped the Canal and flooded downtown Waikiki multiple times since 1965. Waikiki is the most important economic driver for the state, accounting for approximately 7% of the gross state product and 7% of all civilian jobs in the state. The flood characterization in the basin can be divided into three distinct areas: Mānoa, Pālolo and Makīkī valleys with fast moving water (velocities capable of moving vehicles and large debris) and localized overland flooding. Using these three distinct areas the technical team came up with measures and alternatives to present to the vertical team. After 6-8 months of screening measures that were purposed internally and ideas from the local people of Oahu, the technical team narrowed down the measures and alternatives from upwards to 150 measures to four alternatives utilizing 8 measures. There where number factors that went into screening a measure, from practicality, the projected cost of a measure, and any large-scale utility relocation. The Civil project delivery team (PDT) members main roles and responsibilities for this project were identifying existing utilities, constructability of a measure, preliminary grading, and calculating quantities.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

1.0 Introduction

1.1. General Description

The Ala Wai Watershed is located on the island of O'ahu, which has undergone major land-use changes in the past 100 years. Since 1950 the resident population of the island has more than doubled. Honolulu, the capital city located on the island of O'ahu, is now considered the most densely population city in the Nation. Urbanization on O'ahu has been accompanied by substantial alterations to stream systems, including changes in water quality, instream habitat, riparian habitat, and the introduction of nonnative species. An extensive study conducted in the 1970s, showed that 57 percent of the streams on the island of O'ahu had been channelized, 58 percent had water exported from them, and all had roads crossing over them. Modifications of the stream ecosystems have been most severe at the lower elevations where urban growth is greatest. Artificially straightened reaches with concrete-lined flat-bottomed channels and revetted reinforced banks are common in the urban areas of the study. Such modifications are commonly accompanied by removal of riparian vegetative cover, and a reduction in substrate complexity.

The Honolulu/Waikiki Beach area has experienced repeated damage from flooding of the Manoa, Palolo, and Makiki streams, all of which drain to the Ala Wai Canal, which then outlets directly to Mamala Bay and to the Pacific Ocean. The Ala Wai Canal is a 2-mile-long waterway constructed in 1928 to drain extensive coastal wetlands, thus allowing development of the Waikiki District.

The watershed encompasses 19 square miles (12,064 acres) and extends from the ridge of the Ko'olau Mountains to the nearshore waters of Mamala Bay see figure 1. The Palolo stream includes the Pukele and Waiomao tributary streams; and the Makiki stream includes the Kanaha tributary stream. The headwaters for all these streams are in steep mountainous terrain where intense rainfall occurs. The streams also collect surface water from the extensive urban development concentrated in the main valleys and the lower elevations of the watershed.

The two main problems identified for this project were the economic damages and elevated life risk resulting from riverine flooding along the Makiki, Manoa, and Palolo streams and the interplay between riverine and storm surge flooding along the Ala Wai Canal. The Technical team narrowed down over 150 measures to combat the flood problem and selected 4 design alternatives with one as the tentatively selected plan (TSP). Please see table 1 below. The purpose of this appendix is to evaluate the civil and site design considerations, quantities development and related construction considerations for each proposed flood risk measure.

1.2. Survey

Available survey data was provided by contract W9128A-15-D-0006 awarded to Sam O. Hirota Inc. Deliverables included CAD files and DTM surfaces that included 1 ft contours, utilities and property lines. Horizontal datum is based on Hawaii State Plane Coordinate System (U.S. Survey Feet), Zone 3, NAD 83 (PA11), Epoch 2010. Vertical Datum is based on Mean Sea Level (MSL), Local Tidal Datum (U.S. Survey Feet). This survey only covered the Ala Wai Golf Course Detention and portions of Ala Wai Canal Floodwall. Other survey information was provided by Honolulu GIS and Openroads Designer aerial imagery.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

2.0 Non-TSP Measures

2.1. Makiki District Park Detention

2.1.1. General Description

The Makiki District Park detention basin tentatively will consist of 6- to 10-foot-deep detention basin with 3H:1V side slopes and 1,200 feet of 6-foot tall I-wall around the basin perimeter. The detention basin will have an approximate 1 percent slope in an open grass field of Makiki District Park. The Makiki park will still be able to be used as an open field after construction. The proposed layout of the planned detention basin, inlet, and outlet are shown in figure 2 below. The proposed Inlet culvert has been modeled as a 20 ft by 4 ft reinforced concrete box (RCB) culvert. The proposed outlet pipe has been modeled as a 5 ft diameter culvert that drains into the Makiki stream after daylighting downstream of the H1 freeway. The total estimated disturbed area is roughly 3.39 acres.

Figure 2 - Makiki District Park Detention

2.1.2. Utilities

According to data publicly available on city and county Honolulu gis application, there are two sanitary sewer lines that are in the proposed project area shown in figure 3. The project area, also referred to as the project footprint, in other parts of this report is the area that would be impacted by construction to implement a project measure or project feature. Both are at a depth well below our proposed excavation of 50 ft above sea level. The diameter of sewer line A is 24

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

inches with inverts at 42.08 to 41.3. The diameter of sewer line B is 60 inches with inverts at 9.73 to 8.81. The inlet culvert coming from the Kanaha stream will have to cross over water, gas lines, and a sanitary sewer line. The water and gas line will have to be field verified for their inverts. The Sanitary sewer line that the inlet culvert will cross is 42.79. the proposed culvert will be well above the sanitary sewer line. The proposed outlet culvert leaving the makiki district detention basin will be crossing over water, gas lines, sanitary sewer, and Lunalilo Fwy (H1) line. The water and gas lines will have to be field verified for their inverts to ensure there this no need for relocation.

2.1.3. Staging Area

The staging area for this project can be in the area C shown in figure 3.

2.1.4. Quantities

According to power inroads cut: 21,768.88 cu yd, fill: 1,088.71 cu yd, net: 20,680.17 cu yd (cut). The Makiki district park disposal material could be utilized to construct the proposed Ala wai levee. Material is not suitable for being used as fill, the preconstruction and engineering design (PED) project delivery team (PDT) should work with the city and county to locate a state approved disposal area. One possible location would be the PVT land company that is northwest of the island. Measure will include approximately 2,200 LF of 20 ft x 4 ft reinforce concrete box culvert.

Figure 3 – Makiki District Park

2.2. Manoa Valley District Park Detention

2.2.1. General Description

The Manoa Valley District Park detention basin tentatively will consist of detention basin that will include 6- to 8-foot-deep cuts at the high (north) end of the site and 1,580 feet of 6-foot I-walls at

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

the low (south) end of the site. The detention basin will be in 4 playing fields that gently slope to the south approximately 15 feet of fall over 850 feet at Manoa Valley District Park. The existing conditions, along with the planned detention area are shown in Figure 4. The proposed Inlet culvert has been modeled as a 15 ft by 4.5 ft concrete box culvert. The proposed outlet pipe has been modeled as a 2-ft diameter culvert that drains into the downstream of the Manoa. The total estimated disturbed area is roughly 12.39 acres.

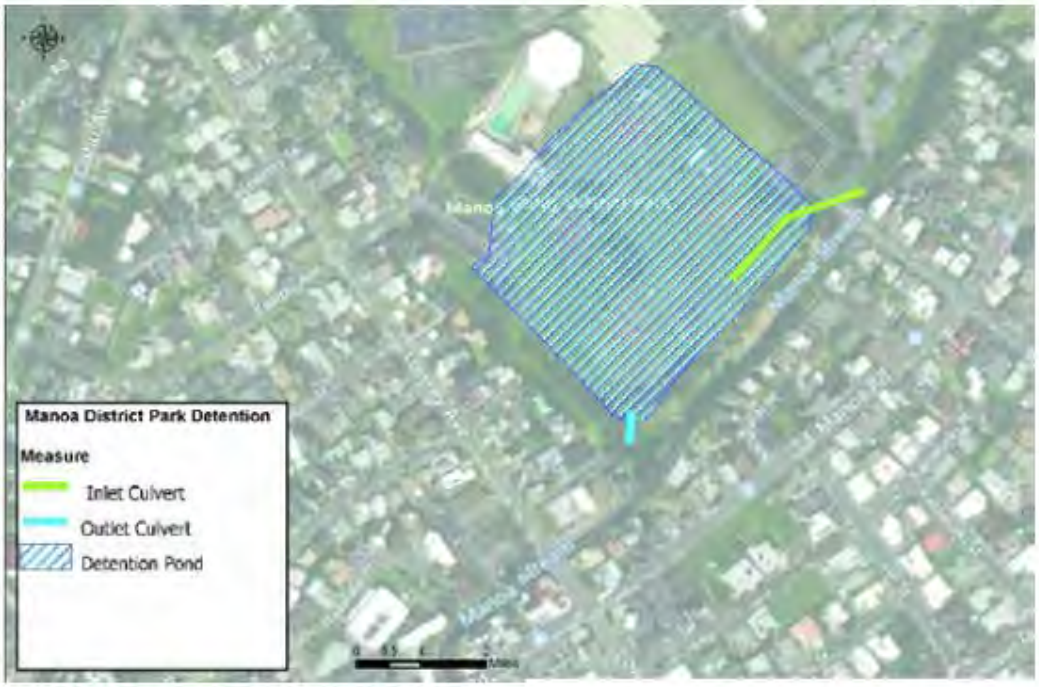

Figure 4 - Manoa District Park Detention

2.2.2. Utilities

According to data publicly available on city and county Honolulu GIS application, there is sanitary sewer main (A) that is running parallel with the proposed project area shown in figure 5. There is also a waterline (B) on the project area, this line would have to be verified by survey to confirm if the waterline would have to be relocated. The proposed inlet and outlet will be above the existing sanitary sewer lines.

2.2.3. Laydown Area

The Laydown area for this project can be in the area C shown in figure 5 below.

2.2.4. Quantities

According to MicroStation power inroads the proposed earthwork site cut: 97,654.73 cu yd, fill: 391.72 cu yd, net: 97,263.02 cu yd (cut). The Manoa district park disposal material could be utilized to construct the proposed Ala wai levee. For some reason the material is not suitable for being used as fill, the preconstruction and engineering design (PED) project delivery team (PDT) should work with the city and county to locate a state approved disposal area. One possible location would be the PVT land company that is northwest of the island.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Figure 5 - Manoa District Park Detention

2.3. Kanaha Floodwall

2.3.1. General Description

The Kanaha Floodwall tentatively will consist of a 2,200 long, 6-foot-tall L-wall founded on micropiles. The floodwall will be located on the south side of the existing Kanaha Stream. The floodwall is in a heavily populated area. Existing development, including single-family homes, multi-family homes, and high-rise buildings, is located immediately on either side of the stream. The existing ditch walls and bottom are lined, typically with concrete or mortared lava rock/concrete rubble masonry (also referred to as CRM).

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Figure 6 - Kanaha Floodwall

2.3.2. Utilities

According to data publicly available on the city and county GIS database, there are no underground utilities that would affect the Kanaha floodwall.

2.3.3. Laydown Area

The Laydown area for this project will be the same as the Makiki Detention project area C shown in figure 3.

3.0 TSP MEASURES

3.1. Ala Wai Golf Course Detention Basin

3.1.1. Measure Description

The Ala Wai Golf Course Detention Basin will consist of approximately 8,315 linear feet of earthen filled embankment, 240 linear feet of 6-ft L-wall on micro piles (see figure 8), and 1,620 linear feet of 9-ft L-wall on micro piles (see figure 9).

The earthen filled embankment will run along the Manoa-palolo left bank from Date Street to the Ala Wai Canal and then on the right bank of the Ala Wai Canal from Manoa-palolo to the Ala Wai golf course club house. The embankment will also run along the east and north sides of the golf course along Kapahulu Avenue and Date Street. The embankment was aligned to ensure the toe of slope is approximately 15 feet from the stream and canal and crosses known utilities perpendicular to the alignment. The embankment will range from 0 – 9 feet in height with a top of embankment elevation of 12 mean sea level (MSL) and will have 3H:1V side slopes. The

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

riverine side of the embankment will be armored with articulated concrete block (ACB) along the Manoa-palolo. An ACB armored spillway approximately 100 feet in length will be located along the Manoa-palolo. The embankment will have a 6 ft deep by 8 ft wide inspection trench. Soil condition of the golf course will require a 2H:1V side slopes of the inspection trench. Aggregate base course access roads are proposed at the top and toes of the embankment. The embankment will be hydroseeded to extend up to 15 feet past each toe. Please see geotechnical appendix for proposed soil condition of the embankment.

The 9-ft high L-wall will run along the Ala Wai canal right bank from the Ala Wai golf course club house to Kapahulu Avenue. The flood wall will be embedded into the embankments at the start and end of the alignment. The top of wall elevation will be set to 12 MSL and will have a maximum height of 9 ft. Please see figure 9 below. One road closure structure will be required at the entrance of the golf course. To maintain storage capacity within the detention basin (2) 12’ X 6’ reinforced concrete boxes (RCB’s) will be extended to the L-wall alignment and will back fill the outlet canal. See structural appendix for detailed cross sections of the wall.

The 6-ft L-wall will start at the end of the Ala Wai Canal Floodwall Measure located at the southeast end of the canal and will run northeast until it intersects with the 12-ft L-wall. See figure 8 below. See structural appendix for detailed cross sections of the wall.

A portion of the existing drainage ditch that runs along the north side of the golf course (parallel to Date Street) would be used as an inlet location to overflow into the Ala Wai Golf Course Detention Basin. A small inlet channel would be excavated and lined with ACB to improve the flow onto the golf course.

Figure 7 - Ala Wai Golf Course Detention

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

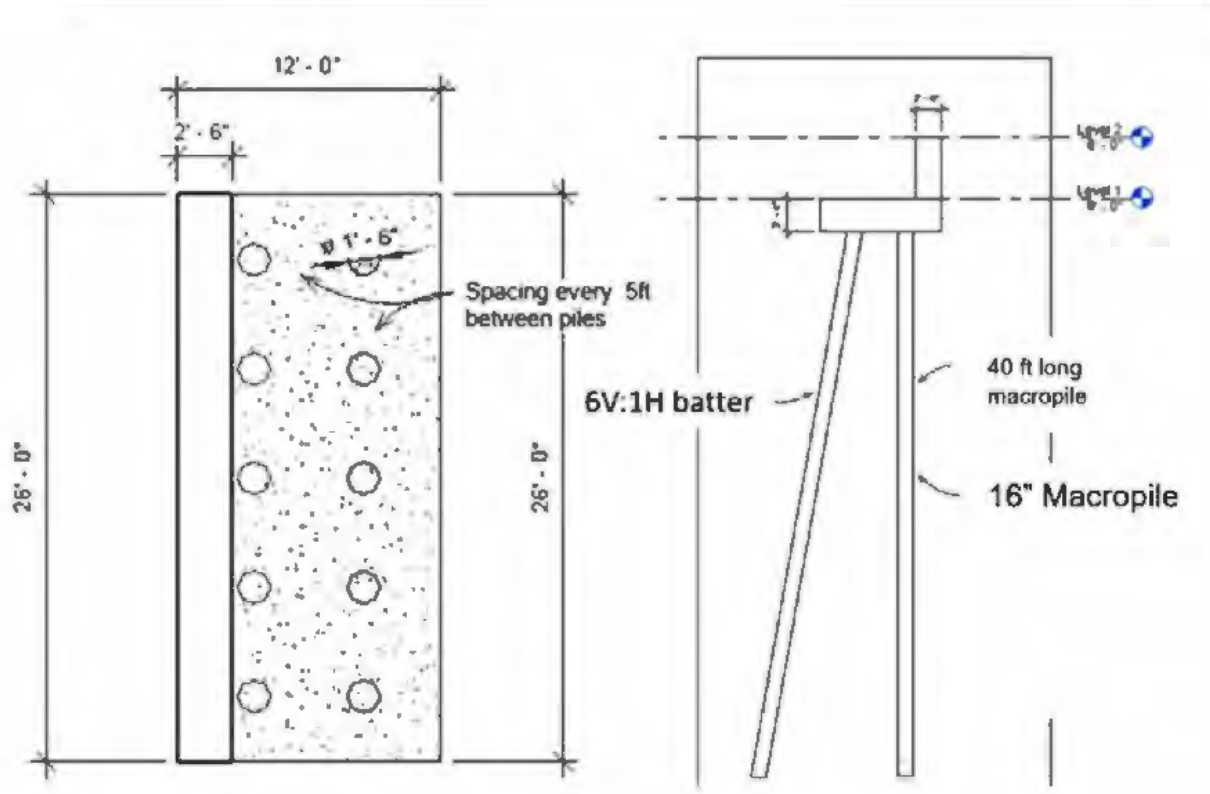

Figure 8 - 6-ft L-wall

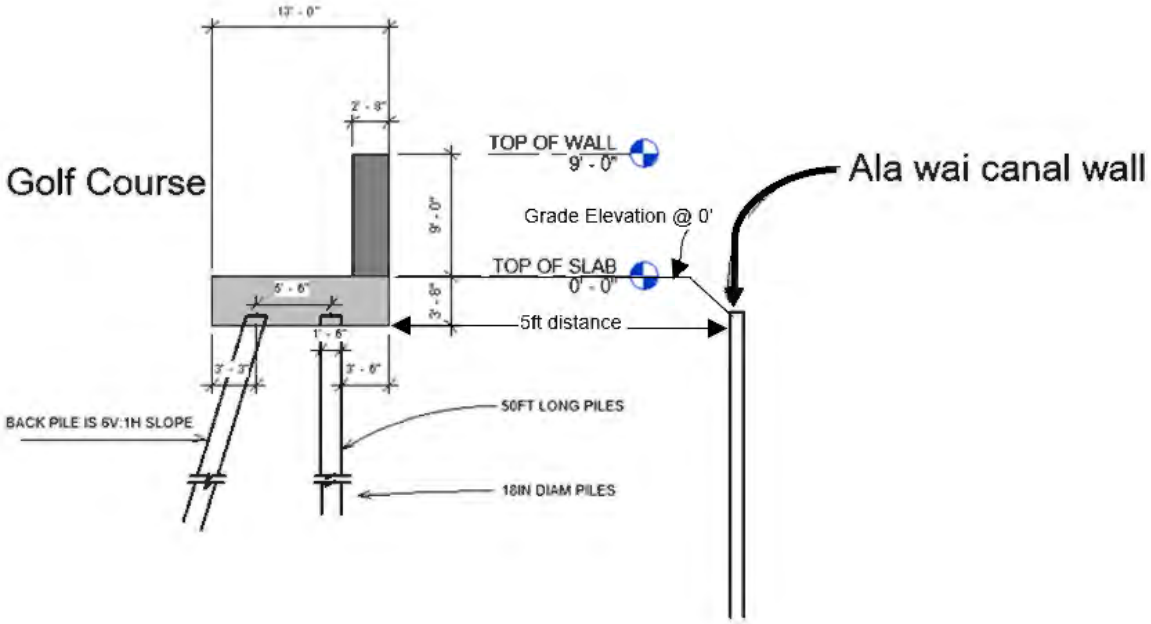

Figure 9 - 9-ft L-wall

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

3.1.2. Utilities

Several utilities are conflicting with the proposed project. The project delivery team (PDT) only identified known sewer, water, gas, storm, and power lines within the project area. Utilities within this area were identified based on the Hirtoa survey. Irrigation and communication lines were not identified in the scope of this project. Utilities conflicts were identified when crossing the proposed improvements and assumed 100 LF relocation when crossing the embankment and 60 LF relocation when crossing the flood wall. Storm drains greater than 36 inches were considered to have a drainage structure. Storm drains less than 36 inches were considered to have a flap gate. Table 2 below identifies the number of utility conflicts to be relocated or improved.

Table 3 - Ala Wai Golf Course Detention Basin Quantities

3.1.5. Constraints and Preconstruction Engineering Design Considerations

The preconstruction and engineering design (PED) project delivery team (PDT) must work with the local sponsor to establish a borrow site within the island. Due to limited real estate if no borrow site is established it may need to be imported via maritime traffic. Due to hydraulic modeling time constraints the feasibility team did not investigate the 9-ft L-wall being constructed around the (2) 12’ x 6’ RCB outlet canal. A flood wall around the outlet canal would eliminate the need for bridge reconstruction and extending the (2) 12’ x 6’ RCBs. Recommend exploring that option for cost savings.

3.2. Ala Wai Canal Flood Wall

3.2.1. Measure Description

The Ala Wai Canal Flood wall consist of approximately 22,850 linear feet of three wall types, L-wall, J-wall and I-Wall. Civil broke the measure into four sections to manage the size and quantities of the measure. The four sections will be Ala Wai Canal Right Bank, Ala Wai Canal Left Bank, Manoa-Palolo Right Bank, and Kaimuki High School Floodwall. See figure 10 below.

Ala Wai Canal Right Bank consist of approximately 7,400 linear feet of J-wall along the right bank of the Ala Wai Canal from Ala Moana Blvd. to the Manoa-Palolo confluence and along the right bank of Manoa-Palolo from the confluence to Date Street. The J-wall is a 6-ft tall wall with a 3-ft elevated walking path to allow pedestrians to see the canal and stream. The J-wall foundation will be 12-ft wide which rest on top of 40-ft deep mircopiles. The J-wall is aligned to be approximately 5-ft from the existing canal wall. See figure 11 below. See structural and geotechnical appendices for detailed information on the J-wall. There will be three road closure structures at Kalakaua Avenue, McCully Street, and Date Street. There will be three canoe closure structures along this alignment, two at Ala Wai Community Park and one off of Hihiwai Street.

Ala Wai Canal Left Bank consist of approximately 9,730 linear feet of J-wall along the left bank of the Ala Wai Canal from Ala Moana Blvd. to the end of the canal (approximately Ainakea

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Way). There will be two road closure structures at Kalakaua Avenue and McCully Street. The J-wall was aligned to be approximately 5-ft from the existing canal wall.

Manoa-Palolo Right Bank consist of approximately 1,650 linear feet of I-wall along the right bank from Date Street to Kapiolani Blvd. and approximately 670 linear feet of L-wall from Kapionlani Blvd. to Lunalilo Freeway (H1). The I-wall will be a 6-ft tall sheet pile wall encased in concrete at the wall steam and sheet piling driven approximately 30-ft below grade. Sheet piles will have tie backs at 50-ft on center. Due to the proximity to the existing buildings the PDT recommends use a Giken machine to drive the sheet piles. A temporary 15-ft wide bench will be constructed within the stream to allow room for equipment to drive in the tiebacks. The L-wall will be 6-ft in height with a 12-ft wide foundation that rest on top of 40 ft deep micropiles. See figures 8 and 12. See structural and geotechnical appendices for detailed information on the I-wall and L-wall.

Kaimuki High School Floodwall consist of approximately 3,400 linear feet of L-wall starting at the end of the north embankment of the Ala Wai Golf Course Detention Basin and runs northeast through Kiamuki High School and along the left bank of the Manoa-Palolo until it terminates at Lunalilo Freeway (H1) abutment. The measure will have two road closure structures Date Street and Kapionlani Blvd. Alignment was routed to maximum the use of the Kaimuki High School fields and minimize any potential takings if possible.

Figure 10 - Ala Wai Canal Flood Wall

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

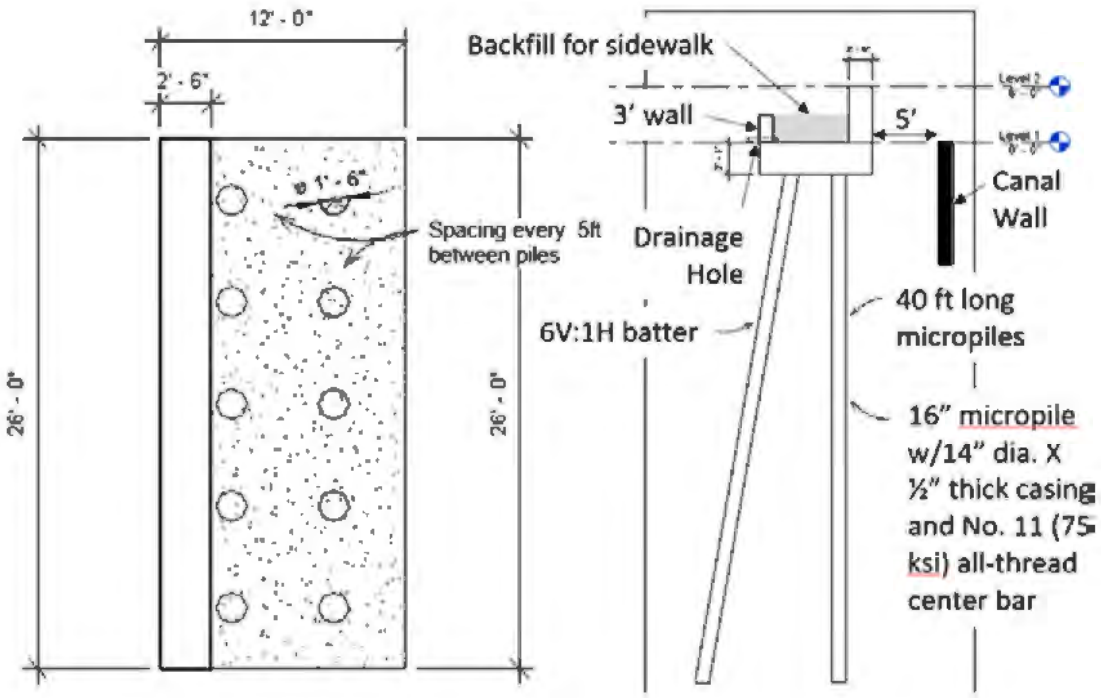

Figure 11 - J-wall

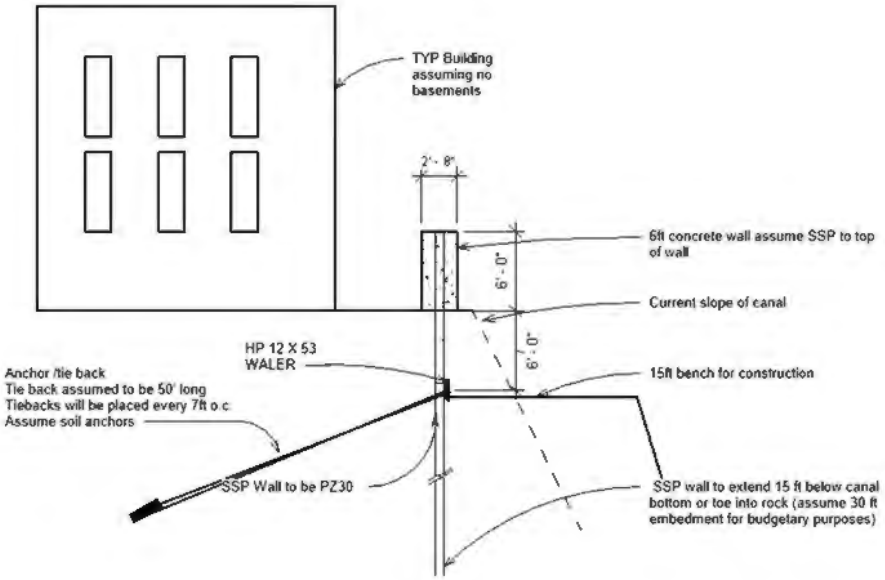

Figure 12 - I-wall

3.2.2. Utilities

Several utilities are conflicting with the proposed measure. The PDT only identified known sewer, water, gas, storm, and power lines within the project area. Utilities within this area were identified based on the Hirtoa survey and GIS information provided by the City of Honolulu. Irrigation and communication lines were not identified in the scope of this project. Utilities

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

conflicts were identified when crossing the proposed improvements and assumed 60 LF relocation when crossing the flood wall. There were several underground electrical conduits identified to run directly under and parallel to the proposed structures. The length of conflicting conduits to be relocated is reflected in the quantities. The Storm drains greater than 36 inches were considered to have a drainage structure. Storm drains less than 36 inches were considered to have a flap gate. Table 4 below identifies the number of utility conflicts to be relocated or improved.

3.2.3. Staging Area

Staging area for Ala Wai Canal Right Bank is proposed to be at Ala Wai Community Park. The Staging area for Ala Wai Left Bank is proposed to be at Ala Wai Golf Course or Ala Wai Community Park. Staging area for Manoa-Palolo Right Bank and the Kaimuki High School Floodwall is proposed to be at Kaimuki High School.

3.2.4. Quantities

Quantities are based on Openroads Designer commands such as linear measure, area measure, and end area method. Quantities were provided to assist with the cost estimate. Please see cost appendix for detailed cost analysis. Please see calculated quantities for the measure below.

Table 5 - Ala Wai Canal Flood Wall Quantities

3.2.5. Constraints and Preconstruction Engineering Design Considerations

Ala Wai Canal Left Bank and Right Bank were aligned to have a 5-ft offset from the existing canal wall per structures and geotechnical recommendations. The City of Honolulu intends to redesign and modify Ala Wai Blvd. The PDT did not have access to the new design therefore it was not accounted for during the study. The PED PDT must coordinate with the City of Honolulu to incorporate the new road design.

Accurate survey data was not made available for Manoa-Palolo Right Bank and Kaimuki High School Floodwall therefore the site alignment is based on aerial imagery provided by Bentley software Openroads Designer. Alignments may vary once accurate topographic surveys are conducted during PED. Utilities for these measures are based on Honolulu GIS information

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

therefore locations of the utilities are not to design accuracy which may or may not create more utility conflicts during PED.

Site design of the road closure structures for all measures were not accounted for due to the level of design effort required for this study. The PDT determined that the design of road closure structures would be determined and designed during PED. See the structural appendix for more information on suggested road closure structures.

3.3. Kaoli Road Floodwall

3.3.1. Measure Description

The Kaoli Road Floodwall consists of a 2,510-ft long, 6-foot-tall L-wall founded on micropiles. The western leg of the floodwall is located along the left bank of Manoa Stream, while the southern leg of the floodwall is located along the right bank of Palolo Stream. The Kaoli Road Floodwall is shown in Figure 13 and is in a residential area with little to no real estate available to accommodate the wall construction, creating severe space limitations. Kaoli road will have two road closure structure with one at Kaoli Road and the other at a pedestrian brigde located near Kaluawaa Street.

Figure 13 - Koali Road Floodwall

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

3.3.2. Utilities

Several utilities are conflicting with the proposed project. The PDT only identified known sewer, water, gas, storm, and power lines within the project area. Utilities within this area were identified based on GIS information provided by the City of Honolulu. Irrigation and communication lines were not identified in the scope of this project. Utilities conflicts were identified when crossing the proposed improvements and assumed 60 LF relocation when crossing the flood wall. There was a waterline and sewer line identified to run directly under and parallel to the proposed structures. There were also overhead power lines that run parallel to the proposed structure. The length of conflicting infrastructure to be relocated is reflected in the quantities. The Storm drains greater than 36 inches were considered to have a drainage structure. Storm drains less than 36 inches were considered to have a flap gate. Table 6 below identifies the number of utility conflicts to be relocated or improved.

FLAP GATE	2	EA
DRAINAGE STRUCTURE	2	EA
ROAD CLOSURE STRUCTURE	2	EA

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Table 7 - Koali Road Floodwall Quantities

3.3.5. Constraints and Preconstruction Engineering Design Considerations

Accurate survey data was not made available for this measure therefore the site alignment is based on aerial imagery provided by Bentley software Openroads Designer. Alignments may vary once accurate topographic surveys are conducted during PED. Utilities for these measures are based on Honolulu GIS information therefore locations of the utilities are not to design accuracy which may or may not create more utility conflicts during PED.

Alignment along the Palolo stream is constrained by the close vicinity of the residential structures. Based on aerial imagery used the PDT believes there is enough room to construct the wall however a detailed accurate land survey is critical for the construction of this measure.

3.4. Woodlawn Drive Floodwall

3.4.1. Measure Description

The Woodlawn Drive Floodwall consists of a 1,270-ft long, 6-foot-tall L-wall founded on micropiles. See figure 14. The floodwall will be located on the west side of Manoa Stream. The floodwall to the north of Woodlawn Bridge is in a grass area adjacent to a shopping center parking lot. The floodwall to the south of Woodlawn Bridge is located on University of Hawaii property for greenhouses and other agricultural activities. The measure will have one road closure structure at Woodlawn Drive.

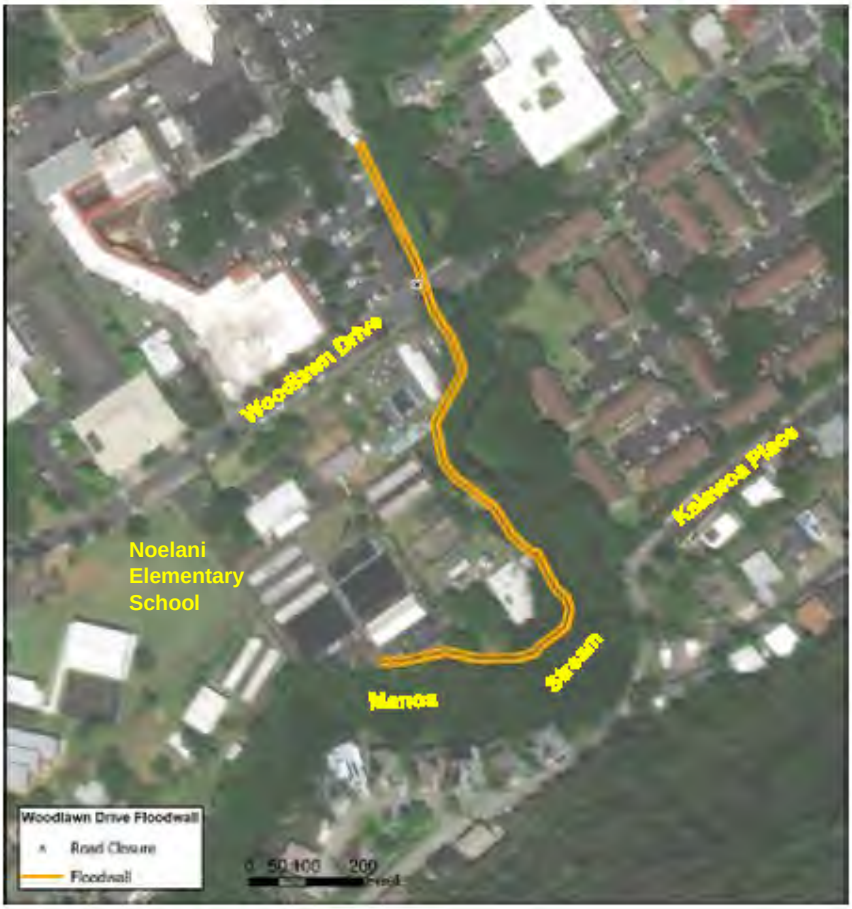

Figure 14 - Woodlawn Drive Floodwall

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

3.4.2. Utilities

Several utilities are conflicting with the proposed project. The PDT only identified known sewer, water, gas, storm, and power lines within the project area. Utilities within this area were identified based on GIS information provided by the City of Honolulu. Irrigation and communication lines were not identified in the scope of this project. Utilities conflicts were identified when crossing the proposed improvements and assumed 60 LF relocation when crossing the flood wall. Please see table 8 below for a list of utility conflicts.

Appendix F — Structural Engineering

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

This document contains CONTROLLED UNCLASSIFED INFORMATION (CUI). It contains information that may be exempt from public release under the Freedom of Information Act (5 USC 552). It is to be controlled, stored, handled, transmitted, distributed, and disposed of in accordance with USACE policy relating to CUI information and it is not to be released to the public or other personnel who do not have a valid “need to know” without prior written approval of an authorized USACE official.

Report Status: Draft, November 2023

Executive Summary

During the feasibility stage the PDT looked at variations of a dozen alternatives. Once selecting an Alternative (5) the PDT further investigated and selected Alternative 5.3 as the Tentatively Selected Plan

The Structural Designs were selected based on standard practice and Engineering Manuals. The restrictions of not having complete boring information, survey, and cross sections were some of the challenged placed on the structural design and engineering judgement played a role on determining what type of wall would be assumed to be adequate for the location it was chosen for.

I-walls were selected in areas where there would be no erosion or slopes near the wall type itself. Selected I-walls are 6 feet tall with sheet pile (PZ22) embedment depths of 18 feet below grade where the surrounding grades are relatively flat; or 24 feet below grade where the ground surface in front of the wall slopes down at 3H:1V.

Along stream channels, macropile-supported L-walls are planned. The L-walls will be 6 to 9 feet tall (6 feet in most locations / 9 feet at Ala Golf Course near the canal) with a 12- to 13-foot-wide base supported on cased macropiles. The macropiles are assumed to be 40 ft for the 6ft tall walls and 50 feet long for the 9ft tall walls. The piles will be 16 to 18 inches in diameter with a 14-to 16-inch outer diameter X ½-inch thick full-length permanent casing and a full-length No. 11 all-thread center bar. The macropiles will be placed in two rows with 5-foot on-center spacing, with the first row vertical and the second row battered at 3V:1H to reduce lateral movement of the monolith.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

1. Project Information

The Ala Wai Watershed is located on the southeastern side of the island of Oahu, Hawaii(Figure 1-1) The watershed extends from the Ko'oalua Mountains to the nearshore water of Mamala Bay; including Makiki, Manoa, and Palolo Streams. The streams then flow to the Ala Wai Canal, a 2-mile-long man made waterway constructed in the 1920's to drain extensive coastal wetlands, thus allowing development of the Waikiki District.

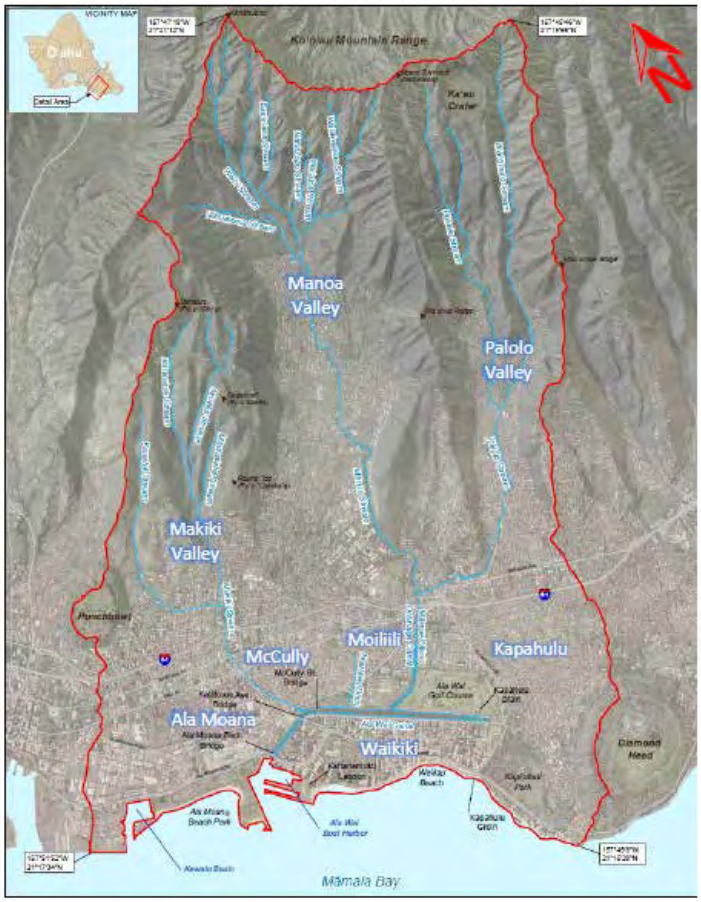

Figure 1-1. Overview of Ala Wai Watershed

2. Purpose

The purpose of this study is to reduce riverine flood risks in the Ala Wai Watershed. The purpose of the Structural Appendix is to construct various options for the floodwalls along the Makiki, Manoa, and Palolo Streams. Flooding has occurred within the watershed on multiple occasions, resulting in recorded property damages and health and safety risks. Analysis conducted in support of this project show that the 1-percent annual chance exceedance (ACE)

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

floodplain extends over approximately 1,358 acres of the watershed. The design of various walls throughout the Canal result in various degrees of reduced flooding. More information can be found in the Hydraulics Appendix (Appendix B).

3. Alternatives- GRR Measures

Individual measures were placed together in various arrays to accomplish flood reduction throughout the watershed. The combination of these measures created various alternatives that were then analyzed by H&H to prove that there were benefits and that there was exceptional flood risk reduction. Upon further analyses considering the project objectives and constraints, an array of alternative were developed:

Alternative 1 (Figure 3-1)	Storage Cornerstone
Alternative 2b (Figure 3-2)	Conveyance Cornerstone
Alternative 5 (Figure 3-3)	Hybrid
Alternative 5.3 (Figure 4-1)	Modified Hybrid Tentatively Selected Plan (TSP)

Table 3-1. List of Alternatives for consideration and TSP

Each Alternative is made up of individual measures as shown below:

Measures	Alternative 1	Alternative 2b	Alternative 5
Manoa District Park Multi Purpose Detention Basin	x		x
Manoa-Palolo Canal Floodwalls		x	x
Ala Wai Canal Floodwalls		x	x
Ala Wai Golf Course Multi-purpose Detention Basin	x		x
Makiki District Park Detention Basin	x	x	x
Woodlawn floodwall	x	x	x
Kanaha Floodwall	x	x	x
Koali Rd. Floodwall	x	x	x
Kaimuki Highschool	x	x	x

Figure 3-3.Alternative 5: Hybrid and TSP (in Order from left to right: Ala Wai Hybrid Detention Basin and Floodwall, Koali Rd Floodwall, Kaimuki Floodwall and Makiki Detention Basin, Manoa Detention Basin/Floodwall and Woodlawn Floodwalls)

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Table 3-3: Alternative Feature Summary

Measure	Structure Type[1]	Maximum Wall Height	Total Wall Length[1]	Maximum Excavation Depth	Number of Road Closures[2]	Number of Drainage Structures[2,3]
Kanaha Floodwall	L-wall on Macropiles	6 ft	2,200 ft	--	5	--
Makiki District Park Detention	I-wall	6 ft	1,200 lf	6 to 10 ft	--	2
Manoa Valley District Park Detention	I-wall	6 ft	1,580 ft	6 to 8 ft	--	2
Woodlawn Bridge Floodwall	L-wall on Macropiles	6 ft	1,625 ft	--	1	--
Koali Road Floodwall	L-wall on Macropiles	6 ft	2,485 ft	--	2	2
Kaimuki High School Floodwall (Alt 1 – ties into golf course berm)	L-wall on Macropiles[4] (1,700 ft) / I-wall (2,700 ft)	6 ft	4,400 ft	--	0 to 2	--
Ala Wai Golf Course Detention[5]	Berm	6 ft	5,640 to 10,665 ft	--	0 to 2	3
Ala Wai Canal Floodwall (Alt 2B / Alt 5)	L-wall on Macropiles[4] (20,005 / 19,960 ft) / I-wall (4,740 / 4,180 ft)	6 ft	24,745 / 24,140 ft	--	9 to 12	6 to 14
Kaimuki Extension of Ala Wai Canal Floodwall (Alt 2B / Alt 5)	L-wall on Macropiles[4] (1,030 / 1,800 ft) / I-wall (2,330 / 1,460 ft)	6 ft	3,260 / 3,660 ft	--	--	--
Makiki Floodwall[5]	U-wall on Macropiles[6]	6 ft	883 ft	--	4	1

[1] Berms to be 6 feet tall and have side slopes of 3H:1V with a 12-foot crown. I-walls to be 6 feet tall and have 18-foot of sheet pile (PZ22) embedment where the surrounding ground is flat and 24-foot of sheet pile embedment (PZ22) where the ground in front of the wall slopes down 3H:1V. L-walls to be 6 feet tall with a 12-foot-wide base supported on 16-inch diameter by 40 feet long cased macropiles with a 14-inch outer diameter X ½-inch thick full-length permanent casing and a full-length No. 11 all-thread center bar. The macropiles to be in two rows with 5-foot on-center spacing, with the first row vertical and the second row battered at 3V:1H.

[2] The length of the measure and the number of road closures and drainage structures may vary because of slight alignment changes between the alternatives.

[3] Indicates the number of inlet and outlet structures.

[4] The L-wall on Macropiles will be used adjacent to the stream (where erosion is more of a concern) or adjacent or nearby to the existing canal wall where damaging to the existing wall is a concern while the I-wall will be used in areas away from the stream (i.e., where there is flat ground) or away from the existing canal wall.

[5] An in-stream diversion/weir will be included in Alternative 1.

[6] The Makiki Floodwall was added during the evaluation of Alternative 5.2 but removed in Alternative 5.3 due to the induced damages created by its addition.

[6] U-walls assumed to extend 6 feet above existing Makiki canal walls/surrounding ground surface and be similar to L-walls, with the exception of the following changes: the base thickness is reduced; the base width will vary to match the existing channel width; and all macropiles assumed vertical (no batter).

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

4. TSP

Alternative 5 was selected for the TSP. This was completed by developing the Alternatives and completing a cost-benefit ratio and net benefits. It was established that Alternative 5 showed the most cost-effective option and was further investigated. The PDT then developed and optimized Alternative 5 to Alternative 5.1, 5.2, and 5.3. The TSP concluded to be Alternative 5.3 where some measures were eliminated (e.g., they could not be justified incrementally); the alignment of others were adjusted for optimization; and one measure was added to reduce induced damage considerations. Table 4-1 below shows the feature summary included in the TSP:

Table 4-1: TSP Feature Summary (Alternative 5.3)

Measure	Structure Type[1]	Maximum Height	Total Length	Number of Road Closures	Number of Drainage Structures[2]	Number of Flapgates[2]
Woodlawn Drive Floodwall	L-wall on Macropiles	6 ft	1,270 ft	1	--	--
Koali Road Floodwall	L-wall on Macropiles	6 ft	2,510 ft	2	2	2
Ala Wai Golf Course Detention	Berm (8,315 ft) L-wall on Macropiles[3] (1,861 ft)	6-9 ft	10,176 ft	1	5	5
Ala Wai Canal Floodwall[4]	J-wall on Macropiles[3] (17,125 ft) L-wall on Macropiles[3] (4,069 ft) Tieback I-Wall[3] (1,658 ft)	6 ft	22,852 ft	11	14	59

1. Berms assumed to be 6 to 9 feet tall and have side slopes of 3H:1V with a 12-foot crown. Taller berms planned at lower elevations of the Ala Wai Golf Course along the Ala Wai Canal.
   L-walls assumed to be 6 feet tall (except at Ala Wai Golf Course) with a 12-foot-wide X 40-inch-thick base supported on 16-inch diameter by 40 feet long cased macropiles with a 14-inch outer diameter X ½-inch thick full-length permanent casing and a full-length No. 11 all-thread center bar.
   L-walls at the Ala Wai Golf Course assumed to be 9 feet tall with a 13-foot-wide X 44-inch-thick base supported on 18-inch diameter by 50 feet long cased macropiles with a 16-inch outer diameter X ½-inch thick full-length permanent casing and a full-length No. 11 all-thread center bar. The macropiles to be in two rows with 5-foot on-center spacing, with the first row vertical and the second row battered at 6V:1H
   J-wall assumed to be the same design as 6-foot L-walls (i.e., same width, macropiles configuration, etc.), except the wall will include a 3-foot-tall concrete wall on the heel, with the 3-foot-deep area created between the front and rear walls backfilled with soil to create an elevated walkway along the Ala Wai Canal.
   Tieback I-wall) assumed to be toed into rock or extended 15 feet below the stream level with PZ30 sheet piles and 50-foot-long angled ties at 7 feet on-center with a continuous HP12X53 waler located 6 feet below the streambank crest.
2. Indicates the number of assumed outlet structures. It is assumed that existing storm drains larger than 36 inches will require a drainage structure (and positive closure). Smaller sizes may require drainage structures during future design phases.
3. J-wall on Macropiles assumed to be used primarily along the Ala Wai Canal (but also along the north side of the Manoa-Palolo to Date Street). L-wall on Macropiles assumed to be used adjacent to streams where visibility of the canal is not a major consideration and where erosion is more of a concern, while the I-wall assumed to be used in areas away from streams where there is flat ground and erosion is not a concern; however, there are no I-walls in the TSP (see explanation in one of bullet points below). The Tieback I-Wall assumed where space limitations and vibrations are major considerations and prevent the use of the other wall types (i.e., specifically planned on the north side of Manoa-Palolo Stream from Date Street to Kapiolani Boulevard).
4. The floodwall around the canal also accounts for four canoe closure structures.
   The Ala Wai Canal measure for the TSP is a combination of the floodwalls along the Ala Wai Canal and along the Manoa-Palolo (including at Kaimuki High School).

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

The primary changes from the Alternative 5 selected and described in Section 3 to the TSP presented in this section and report (Alternative 5.3) were the following:

Removal of the Kanaha Floodwall and the two detention basins (Makiki and Manoa) from consideration due to insufficient incremental benefits.

Conversion of all the L-wall along the main Ala Wai Canal to a J-wall to create an elevated 3-foot-tall walking path combined with a 3-foot-tall wall behind the existing canal wall. The 6-foot wall was deemed an unacceptable barrier to a cultural resource (the Ala Wai Canal). The elevated walkway created by the J-wall restored visual connection with the Ala Wai Canal (a major concern of the local residents), while also significantly reducing some of the safety concerns expressed with a 6-foot-tall wall with limited access between the canal and the nearby streets (i.e., the ability to get from the water side to the land side of the wall quickly due to only having limited wall penetrations for doors and gates in consideration of the short duration and minimal notice of flood events). In addition, the additional dead load created by the elevated 3-foot-tall walkway will help reduce lateral deflection of the pile cap, which will reduce potential impacts on the existing (sensitive) canal wall.

Conversion of the L-wall along the north bank of the Manoa-Palolo Stream from Date Street to Kapiolani Boulevard (which is considered part of the Ala Wai Canal Floodwall alignment) to a Tieback I-Wall due to insufficient space to construct the originally planned L-wall. The Tieback I-Wall requires less footprint for construction (equipment rides along installed sheet pile) and permanently (I-wall only requires 2 to 3 feet versus 12 feet for wide L-wall). In addition, the Giken technology allows sheet pile to be pushed hydraulically, instead of driven, reducing vibration concerns for nearby structures.

Conversion of the I-walls originally planned around the Kaimuki High School playing fields to L-walls for simplicity and continuity of the system (e.g., to avoid transition points since limited length of I-wall necessary and reduce the types of floodwalls used).

Extension of the Koali Road from the pedestrian bridge at Kaluawaa Street to St. Louis Drive due to lower ground elevations than originally assumed.

Taking of 2/3 structures (one residential structure, one commercial structure, and one small structure of indeterminate origin) immediately north of Kapiolani Boulevard due to their proximity to Manao-Palolo and the inability to construct a flood reduction system between the structures and the creek without permanent construction into the creek (and permanently impinging creek flow, which would cause damages upstream) and the inability to safely construct a wall around the structures (thereby excluding them from flood reduction system) due to the required sightlines at the intersection and the limited space for appropriate wall set-back from the street.

Increase in wall/levee heights at the Ala Wai Golf Course to increase detention volume.

The proposed alignments for each measure included in the TSP are included in Figure 4-1. Zoomed in views of the individual alignments are included in Figure 4-2 to Figure 4-4 for further reference. The types of risk reduction for each measure are shown in Figure 4-5.

5. Design Inputs.

Several design assumptions have been investigated and discussed to define the inputs data that were needed to design various wall types. The discussed design inputs included geotechnical data to define soil pressure, and the hydraulic data to define flood elevation. There was no updated survey completed to give exact elevations therefore the design “grade” is noted to be 0ft throughout the project and the top of wall for the wall design is +6ft. For the TSP some Wall heights were heightened to +9ft. Due to no survey data the structural design was based on assumptions and minimal profile information to assume the grade and slope used to determine wall placement in various regions of the project. The floodwall alignment should be evaluated during the design phase for optimum wall profile.

5.1. Soil Conditions

The soil conditions considered where based on the interpretation of the geology in the location. The soil conditions referenced in Attachment 1 of the Structural Appendix were incorporated into the various software used to design Structural Sheet Pile and Macro Piles. The grade height and slopes were assumed by the technical team due to no updated topography/survey.

More information can be found in the Geotechnical Appendix.

5.2. Hydraulic Data

The top of wall design parameter used for the wall designs throughout the project would be +6ft from grade (+9 for Ala Wai Golf Course Parking lot area in TSP) . More information on the hydraulic modeling and data can be provided in Hydraulic Appendix (Appendix B).

6. Assumptions

Due to lack of survey/topography/plans the types of walls were based on the assumed location of the walls. For the Structural Sheet Pile (SSP)/ I Wall there are two different design considerations. The first design assumes that the grade is equal on both side of the design wall. The other design assumption is that the I wall has a 3H:1V slope on one side of the wall. The wall analysis should be optimized during the PED phase with survey data.

Regarding the L-wall design, the slope was assumed by the technical team due to no profile information on multiple locations throughout the floodwall alignment. There could be room for optimization once there is more information on the topography where there is an L-Wall. The preliminary assumption is to design an L-wall where it is adjacent to the canal wall. Whereas the SSP/I-Wall is placed at a minimum of 15’ away from an existing wall or where there is enough soil on either side of the wall.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

7. Wall Types

7.1. SSP/I-walls

Structural Sheet Pile wall, commonly known at as an I-wall, consists of a driven, vibrated, or pushed row of interlocking vertical pile segments to form a continuous wall. For the sake of this report SSP wall and I-wall will be used interchangeably in this report. The wall may extend to the full height with sheet pile (Figure 7-1), or it may be constructed with sheet piling in the embedded depth and a monolithic CIP reinforced concrete wall in the exposed height (Figure 7-1, 7-2). For this design, with the concrete encasement, the SSP will be terminated at the top of wall elevation and should be further evaluated during the design phase to proceed with the optimum wall profile.

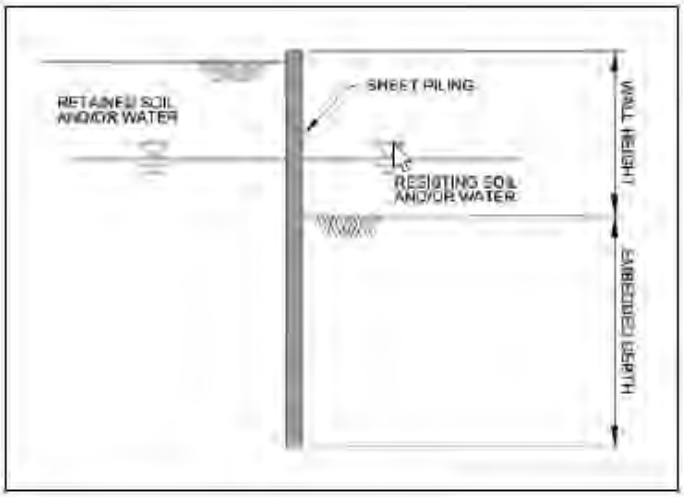

Figure 7-1. Typical Structural Sheet Pile Wall

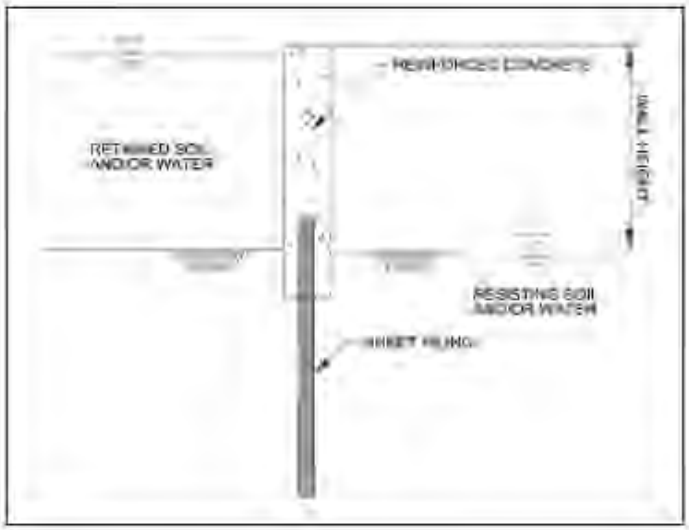

Figure 7-2. Sheet Pile Wall With Concrete Cap

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

The analysis and design of a cantilevered SSP (Structural Sheet Pile) wall is based on specification EM 1110-2-2502 “Floodwalls and other Hydraulic Retaining Walls”. Per the guidance walls constructed entirely with sheet piling will have leakage through the interlocks when water is retained above the ground surface. The designer will have to make sure that the interlocks need to be sealed properly above ground and that corrosion protection will need to be considered in the design of the SSP wall. Another option to contain leakage is to place concrete around the SSP at or below the frost line.

For preliminary measures the I -Wall structural design will only consider the SSP wall while the Concrete Design has not been done at this point of the design. For cost purposes the SSP wall will be encased with concrete from grade up to the top of wall elevation. The concrete encased SSP wall should be further evaluated in PED phase to achieve an optimum design. (See Figure 7-3). The reasoning for full depth sheet piling terminating at top of wall with concrete encasement is that it has the advantage of resilience by being able to transfer lateral loads through the sheet pile interlocks. Since the I wall is 6ft tall the typical I wall layout would include a concrete wall with SSP wall embedded due to the height of the wall. During the PED phase there should be further evaluation as to where the cut off the SSP wall should be.

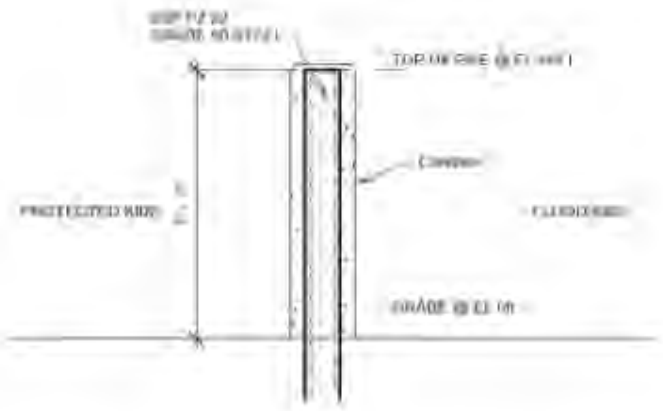

Figure 7-3. Concrete Encased SSP wall

Sheet pile walls are usually lower than 10 ft[1] of exposed height measured on the protected side of the wall. Conditions with soft soils and/or with downward slopes on the resisting side, such as a levee, reduce the overall height of the I-Wall. Because the design is in the feasibility stage it was decided to keep the wall maximum at 6ft due to multiple factors. In previous studies H&H would run a 20yr, 50 yr…and etc and then give the Structural Engineer a wall height. For this study the team determined it would be more beneficial to the project for H&H to run the hydraulic modeling considering a top of wall elevation of 6ft above grade throughout the watershed. The determination of the elevation was based on Figure 7-4 as well as considering other factors such as space constraints and maximum heights acceptable to the community in the area. For preliminary measures the height of 6ft seemed to be reasonable, but with further investigation the height may be reconsidered.

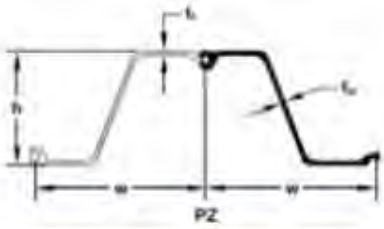
Figure 7-4. Maximum Wall Heights for Deformation Control of Cantilever Pile Walls Used for Floodwalls, Dam Walls, and Dam Crest Walls

According to EC 1110-2-6066 Design of I-Walls steel sheet piling used for I walls should conform to the Z-shaped hot-rolled Sections produced by various manufacturers. The interlock strength of the hot rolled sheet piling improves integrity during driving and allows forces to the redistributed laterally along the wall at changes in wall alignment, and in weak soil zones. For all the I wall Designs the SSP wall will be a PZ 22 with properties that can be seen in Figure 7-5 below.



SECTION	Width (w)	Height (h)	THICKNESS		Cross Sectional Area	WEIGHT		SECTION MODULUS		Moment of Inertia	COATING AREA	
			Flange	Web		Single Pile	Wall Area	Elastic	Plastic		Both Sides	Wall Surface

Figure 7-5. PZ 22 Section Properties

Please see Appendix 2 for the Structural Analysis.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

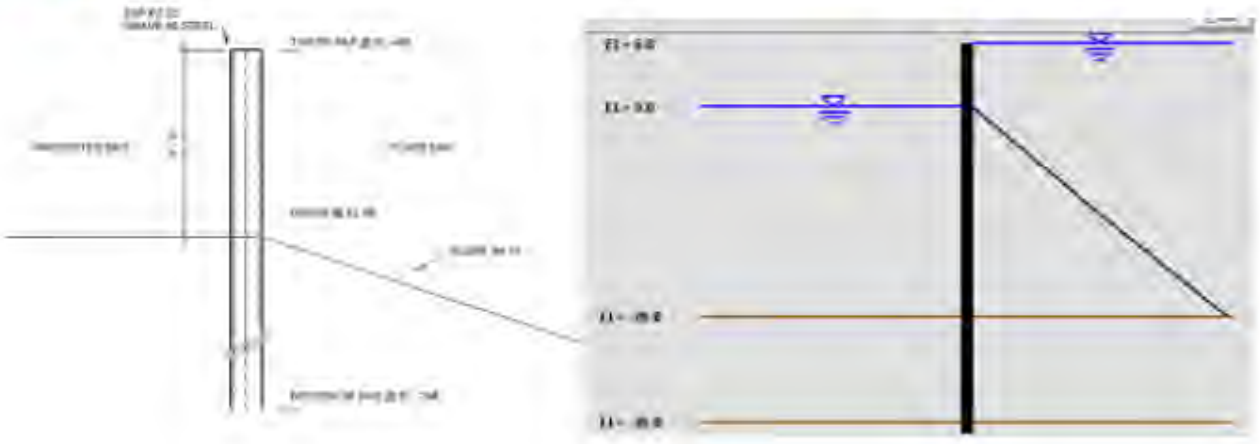

Figure 7-6. SSP Section with 3H:1V slope on Flood Side and CWALSHT Input

Figure 7-7. SSP Section with Grade @ 0ft on Flood Side and Protected Side and CWALSHT Input

Figure 7-6 and Figure 7-7 represent the section views of the two options of the SSP walls. For more information see Individual Measures Section 8. See Appendix 2 for CWALSHT OUTPUTS.

The benefits of I-wall is the ease of installation. The wall can be installed relatively close to existing structures with minimal excavation. in addition, the wall can be installed under wet conditions without the need for dewatering. [however, there will be some dewatering with the concrete installation] The disadvantages of using I walls include limited heights and deflections causing undesirable movement under service loadings.

7.2. L-Walls on Macropiles

According to EM 1110-2-2502 a concrete wall supported by driven piles or drilled shafts can be used when the minimum design requirements (bearing capacity, sliding, resultant location, or

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

settlement) cannot be achieved with a shallow-founded wall. It may also be useful if space limitations do not allow the base width required for a shallow-founded wall.

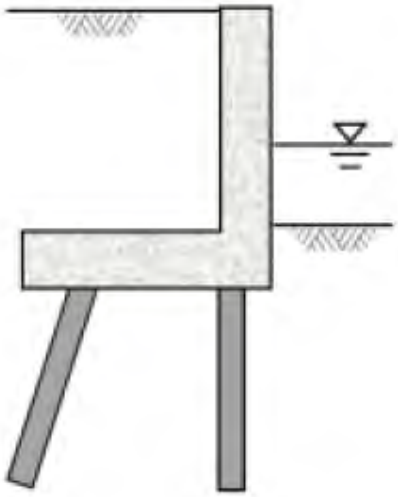

Figure 7-8. Typical L-Wall on Piles

Figure 7-8. shows the typical view of an L-Wall on piles. The wall stem and the deep foundations are designed to resist the induced moment, shear, and axial forces that are transmitted to the stem. There is typically sheet pile cutoff that is used to manage the seepage that occurs when the soil settles and creates a void or a zone of softer soil under the base. At this point of the design there was no sheet pile cut off designed.

The selection of the deep foundation system is a joint decision of the geotechnical and structural engineer that considers the site information and construction limitations. The selection of pile and the design and analysis of the deep foundation system is based on EM 1110-2-2906 and EM 1110-S-2502

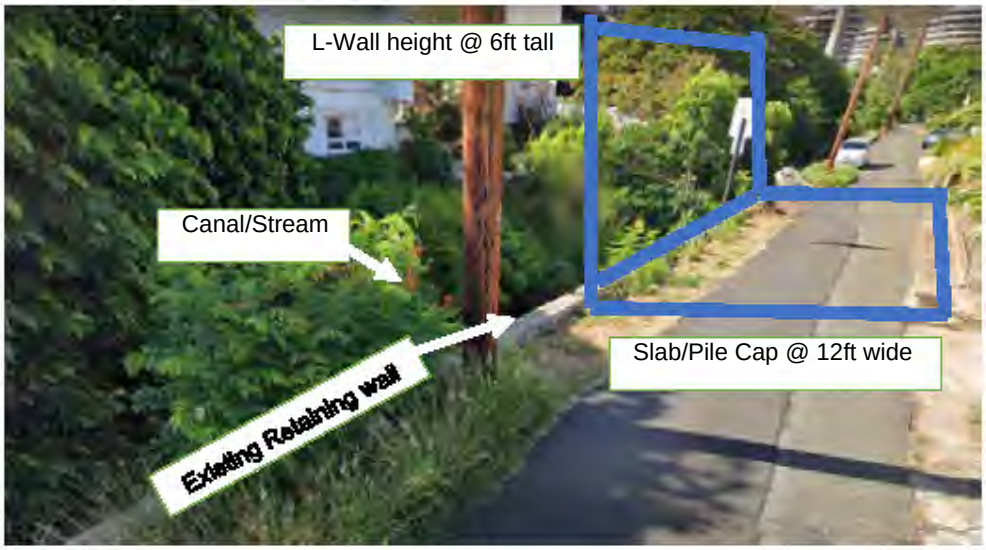

Figure 7-9. Typical L-Wall placement in respect to canal

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Figure 7-9. shows the L wall in proximity to the Canal. The decision to place the L wall adjacent to the stream instead of an I wall is due to the perceived enhanced stability against erosion as compared to I-walls. The top of wall is is at an elevation +6 from grade and the width of the concrete slab is 12 feet which is due to pile spacing based on EM 2502 and based on preliminary assumptions. With further investigation and use of topography/survey/plan views there may be a chance to optimize the width. Note that there should be an offset of 1 ft from the existing wall.

The L-wall will cannot sit directly on the retaining wall and will need to be placed a certain length away from the wall, therefore by moving forward with this design it was important to assume the placement is possible. Due to this space restriction along with other space restrictions such as real estate, overhead restrictions, the implementation of using macro-piles instead of driven piles was determined. Other factors influencing the selection of macropiles includes close pile proximity to existing structures, difficult geologic conditions, and vibration/noise sensitive areas. The drilling and grouting equipment used for macropile installation is relatively small and can be mobilized in restrictive areas that would prohibit the entry of conventional pile-installation equipment.

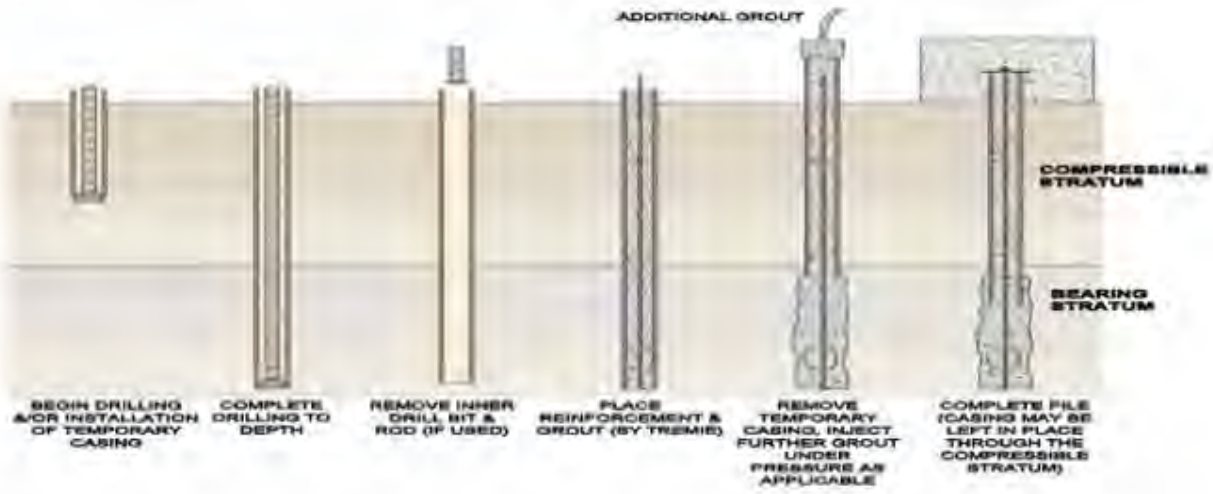

Figure 7-10. Example of Macropile placement[2]

A macropile is a small-diameter, drilled and grouted replacement pile that is typically reinforced[3]. A macropile is constructed by drilling a borehole, placing reinforcement, and grouting the hole. Macropiles are installed by methods that cause minimal disturbance to adjacent structures, soil, and the environment. They can be installed in access- restrictive environments and in all soil types and ground conditions. Macropiles can be installed at any angle below the horizontal using the same type of equipment used for ground anchor and grouting projects. Since the installation procedure causes minimal vibration and noise and can be used in conditions of low headroom, macropiles are often used to underpin existing

[2] Micropile Design and Construction Guidelines FHWA-SA-97-070, 2000
[3] Micropile Design and Construction Guidelines FHWA-SA-97-070, 2000

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

structures. Specialized drilling equipment is often required to install the macropiles from within existing basement facilities.

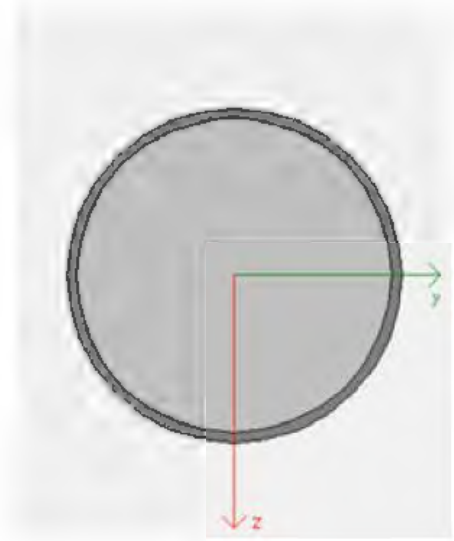

Figure 7-11. Typical Macro-pile cross section

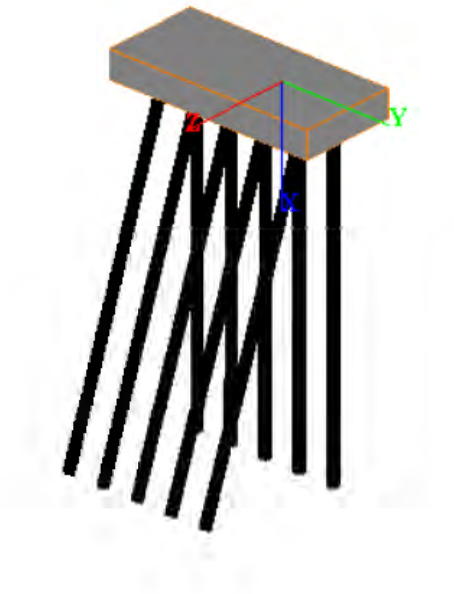

Figure 7-12. Group Ensoft Typical monolith for pile design

The pile design consisted of using the software Ensoft Group. The macropiles consist of a concrete shaft incased in a 16in diameter by ½in thick rounded HSS steel member (See Figure 7-10, 7-13). The ½" thickness of the pile was determined to help with corrosion but can be further investigated in the design phase. The concrete design of the L-wall has not been completed but concrete wall and slab/cap thicknesses were assumed based on engineering

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

judgement and minimum requirements as mentioned in EM 2502 (Figure 7-13). To see other structural consideration please refer to Attachment 3.

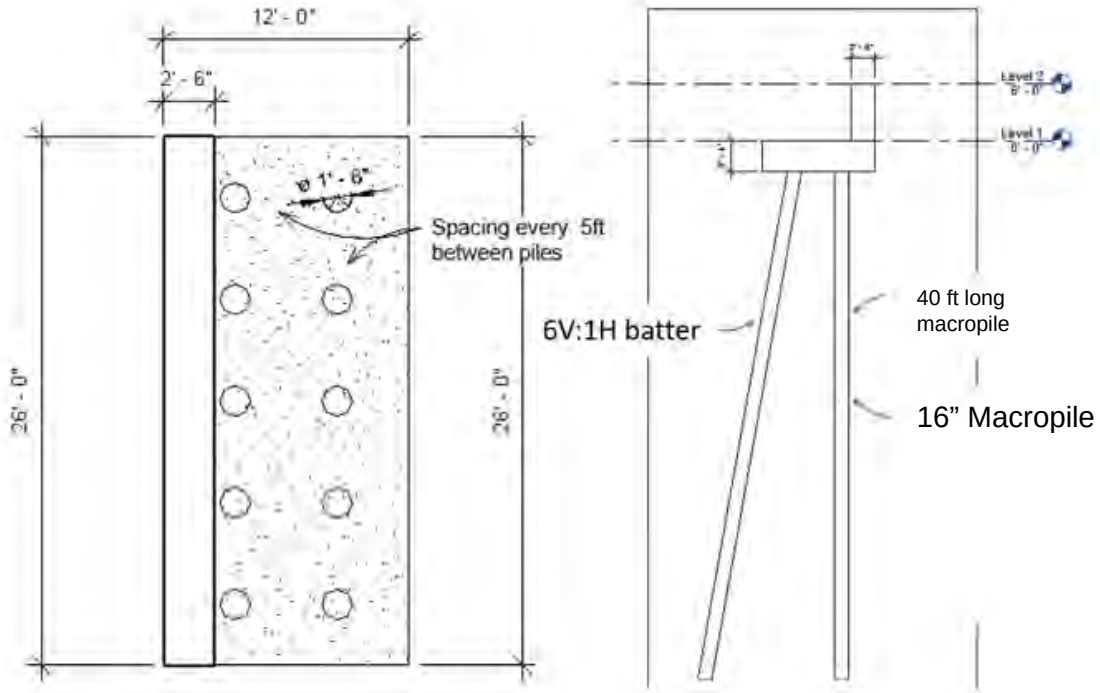

Figure 7-13. Preliminary L-wall on Macropiles Layout

With further investigation concrete may be replaced with grout as shown in Figure 7-10. The method of grouting is generally the most sensitive construction control over grout/ground bond capacity. Grout/ground bond capacity varies directly with the grouting method. The use of drill casing and reinforcement define sub-classifications. Grout/Grout placement can be further investigated in the design phase. For the purposes of the design the assumption of using concrete with f'c of 4000 psi was assumed for the macropile in Ensoft Group.

There are some risks associated with using the L-wall. As can be seen in Figure 7-9. there is limited amount of space and obstructions such as the utility pole. Since without updated topography/survey/plans the proximity of the wall may change and therefore will need to be revaluated.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

7.2.1. L-Wall 9ft tall wall edition to updated TSP

Figure 7-14 Area highlighted above showing L-Wall @ +9 ft

During the optimization of the TSP the observation of increasing the L Wall to +9 ft around the golf course (see Fig 7-14 above) was made in order to appease benefits in the area. The nine ft tall L-Wall will consist of a 2' – 8" thick wall stem and a 3'-8" thick pile cap (slab). The width of the pile cap was determined to be 13ft wide.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

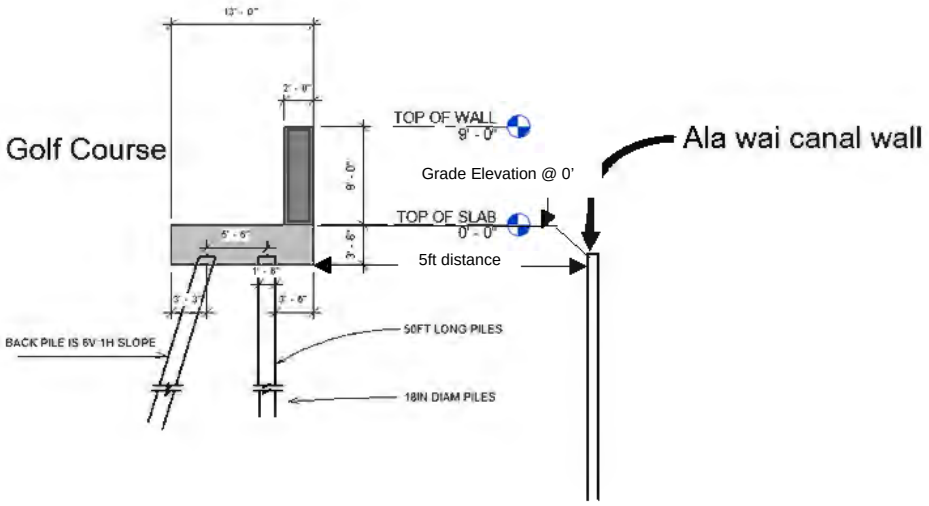

Figure 7-15 Typical Cross Section of +9ft tall L-Wall

The Pile diameter for the 9 ft wall was determined to be 18ft in Diameter and are 50ft long. This increase in diameter was made due to the different loading scenarios that could be presented. The steel pile will will have the same size steel rod and fill such as the 6ft tall wall. Theoretically there should be +6ft of water on the Ala Wai canal side with +9ft of water on the gold course side at the same time. This would conclude to a +3ft difference. This being said a load case scenario was made with +9ft water on the golf course side and +0 ft on the Canal side. This is a very conservative scenario and it should be noted that this load case would have to be further investigated during the PED phase if this wall type is chosen moving forward. During further optimization the wall stem may need to be moved more towards the center and the piles may need to be further optimized.

7.3. “J” Wall Type

The “J” Wall is a modification to the L wall. This Wall type is specifically placed along the Ala Wai Canal for the TSP.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

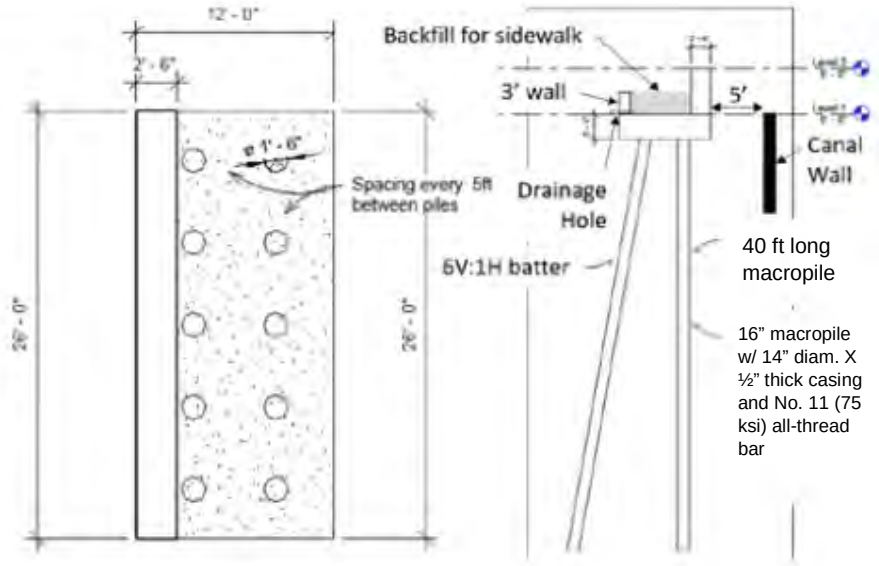

Figure 7-16 J wall Typical Cross section and layout

The J-Wall design is based on the L-wall design. The difference between the two is that there is 3' wall (as seen on Fig 7-16) on the end of the pile cap to place fill in. The purpose of this is to elevate the grade from 0 to +3ft. It is assumed that pedestrians can walk on top of the 3' fill in order to give visibility into the canal and not block visibility. Due to engineering judgement it is assumed it will be feasible if the L-Wall is feasible.

7.4. Tieback I-Wall

To further develop the TSP the implementation of an anchor wall design was considered due to the unique area and restraints presented. Along the Manoa-Palolo Stream from Date Street to Kapiolani Boulevard tall buildings were situated very close to proposed alignment. This led to an obstacle on evaluating wall type and feasibility. The typical I wall design was not ideal due to the sharp slope from where the alignment would be set to the canal. Due to minimum real estate and buildings close to the alignment a Tieback I-Wall was considered.

Figure 7-17 Ariel of canal and buildings in close vicinity (blue line)

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

As seen above (Fig 7-17) the area where the TieBack I-Wall was to be implemented is close to the building. The constructability of the wall would be achieved by the “Giken Method” of drilling and the the wall would be anchored. The Anchorage/tie back was assumed to be 50’ long and placed every 7 ft o.c. The anchors were assumed to be soil anchors and they would be place 6 ft below grade and attached to a HP 12 X 53 waler. The concrete portion of the wall would be 6ft tall encasing the SSP (PZ 30) and is assumed to be 2’ 8”. This The anchorage would be able to be achieved due to the buildings assuming to have no basements. For more information of the wall please see below (Fig 7-18).

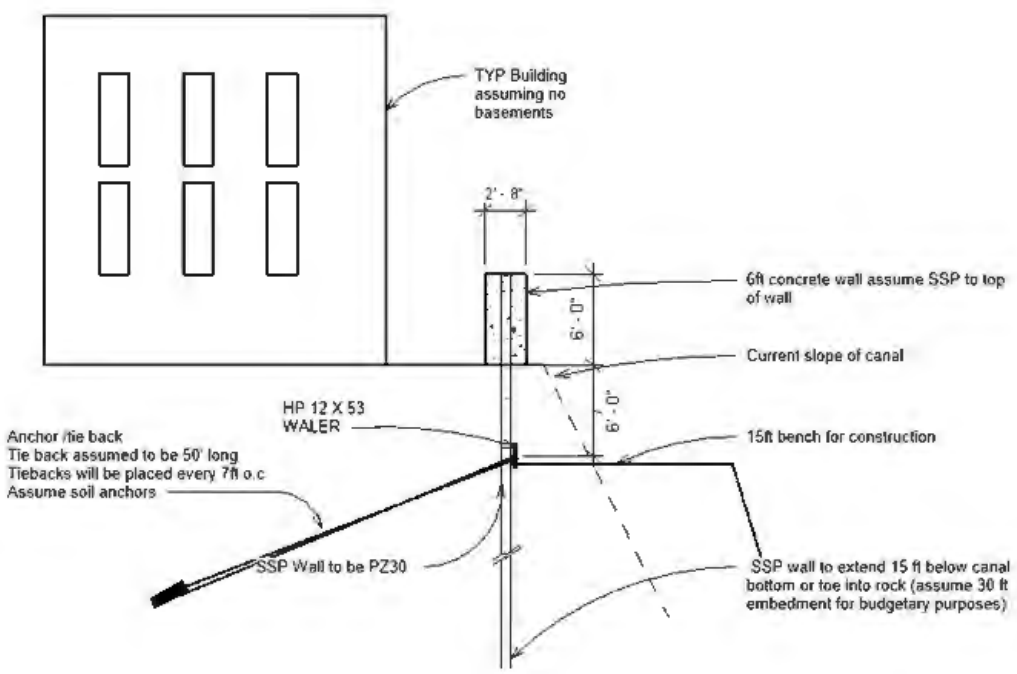

Figure 7-18 Tie-Back I Wall

The design of the wall is based on engineering judgement and past projects. Since there are many unknowns such as elevation difference between top of canal and bottom of canal, and slope there will need to be much investigation and survey needed to confirm this design is feasible. The constructability of this wall should be further investigated during the PED phase due to the possibility of not being able to drive the SSP wall due to the proximity of the buildings.

7.5. “U” Wall Type (Eliminated from TSP)

The “U” Wall was to be located along from the Ala Wai Canal to Fern Street. Due to not being able to build on top of existing walls the design would consist of designing within the extents of the canal. As can be seen on Figure 7-19, there are areas of the canal that had a natural bottom. The as-built drawings presented to the PDT from the City of Honolulu showed a concrete slab, which conflicted with other areas of the canal shown below on Figure 7-19. Due

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

to this conflict the approach to design a u-shaped wall with macropiles was determined to consider all possible existing conditions of the canal.

Figure 7-19 View of Canal from Fern Street.

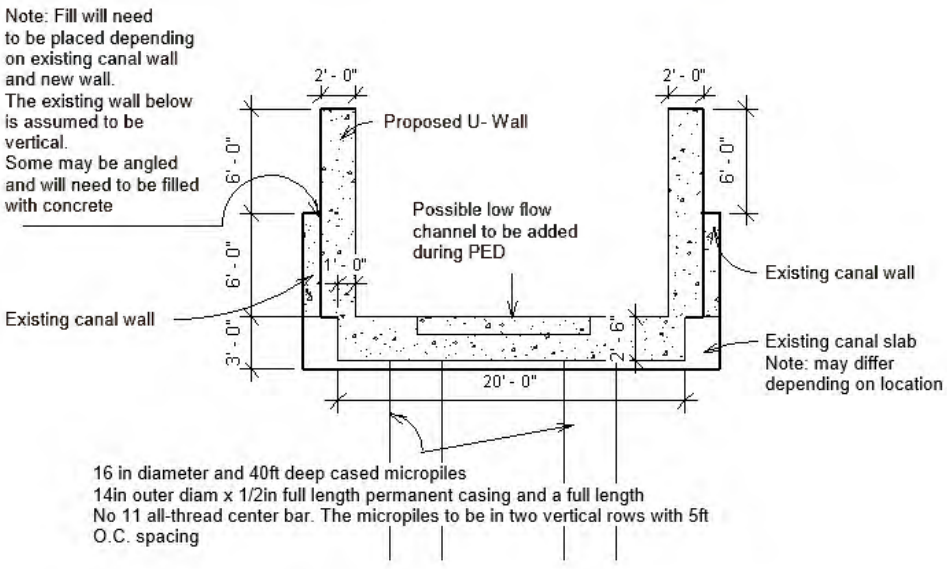

Figure 7-20 Typical Cross Section of "U" Wall

As seen on Figure 7-20 the design of the U-Wall would consist of placing cast in place concrete against the existing walls and designing a cast-in-place slab connected to macropiles. There is a possibility of not implementing macropiles, but that would have to be further investigated through PED.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Figure 7-21 Assumed Constructability of U-Wall based on other canal Construction as seen above

Constructability was discussed through the PDT and there was assumptions on how the wall would be built. As seen in Figure 7-21 for reference the assumption would consist of small lengths of the wall being constructed as well as maintaining the current canal by keeping half of it active as the other half is being constructed. The Makiki Floodwall was further on eliminated from the TSP due to induced damages.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

7.6. Other Design Alternatives

7.6.1. T wall Design

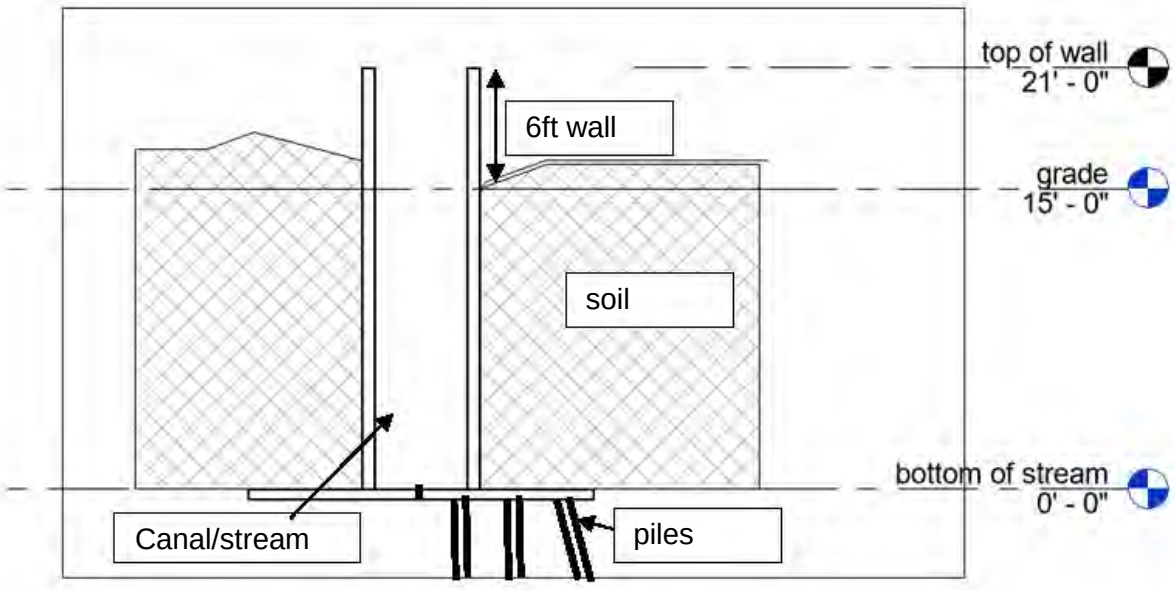

Figure 7-22. T wall on Piles cross section

A T-wall with piles (Figure 7-22) was considered in lieu of the L-wall on macropiles. There were too many unknowns when considering this wall type. Since there was no updated survey the topography of each stream could not be assumed. Some streams were deeper than others so the T-wall concrete and pile design would differ based on the depth of inside the canal/stream. The cost of removing fill to place the cap and piles was assumed to be more expensive compared to the L-wall with macropiles already sitting on grade. The construction costs were also assumed to be more expensive than that assumed on the L-wall on macropiles. Due to these considerations the T-wall never went past a concept level of design.

7.6.2. Other Cantilever wall types

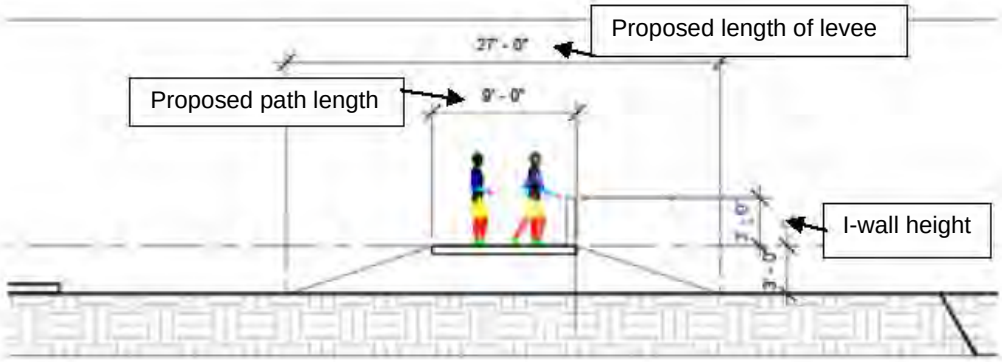

Figure 7-23. 3' I-Wall on Levee

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Other cantilever wall types were considered such as a 3ft I wall on a levee (Figure 7-23) instead of a 6ft cantilever wall. The benefit of this would be for locals to use this as recreational area and be able to use the levee as a path and still look over the wall. The reasoning for this wall type not being further investigated is because of the assumption of unsuitable soils, and not having updated topography to ensure there is enough space for the levee. Also, the I-wall being at the edge of the levee is not ideal so the consideration of offsetting the wall would have to be made. Since there is no insurance there would be space to lengthen the path on top of the levee to offset the wall and due to time restraints, this concept was not further investigated.

7.6.3. Ala Wai Canal Walk Flood protection

Figure 7-24. Chicago Shoreline Terraced Wall cross section and Shoreline implementation in Chicago

A concrete terraced walkway consisting of a concrete stepped walkway being help by macropiles, sheet pile, and stone fill was considered at the concept level (See Figure 7-24). This specific wall type would be applicable at the Ala Wai Canal where the population and tourism are more present. This flood protection would be disguised as a stepped walkway for tourists.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

The reasoning why this concept did not move forward was due to costs compared to an I-wall and L-wall.

8. Other Structural Design Elements

8.1. Gate design

The gate design throughout the project was assumed to be a double swing gate. This assumption is based on the perception that most of the Gate structures will be on roads. Therefore, designing a single swing gate may not be realistic. For preliminary studies the structural engineer is assuming a double swing gate as can be seen in Figure 8-1.

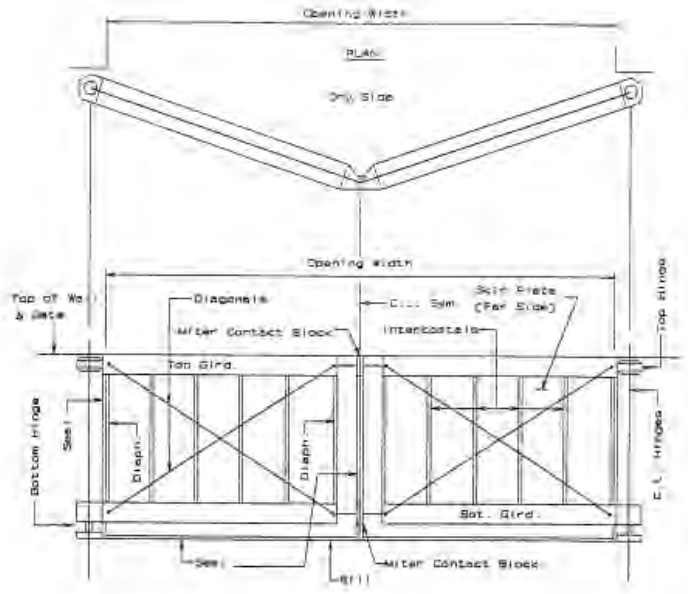

Figure 8-1. Example of a Double Swing Gate

Some locations can be further investigated and the gate type can be reduced to a single swing gate due to length of road closure as seen below in Figure 8-2.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

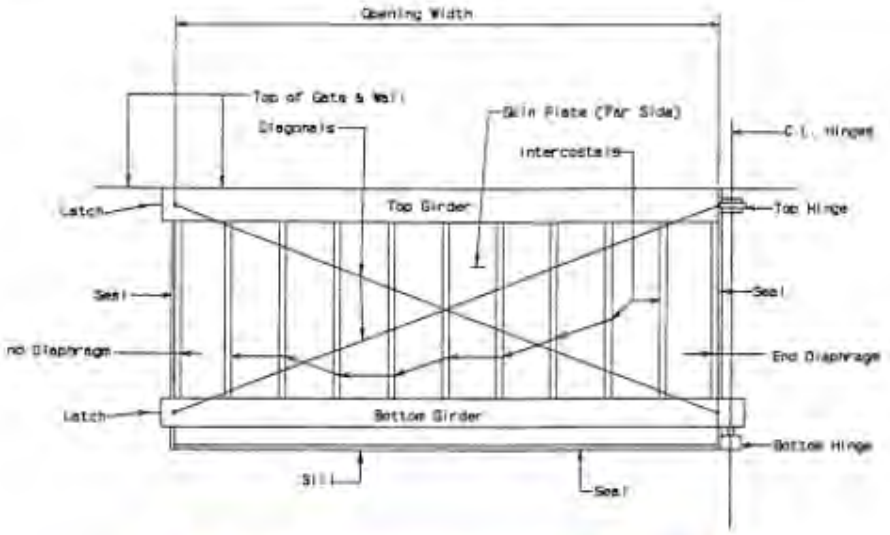

Figure 8-2. Example of a Single Swing Gate

Location	No. of Gates
Woodlawn	1
Ala Wai	9 to 12
Koali Rd	2
Kahaha Rd	5
Kaimuki High School	0 to 2

Table 8-1 Gates per Location

8.2. Weir Design

There is a Weir design to be considered for this project. The location of the weir will be along stream that is located to the left of the Ala Wai Golf Course. At this stage of the project there is no design for the Weir. There were only conceptual considerations provided to cost.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

9. Individual Measures

9.1. Ala Wai Floodwalls

9.1.1. Alternative 2b I-Wall and L-wall on Macropiles

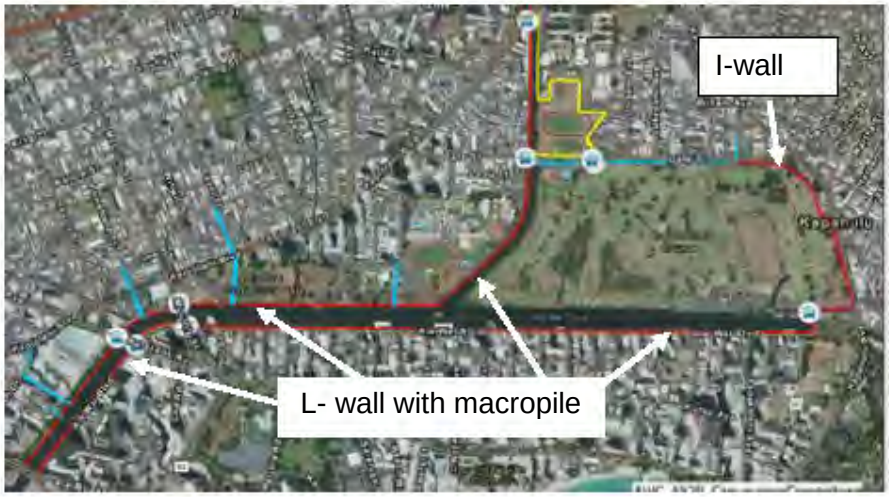

Figure 9-1.Aerial view of Ala Wai Floodwalls Alt 2B

Figure 9-2. I-wall location regarding Ala Wai Floodwalls

For Alternative 2b the approximate length of I wall is 4740 ft and the approximate length of L-wall with macropiles is 20005 ft (See Figure 9-1). The location of the I wall is along the golf course as well the along Kapahulu Ave (Figure 9-2).

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

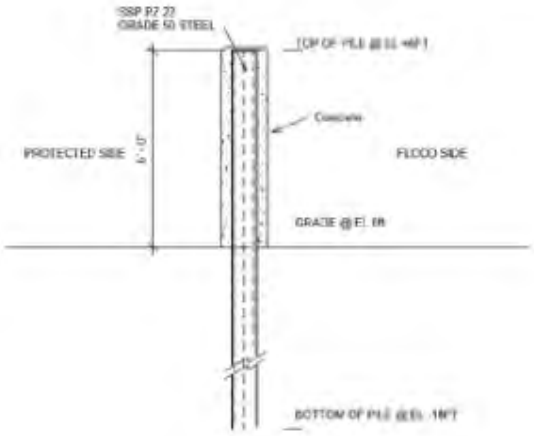

Figure 9-3. I wall Cross section for Ala Wai Floodwalls

The I-wall is composed of a PZ22 SSP wall at a top of wall elevation of +6ft and an embedment depth of -18ft. This wall will also be encased with concrete for architectural affects (Figure 9-3). Please see section 7.1 on more information I-walls. The proximity of the I wall in respect to the street has not been determined due to no plans being provided. This being said there was no assumption of a surcharge load on the CWALSHT design. Further investigation will have to clarify the grade and the proximity of the I-wall to nearby roads/structures that can affect the design.

Figure 9-4. L wall location within Ala Wai Floodwalls

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

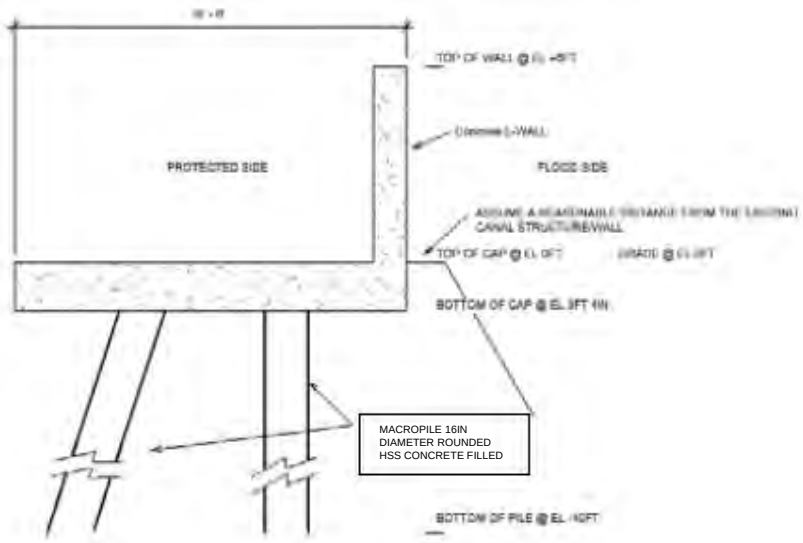

Figure 9-5 Typical Cross section of L-wall on macropiles

The L-Wall locations can be seen in Figure 9-1, 9-4 and 9-7. The L-walls will run down the canal to the Kahanamoku Lagoon. This wall is feasible with the assumption that there is enough space to place the L-wall all along the canal. A typical cross section of the L-wall on macropiles can be seen on Figure 9-5. See Appendix 3 for the pile design information.

9.1.2. Alternative 5

Figure 9-6 Ariel View of Ala Wai Floodwalls Alternative 5

For Alternative 5 the approximate length of a 6ft tall I wall is 4180 ft and the approximate length of a 6 ft tall L-wall with macropiles is 19960 ft (See Figure 9-4). The location of the I wall is along the gold course as well the along Kapahulu Ave (Figure 9-2). The difference between the two alternatives is that there is a detention basin along Alternative 5.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

9.1.3. TSP (Alternative 5.3)

Figure 9-7 TSP ALA WAI CANAL AREA

For Alternative 5.3 (TSP) the approximate length for the Ala Wai Golf Course is 1,891 ft of L-walls on macropile. This length includes both the six ft and nine ft walls. For the Ala Wai Canal Floodwall there will be a total length of 17,125ft of J-Wall, 4,069 ft of L-wall on Macropiles, and 1,658 ft consisting of the Tieback I-Wall. For more information on the various wall types please see Section 7.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

9.1.4. Structural Considerations

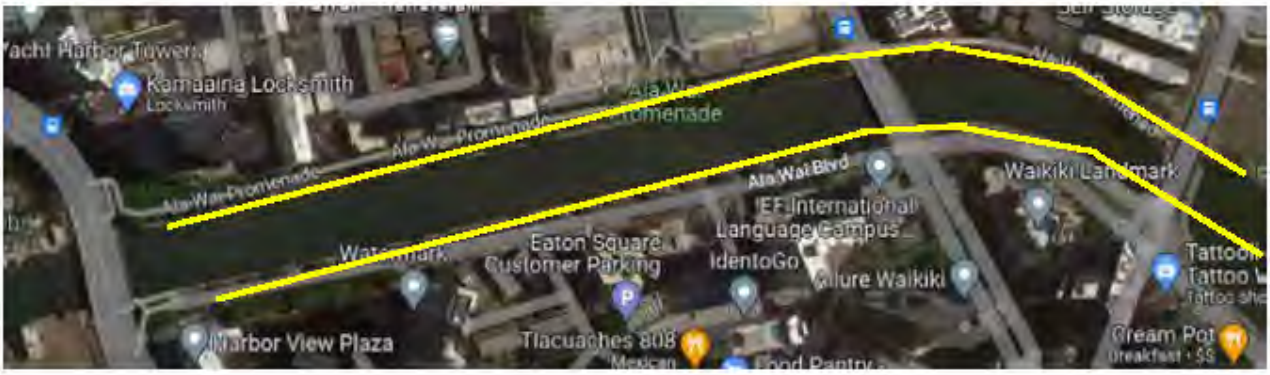

Figure 9-8. L-wall proximity

As mentioned in Section 8.1 there were a lot of assumptions made on the Design. Further investigation is needed when it comes to the wall design. The risk of assuming location without any plans can affect the design. Especially the section (marked in yellow) along the Ala Wai Bld and Promenade as seen in Figure 9-8. There may be obstructions that can potentially affect the design and must be clarified and resolved.

For the Tie-back I Wall design there were many factors that were assumed to put together a design for feasibility. Since there was no survey or cross section to use as reference the design is subject to change.

9.2. Kaimuki Highschool

Figure 9-9. Aerial View of Kaimuki Highschool Alternatives 1, 2b, 5

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Alternative 2b, and 5 will include a 6ft tall L-wall with macropile section that is 1030 ft, and 1800 ft long respectfully, and of 2330 ft and 1460 ft respectfully for the I wall portion of the area; also 6ft tall. Figure 9-9 shows the L-wall along the stream and the I wall in the High School track/park area.

Alternative 1 is very similar to Alternative 2b and 5 except it will tie into the golf course berm. This alternative includes 2,700 ft of a 6ft tall I wall and 1,700 ft of a 6ft tall L-wall with macropiles. Please see Section 7 on more information on I-walls and L-walls.

9.2.1. Structural Considerations

For this portion of the project the concern of space with the L-wall portion of the alignment needs to be explored more and there will need to be a survey conducted and proper cross sections given to the structural engineer. Below in Figure 9-10 there are a few initial possible obstructions such as a the buildings and the roads. There will need to be more investigation in this particular area to make sure the L-Wall is feasible.

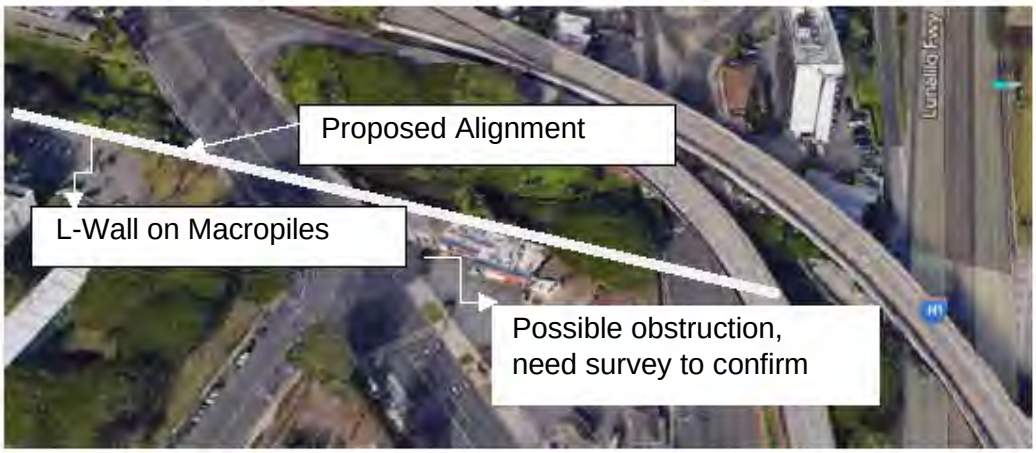

Figure 9-10. Section of L-wall for Kaimuki School Section. Possible obstruction

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

9.3. Woodlawn Floodwall

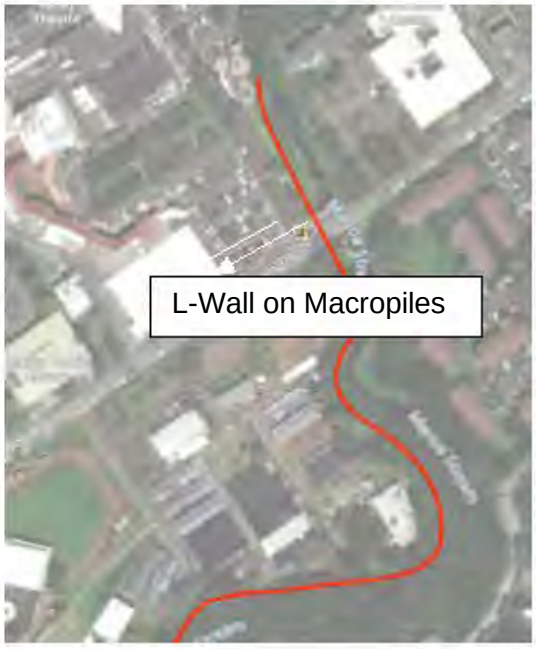

Figure 9-11. Aerial View of Woodlawn

The Woodlawn Floodwall span 1,270 ft and considers an L-wall with macropiles only. At this stage of the design the I wall was not considered because there are too many unknowns. For future exploration the possibility of changing some lengths of wall to I-walls may be possible.

9.3.1. Structural Considerations

When looking into the southern portion of the alignment past the bridge; there may need to be some further investigation regarding wall type, and construction. As one can see in Figure 9-12, the canal becomes more narrow and steep and there is not much space for construction material going further into the canal. An L-wall on macropiles was considered due to the possible stability issues the I-wall may bring. Confirmation through survey and updated soil information can confirm feasibility on wall type in future design work. For more information on the L-wall with Macropiles wall type please see Section 7.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Figure 9-12 Woodlawn looking south from the bridge

9.4. Makiki District Park and Manoa District Park

Makiki District Park and Manoa District Park will have the same concept for their wall design. Makiki Park wall alignment will span 1,200 ft and will be an I wall. The Manoa Park wall alignment will span 1,580 ft and will also be an I wall. These walls will be six ft tall. The protected side will be straight grade while the flood side will be assumed to have a slope of 3V:1H as can be seen in Figure 9-13. For more information on the I Wall design please see Section 7.

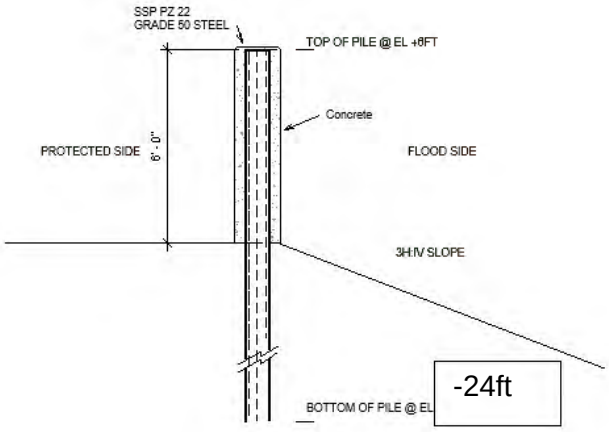

Figure 9-13.I wall Cross section for Manoa and Makiki District Parks

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

9.4.1. Structural Considerations.

Figure 9-14 Makiki Park

Figure 9-15. Manoa Park

As can be seen above Makiki Park and Manoa Park both have enough area where one can consider a few wall types and combination of wall types. For example, with further investigation, one can design an SSP wall and have a slope embankment cover most of the SSP wall so the community can walk and use the area for seating. A rendition was made below (Figure 9-15) to show an example of that. If something such as the below rendition is considered, then the design of the SSP would need to be reevaluated in further design work.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Figure 9-16. Sloped Embankment w/ SSP and Concrete Cap

9.5. Kanaha Floodwall Type and Structural Considerations

Figure 9-17. Aerial View Kanaha Floodwall

The Kanaha Floodwall includes 2,200 ft of 6ft tall L-wall with macropiles. Figure 9-17 shows the area in which this floodwall will be located along the red line. As one can see below Figure 9-18 the area is very urban and real-estate will be an issue along this alignment. Further investigation may result to considering another wall type that is feasible. At this stage of the project there were no cross section provided to confirm location of neighboring buildings so the L-Wall was assumed. For more information on L-walls please refer to Section 7.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Figure 9-18. Kanaha Floodwall location

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

9.6. Koali Road Floodwall

Koali Rd floodwall includes 2,510 ft of L-wall with macropiles and is set at 6ft tall. This wall type was considered due to the alignment being along a stream.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

9.6.1. Structural Considerations

Further investigation must be considered before moving forward with the L wall design including a survey being done so that proper cross sections can be obtained. The cross section assumes that the wall type can be placed on the existing road. Before the design is to be considered it will need to be confirmed that the road can be designed over it or that the community knows that road will no longer be accessible.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Appendix 1

Soil Conditions

1.1.1. Woodlawn:

0.0-7.5 ft Clayey SILT (MH) - Medium stiff to stiff with sand and gravel (may include cobbles)

Blow Counts: 15 (ranges from 10-35)
Moist Unit Weight, g: 105 pcf (ranges from 95-120 pcf)
Effective (Long Term) Friction Angle, f': 30 degrees (ranges from 25-35 degrees)
Effective (Long Term) Cohesion, c': 100 psf (ranges from 0-200 psf)
Total (Short Term) Friction Angle, f: 20 degrees (ranges from 15-30 degrees)
Total (Short Term) Cohesion, c: 900 psf (ranges from 750-1500 psf)

7.5-14.0 ft Silty SAND (SM) - Loose to dense, with gravel (may include cobbles)

Blow Counts: 10 (ranges from 5-30)
Moist Unit Weight, g: 105 pcf (ranges from 95-125 pcf)
Effective (Long Term) Friction Angle, f': 30 degrees (ranges from 30-35 degrees)
Effective (Long Term) Cohesion, c': 100 psf (ranges from 0-500 psf)
Total (Short Term) Friction Angle, f: 30 degrees (ranges from 25-37 degrees)
Total (Short Term) Cohesion, c: 100 psf (ranges from 500-1,000 psf)

14.0-20.5 ft Silty GRAVEL (GM) - Medium dense to dense, with sand, cobbles, and boulders

Blow Counts: 12 (ranges from 10-30)
Moist Unit Weight, g: 110 pcf (ranges from 105-130 pcf)
Effective (Long Term) Friction Angle, f': 30 degrees (ranges from 30-35 degrees)
Effective (Long Term) Cohesion, c': 100 psf (ranges from 100-500 psf)
Total (Short Term) Friction Angle, f: 30 degrees (ranges from 30-35 degrees)
Total (Short Term) Cohesion, c: 100 psf (ranges from 100-500 psf)

> 20.5 ft Weathered basalt

Groundwater is assumed to be at 8.5 feet.

Drilling info for Woodlawn: 25 ft of soil and 15 ft of rock (basalt), with difficult drilling due to cobbles and boulders below

1.1.2. Manoa and Maikiki

0.0-20.0 ft Alluvial Deposits - Clayey SILT (MH), Sandy Silt (ML, MH), and Silty Sand (SM) - Soft, loose

Blow Counts: 1 (ranges from 1-4)
Moist Unit Weight, g: 100 pcf (ranges from 85-105 pcf)
EVALUATE SCENARIO 1
Effective (Long Term) Friction Angle, f': 20 degrees (ranges from 15-25 degrees)
Effective (Long Term) Cohesion, c': 100 psf (ranges from 0-500 psf)
Total (Short Term) Friction Angle, f: 10 degrees (ranges from 5-20 degrees)

Total (Short Term) Cohesion, c: 500 psf (ranges from 250-750 psf)

EVALUATE SCENARIO 2

Effective (Long Term) Friction Angle, f': 26 degrees (ranges from 25-30 degrees)
Effective (Long Term) Cohesion, c': 100 psf (ranges from 0-200 psf)
Total (Short Term) Friction Angle, f': 26 degrees (ranges from 25-30 degrees)
Total (Short Term) Cohesion, c': 100 psf (ranges from 0-200 psf)

20.0-30.0 ft Alluvial Deposits - Silty Gravelly SAND (SP) and Sandy Gravel (SP) - Very loose to loose, saturated z

Moist Unit Weight, g: 110 pcf (ranges from 100-120 pcf)
Effective (Long Term) Friction Angle, f': 26 degrees (ranges from 25-30 degrees)
Effective (Long Term) Cohesion, c': 100 psf (ranges from 0-200 psf)
Total (Short Term) Friction Angle, f': 26 degrees (ranges from 25-30 degrees)
Total (Short Term) Cohesion, c': 100 psf (ranges from 0-200 psf)

30.0-50.0 ft Sandy SILT (MH) - Soft

Blow Counts: 1 (ranges from 1-3)
Moist Unit Weight, g: 95 pcf (ranges from 90-105 pcf)
Effective (Long Term) Friction Angle, f': 20 degrees (ranges from 15-25 degrees)
Effective (Long Term) Cohesion, c': 100 psf (ranges from 0-500 psf)
Total (Short Term) Friction Angle, f: 10 degrees (ranges from 5-20 degrees)
Total (Short Term) Cohesion, c: 500 psf (ranges from 250-750 psf)

1.2. Drilling Conditions

1.2.1. Kanaha

Kanaha: 740 lf with 20 ft soil and 20 rock (cinders) and 1,460 lf with 32.5 ft soil and 7.5 ft rock (cinders).

1.2.2. Kaoli

Koali rd: 515 lf of 29 ft of cobbly/boulder clay (difficult drilling) and 11 ft of basalt / 555 lf of 30 ft of cobbly/boulder clay (difficult drilling) and 10 ft of rock (basalt) / 1415 lf of 35 ft of soil (difficult drilling) and 5 ft of boulders (difficult drilling).

1.2.3. Kaimuki

Kaimuki: 20 ft of soil and 20 ft of coral for sections immediately adjacent to the stream and 40 ft of soil everywhere else with the lower 20 ft consisting of difficult drilling.

EM 1110-2-2502 Floodwalls and Other Hydraulic Retaining Structures

Design Summary:

The following calculations detail all load case for preliminary design for the L wall at +6ft Geometric parameters, elevations, and calculations of preliminary values, such as pile spacing can be found in the summary sheet.

Design Assumptions:

1. In this current iteration of the design, settlement loads are still preliminary and subject to change pending review

2. Additionally, the foundation deany uplift due to checks being preliminary

U.S. ARMY CORPS OF ENGINEERS - CHICAGO DISTRICT

Project: ALA WAI

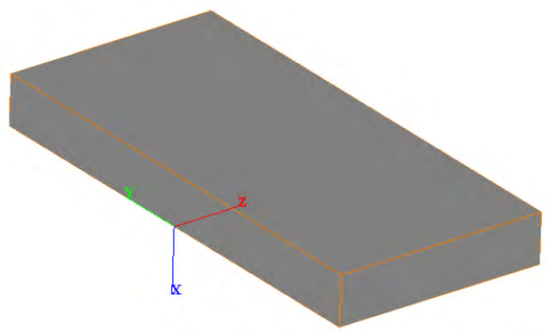
Subject: **Determination of Pile Foundation Loads (Land Bridge Monoliths)**

DOR: K.Sitko **Updated:** Oct-23 **Checker:** **Date:**

MONOLITH PARAMETERS

Geometric Parameters used for Design

T/Pile Cap EL	0	ft
B/Pile Cap EL	-3.5	ft
Design Elevation	6	ft
Width of Monolith	13	ft
Length to Wall Stem FS	26	ft
Length to Sheetpile (From Flood Side)	0	ft
Total Length of Pile Cap	26	ft
Thickness of Wall Stem	2.667	ft
Thickness of Pile Cap	3.667	ft
Grade	0	ft



change the inputs for pressures

PERMANENT LOADS, LP

Dead Loads, D

All permanant loads due to structure weight

Concete Weight, γ_c: 150 pcf

	Length (ft)	Width/Height (ft)	Area (ft^2)	Thickness (ft)	Volume (ft^3)
Pile Cap	13	26	338	3.667	1239.4

Load		Fx [kip]	Fy [kip]	Fz [kip]	x [ft]	y [ft]	z [ft]	Mx [kip-ft]	My [kip-ft]	Mz [kip-ft]
Pile Cap		185.92					13.00		2416.92	
	0	0.00					26.00		0.00	
Total		**185.92**							**2416.92**	

Vertical Earth Pressure, EV

Since there is no soil on top the floodwall structure, the vertical pressure due to soil is 0

Lateral Earth Pressure, EH

$\phi = \phi' =$	28	
$\theta =$	90	
$\delta =$	0	
$K_O =$	0.5305	
$K_P =$	2.7698	
(Amended) $K_P =$	1.119648879	
$K_A =$	0.3610	
saturated unit weight soil, Y_{sat}:	#REF!	pcf
submerged unit weight soil, Y':	#REF!	pcf
top of soil EL. =	2.00	ft
bot. of base EL. =	-3.50	ft
h =	5.50	ft
length of wall:	13	ft

Submerged earth pressures will be used on the floodside during flood events.

Saturated earth pressures will be used on the landside

Per EM 2502 Section II 3-4b, the passive pressure is adjusted to be 1/2 the calculate passive pressure due to the settlement being relatively small compared to what is needed to develop full passive resistance

Surface Soils have been revised to be sand per Geotechnical Engineers. This will be included/revised Post-35%

$$K_P = \frac{1 + \sin\phi}{1 - \sin\phi} = \tan^2\left(45° + \frac{\phi}{2}\right) = \frac{1}{K_A}$$

$$P_{PH} = \frac{1}{2} K_P \gamma' h^2 + 2c\sqrt{K_P}\, h$$

$$P_A = \frac{1}{2} \gamma' \frac{1}{\sin\theta \cos\delta} K_A h^2$$

Passive/Active Pressure
EM 1110-2-2502 [3-20]

Passive Pressure
EM 1110-2-2502 [3-21]

Active Pressure
EM 1110-2-2502 [3-11]

Load	Fx [kip]	Fy [kip]	Fz [kip]	x [ft]	y [ft]	z [ft]	Mx [kip-ft]	My [kip-ft]	Mz [kip-ft]
EH_{FS_dry}									
EH_{PS_dry}									
EH_{FS_sat}			0.00	1.83				0	
EH_{PS_sat}			0.00	1.83				0	
EH_{FS_sub}			0.00	1.83				0	
EH_{PS_sub}			0.00	1.83				0	

Downdrag, DD

Downdrag loads are are calculated by analyzing the negative skin friction and Settlement Induced Bending (SIB) (for battered piles) caused by the settlement of soil on deep pile foundations. This negative skin friction will only be applicable in the calculation of pile stresses and not pile capacity, however, SIB will be applied to all load cases. The value of these loads will be provided by the Geotechnical Engineer

TEMPORARY LOADS, LT

Hydrostatic Loads, Hs

Weight of Water, γ_w:	64 pcf	Heel Length of Wall:	0 ft	T/Pile Cap:	0 ft
Pile Cap Length:	26 ft	FS Sheetpile Distance:	0 ft	B/Pile Cap:	-3.5 ft
Pile Cap Width:	26 ft	PS Sheetpile Distance:	0 ft	T/Wall Stem:	6 ft

Head EL Tail EL

10 yr.	9.000	0 ft
100 yr.	9.0000	0 ft
750 yr	9	0 ft
MaxD	9.0000	0 ft

Hydrostatic Pressure Values

AEP	P_{head} (T/CAP) [ksf]	P_{head} (B/CAP) [ksf]	P_{tail} [ksf]
10 yr	0.576	0.8	0.224
100 yr	0.576	0.8	0.224
750 yr	0.576	0.8	0.224
MaxD	0.576	0.8	0.224

Tailwater EL are currently assumed to be at normal water level (slightly conservative). More information requested from H&H will be added later on to determine more accurate tailwater pressures during flood events

750 yr. SWL capped at the TOW for a pre-overtopping event, since a higher SWL will create an overtopping event that will eventually equalize the hydrostatic pressure on both sides of the wall

Lateral Hydrostatic Pressure

Load	Fx [kip]	Fy [kip]	Fz [kip]	x [ft]	y [ft]	z [ft]	Mx [kip-ft]	My [kip-ft]	Mz [kip-ft]

Hsl_{750_H}	0.00			0.00				0	
Hsl_{MAXD}	0.00			0.00				0	

Surcharge Loads, ES

Since load combinations with surcharge as the principal lateral load are much smaller than lateral loads due to infrequent surge, surcharge loads will not be evaluated.

Live Loads, L

Live Loads due to traffic, rails, or equipment may be considered for other structures, but not for this floodwall structure

DYNAMIC LOADS, LD

Wind Loading, W

Select Risk Category:	IV		*Critical Structure*	
V =	170 mph		*Basic Wind Speed*	
Wind Directionality Factor, K_d =	0.85		*Table 26.6-1, ASCE-7 16*	
Select Exposure Category:	D			
Topographic Factor, K_{zt} =	1.0		*26.8.2, ASCE-7 16*	
Exposure Coefficient, K_z =	1.08	20 ft	*(use Table 26.10-1, ASCE 7-16)*	
Ground Elevation Factor, K_e	1			
$q_h = 0.00256K_zK_{zt}K_dK_eV^2$ (lb/ft^2)	q_h =	67.92 psf	*Eq. 26.10-1, ASCE 7-16*	
	Gust Factor, G =	0.85	*26.11.4, ASCE 7-16*	
	Clearance Ratio, R_{cl}=	1	*For Freestanding Wall*	
	Aspect Ratio, l/h =	0.000		
	C_f =	1.45	*Figure 29.3-1 ASCE-7 16*	
W = F = q_hGC_f (psf)	W =	**83.71 psf**	*Eq. 29.3-1 ASCE 7-16*	

750 year wind load is not included since the SWL will be above the top of wall during this event. Wind cannot act on the floodwall structure

Load	Fx [kip]	Fy [kip]	Fz [kip]	x [ft]	y [ft]	z [ft]	Mx [kip-ft]	My [kip-ft]	Mz [kip-ft]
10 yr Wind			0.00	-1.50				0	
100 yr Wind			0.00	-1.50				0

Design Summary:

The following calculations detail all load case for preliminary design for the L wall at +6ft Geometric parameters, elevations, and calculations of preliminary values, such as pile spacing can be found in the summary sheet.

Design Assumptions:

1. In this current iteration of the design, settlement loads are still preliminary and subject to change pending review

2. Additionally, the foundation dont include any uplift due to checks being preliminary

Vertical Earth Pressure, EV

Since there is no soil on top the floodwall structure, the vertical pressure due to soil is 0

Lateral Earth Pressure, EH

$\phi = \phi' =$	28	
$\theta =$	90	
$\delta =$	0	
$K_O =$	0.5305	
$K_P =$	2.7698	
(Amended) $K_P =$	1.119648879	
$K_A =$	0.3610	
saturated unit weight soil, Y_{sat}:	#REF!	pcf
submerged unit weight soil, Y':	#REF!	pcf
top of soil EL. =	2.00	ft
bot. of base EL. =	-3.50	ft
h =	5.50	ft
length of wall:	13	ft

Submerged earth pressures will be used on the floodside during flood events.

Saturated earth pressures will be used on the landside

Per EM 2502 Section II 3-4b, the passive pressure is adjusted to be 1/2 the calculate passive pressure due to the settlement being relatively small compared to what is needed to develop full passive resistance

Surface Soils have been revised to be sand per Geotechnical Engineers. This will be included/revised Post-35%

$$K_P = \frac{1 + \sin\phi}{1 - \sin\phi} = \tan^2\left(45° + \frac{\phi}{2}\right) = \frac{1}{K_A}$$

Passive/Active Pressure
EM 1110-2-2502 [3-20]

$$P_{PH} = \frac{1}{2} K_p \gamma' h^2 + 2c\sqrt{K_p}\, h$$

Passive Pressure
EM 1110-2-2502 [3-21]

$$P_A = \frac{1}{2} \gamma' \frac{1}{\sin\theta \cos\delta} K_A h^2$$

Active Pressure
EM 1110-2-2502 [3-11]

Downdrag, DD

Downdrag loads are are calculated by analyzing the negative skin friction and Settlement Induced Bending (SIB) (for battered piles) caused by the settlement of soil on deep pile foundations. This negative skin friction will only be applicable in the calculation of pile stresses and not pile capacity, however, SIB will be applied to all load cases. The value of these loads will be provided by the Geotechnical Engineer

TEMPORARY LOADS, LT

Hydrostatic Loads, Hs

Weight of Water, γ_w:	64 pcf	Heel Length of Wall:	0 ft	T/Pile Cap:	0 ft
Pile Cap Length:	26 ft	FS Sheetpile Distance:	0 ft	B/Pile Cap:	-3.5 ft
Pile Cap Width:	26 ft	PS Sheetpile Distance:	0 ft	T/Wall Stem:	6 ft

	Head EL	Tail EL	
10 yr.	9.000		0 ft
100 yr.	9.0000		0 ft
750 yr	9		0 ft
MaxD	9.0000		0 ft

Hydrostatic Pressure Values

AEP	P_{head} (T/CAP) [ksf]	P_{head} (B/CAP) [ksf]	P_{tail} [ksf]
10 yr	0.576	0.8	0.224
100 yr	0.576	0.8	0.224
750 yr	0.576	0.8	0.224
MaxD	0.576	0.8	0.224

Tailwater EL are currently assumed to be at normal water level (slightly conservative). More information requested from H&H will be added later on to determine more accurate tailwater pressures during flood events

750 yr. SWL capped at the TOW for a pre-overtopping event, since a higher SWL will create an overtopping event that will eventually equalize the hydrostatic pressure on both sides of the wall

Lateral Hydrostatic Pressure

Surcharge Loads, ES

Since load combinations with surcharge as the principal lateral load are much smaller than lateral loads due to infrequent surge, surcharge loads will not be evaluated.

Live Loads, L

Live Loads due to traffic, rails, or equipment may be considered for other structures, but not for this floodwall structure

DYNAMIC LOADS, LD

Wind Loading, W

Select Risk Category:	IV		*Critical Structure*	
V =	170 mph		*Basic Wind Speed*	
Wind Directionality Factor, K_d =	0.85		*Table 26.6-1, ASCE-7 16*

US Army Corps of Engineers

General Reevaluation Report with Integrated Supplemental Environmental Impact Statement

Appendix H — Climate Change Analysis

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

This document contains CONTROLLED UNCLASSIFED INFORMATION (CUI). It contains information that may be exempt from public release under the Freedom of Information Act (5 USC 552). It is to be controlled, stored, handled, transmitted, distributed, and disposed of in accordance with USACE policy relating to CUI information and it is not to be released to the public or other personnel who do not have a valid “need to know” without prior written approval of an authorized USACE official.

Report Status: Draft, November 2023

Executive Summary

This is an ECB 2018-14 evaluation of potential climate vulnerabilities facing the Ala Wai Canal, conducted to complement the Flood Risk Management General Reevaluation Study. The Ala Wai Canal is a 2-mile-long, man-made waterway constructed during the 1920s to drain extensive coastal wetlands, thus allowing development of the Waikiki district. It receives inflows from the Makiki, Manoa, and Palolo streams.

This assessment was performed to highlight existing and future challenges facing the project due to past and future climatic changes, in accordance with the guidance in Engineering Construction Bulletin (ECB) 2018-14, revised 10 Sep 2020. Background information on the project can be found in the 2021 feasibility study and in the main body of the 2022 General Reevaluation Report (GRR) (this climate assessment is intended as an appendix to the GRR); background information on climate-affected risks to projects and assessments thereof can be found in the ECB.

CEPOH is reviewing the stream/floodwall/canal system for flood control purposes. For this study, tourism, recreation and environmental purposes, are regarded as secondary to inundation due to riverine flooding and tidal effects. Consequently, riverine flood operations and tidal effects are the focus of this climate analysis.

The intent of the project is a reduction in flooding due to precipitation and associated streamflow. Although this is linked to sea level rise via the downstream boundary of the watershed, the coastal inundation and storm flooding due to SLC are not being addressed by these proposed measures. The project is not intended to reduce coastal storm damage and/or sunny day flooding due to relative sea level change.

The following list summarizes the climate assessment conclusions for the Ala Wai basin area.

1. Inundation of the Ala Wai Canal area would potentially affect a permanent population of 65,000 people with a daily transient population (mostly tourists) of 200,000.
2. Annual flood damages have been assessed for the current layout (Future Without Project condition) as $32.2 million (FY2021 dollars were assumed).
3. More than 40 combinations of floodwalls, flapgates, levees, tunnels and pumpstations were reviewed; the team's tentatively selected project (TSP) has been selected based on expected conditions through 2080, with acknowledgement that in the event of even higher water levels (more from relative sea level rise than from riverine flow changes) the design should be adaptable to the changes (wider levees and floodwalls at which vertical additions would be feasible).
4. Mean temperatures in Hawaii are projected to rise by 2 to 4 °F by the end of the 21st century (NOAA gives a range of 2 °F to 10 °F for Hawaii).
5. There is agreement in the literature that average rainfall is likely to decrease on Oahu.
6. There is less certainty over whether intense rainfall events are expected to increase or decrease in frequency, although the NCA4 does indicate that the frequency is increasing.
7. The effects of any seasonal rainfall trends are masked by observed and projected cyclical El Niño/La Niña changes, which seem to be occurring more frequently than the historical 7-year cycles.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

8. The Hawaiian Islands are small, relative to the typical modeling cell size in typical climate models, and so the models' projections for Hawaii are in general less clear than for the continental United States.
9. The literature review did not lead to a clear projection that inundation floods should be expected to occur more, or less, frequently. Both intense precipitation events and dry periods were expected to be more frequent, while the overall annual flow is expected to remain about the same.
10. A review of site-specific streamflow for the years 1968 to 2021 revealed no monotonic trends, and no nonstationarities.
11. The USACE Time Series Tool was used to prepare projections from the available data. The tool projected forward to the year 2034 using two different sets of assumptions (Autoregressive Integrated Moving Average (ARIMA) or exponential) but both extrapolation techniques allowed for "no change" to the expected annual peak flows (no trend), with large uncertainty bands.
12. The project is intended to decrease flood risk losses (lives or flood damages). The USACE Climate Hydrology Assessment Tool (CHAT) does not cover the Hawaii Region in its Vulnerability Assessment, and so a scoring of how the location is more vulnerable, or less so, with respect to flooding, than projects in other districts, has not been prepared. That the project was authorized indicates a concern that the vulnerability is significant relative to locations in the contiguous United States (CONUS).

Listing of Acronyms for Climate Change Executive Summary

Acronym	Meaning
°C	Degree Celsius (or degree Centigrade)
°F	Degree Fahrenheit

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Acronym	Meaning
A1, A2	GCM settings A1 and A2 assume levels of increases in greenhouse gas emissions.
AEP	Annual Exceedance Probability
ARIMA	Autoregressive Integrated Moving Average
B1, B2	GCM settings B1 and B2 assume levels of reductions in greenhouse gas emissions.
BC	Boundary Condition. Of importance in the Ala Wai Canal watershed study was the assumed final water level BC, taking into account combinations of storm surge, sea-level change, and Inter-Annual Variability.
BCSD	Bias Corrected Spatially Disaggregated
CHAT	Climate Hydrology Assessment Tool
CMIP	Coupled Model Intercomparison Project
CONUS	Contiguous/Conterminous/Continental United States
CoP	Community of Practice
ECB	Engineering Construction Bulletin
ENSO	El Niño Southern Oscillation
EWL	Extreme Water Level
FWOP	Future Without Project (scenario used in assessing possible changes)
FY	Fiscal Year
GCM	Global Climate Model (or General Circulation Model)
GHM	Global Hydrologic Model
GMT	Greenwich Mean Time (or Greenwich Meridian Time). Noon in Hawaii corresponds to 2200 hrs GMT.
GRR	General Reevaluation Report
H&H	Hydrology and Hydraulics
HEC-RAS	Hydrologic Engineering Center – River Analysis System

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Acronym	Meaning
HUC	Hydrological Unit Class (or classification)
IAV	Inter-Annual Variability (water surface fluctuations in the ocean, caused by irregular fluctuations in coastal ocean temperatures, salinities, winds, atmospheric pressures, and ocean currents). NOAA 2022 indicates that ENSO is a large factor in IAV in Pacific Ocean stations.
MHHW	Mean Higher High Water
mm	Millimeter(s)
NAVD/ NAVD88	North American Vertical Datum of 1988
NCIA	Northeast Climate Impact Assessment
NCA, NCA4	(Fourth) National Climate Assessment
NGVD/ NGVD29	National Geodetic Vertical Datum of 1929
NOAA	National Oceanic and Atmospheric Administration
NSD	Non-Stationarity Detection
PAR	Population at Risk
POH, CEPOH	USACE Pacific Ocean Honolulu District
Q_n	Peak flow expected with a return period on average of n years (AEP is 1/n)
R^2	Coefficient of Determination (square of R the correlation coefficient)
R25	Total number of days per annum with precipitation above 1 inch (corresponds to 25 mm)
R5d	Annual maximum 5-day precipitation amount
R95p	Fraction of annual total precipitation from events exceeding the 1961-1990 95th percentile
RCM	Regional Climate Model
RCP	Representative Concentration Pathway. Scenario for future greenhouse gas emissions total. RCP 4.5 is considered low; RCP8.5 is considered high.
SDII	Simple Daily Intensity Index (regarding rainfall)

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Acronym	Meaning
SLC, RSLC	Sea-Level Change, Relative Sea-Level Change
SQRA	Semi-Quantitative Risk Assessment
TST	Time Series Tool
USACE	US Army Corps of Engineers
USBR	US Bureau of Reclamation
USGS	US Geological Survey
VA	Vulnerability Assessment
VIC	Variable Infiltration Capacity
WOWA	Weighted-Order, Weighted-Average

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

1. Literature Review

The Ala Wai Canal is situated in the Waikiki District, near Honolulu in Oahu Island, Hawaii. Hawaii constitutes the US Geological Survey's Water Resources Region number 20 (Seaber et al 1987). Given the canal's flood risk management purpose, climate variables of greater concern include any increases in precipitation or increased streamflow to the canal. Examples are extreme precipitation events such as occurred in November 1965, December 1967, during Hurricane Iniki in 1992, or in storms in October 2004, March 2006, October-November 2006, December 2008, June 2011, April 2018, and December 2021 (NOAA, 2022).

Additional flooding occurred in March 2006 as part of an extended rain event caused by a developing La Niña pattern (NOAA National Weather Service, 2006). La Niña cycles tend to amplify and extend the winter wet season, creating above normal rainfall and frequency of thunderstorms (Bravender, 2011). Hurricanes have not historically posed a significant threat of headwater flooding from long duration, intense precipitation. Due to the location of the Hawaiian Islands in the Pacific relative to a high-pressure feature to the northeast, large storms are usually deflected or weakened before they approach the region. Cooler waters also play a role in weakening tropical systems that track through the area (Puleo, 2020).

Kona lows are more typical storm events affecting the watershed and the Hawaiian Islands generally. The word "kona" is Hawaiian for "leeward" which means the side of an island that is usually sheltered from prevailing trade winds and associated rainfall; the trade winds typically come from the northeast to east-northeast. Kona lows are subtropical storms that occur during the cool season in the north central Pacific. Historically, kona lows bring abundant moisture from the southwest which can produce significant precipitation in multiple forms (e.g., rain, snow, hail) in short time periods, leading to flash flooding and other related storm damages (Mossison & Businger; NOAA NESDIS, 2021).

Hawaii is also subject to astronomical tidal events. There are two high tides per day, in a cycle that follows the daily (repeating approximately every 24 hours 50 minutes) moonrise and moonset events, with timing delays that can be precisely calculated for a given location, Honolulu's shoreline in this case, on the earth. The gravitational attraction effect from the moon is greatest at the midpoint in time between moonrise and moonset, and again at the midpoint between moonset and the following moonrise, but the oceans' response depends on how the water is affected by the obstacles of shallow or deep obstacles in the approach to islands and continents. The major driving factor in these cycles is the gravitational influence of the moon on the water in the oceans of the rotating earth. The effect of the high tide when the moon is not visible (after moonset, before moonrise) is an anomaly of the "forcing" effect of the moon on the harmonic tidal nature of the ocean's cyclic motion.

The size of the high and low tides varies, depending also on the smaller gravitational influence from the sun. At new moon and full moon, the tides are particularly large owing to the interplay of the moon and sun on the motion of the oceans. At these times, the earth, moon and sun are aligned most nearly in a straight line (the straight-line alignment is exact during full eclipses).

Separately, it is noted that the effect of the moon on the tides is greater once per lunar month when the moon is at perigee (closest in its elliptical orbit to the earth), and smaller at apogee

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

(moon farthest from the earth). Tidal effects and relative sea-level change are reviewed in more detail in the "Sea Level Change" subsection of the Literature Review section.

Table 0.1 is a summary of relevant climate data for a 30-year period 1991-2020 at the Daniel K. Inouye International Airport, 7 miles west of the Ala Wai Canal location.

A January 2015 literature synthesis conducted by the USACE Institute for Water Resources (USACE 2015) summarizes the available climate change literature for the Hawaii region, covering both observed and projected changes. These include temperature, precipitation, and streamflow. Wuebbles, D.J. et al 2017 (Volume 1) and Reidmiller, D.R. et al 2018 (Volume 2) reviewed climate changes in progress in the United States in a report widely referred to as simply the fourth National Climate Assessment (NCA) or NCA4. Keener et al (2018) prepared Chapter 27 of Volume 2 of NCA4. Chapter 27 has as its focus Hawaii and the U.S.-Affiliated Pacific Islands. The USACE literature synthesis and NCA4 are the two major sources of the information referenced in this literature review. The focus of these references is on summarizing trends identified within historical and observed temperature, precipitation, and streamflow records, as well as providing an indication of future hydrometeorology based on the outputs from Global and Regional Climate/Circulation Models (GCMs and RCMs). In this assessment, background on observed and projected temperature and precipitation is provided as context for the impact they have on observed and projected streamflow.

2. Temperature

2.1 Temperature Observations

Observed changes in annual average temperature for the Hawaii Region have increased by 1.26 °F for the 1986-2016 period relative to the 1925-1960 period. Observed annual average maximum and annual average minimum temperature have increased by 1.01 °F and 1.49 °F in the Hawaii region, respectively (Keener et al (2018)). The NCA4 noted temperatures having risen 0.76 °F in Hawaii from 1918 to 2018, with 2015 and 2016 having been the two warmest years on record through 2018 (Keener et al, 2018 [NCA4 Vol2, Ch 27]). The average annual temperatures since 1918 are summarized in Figure 0.1.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

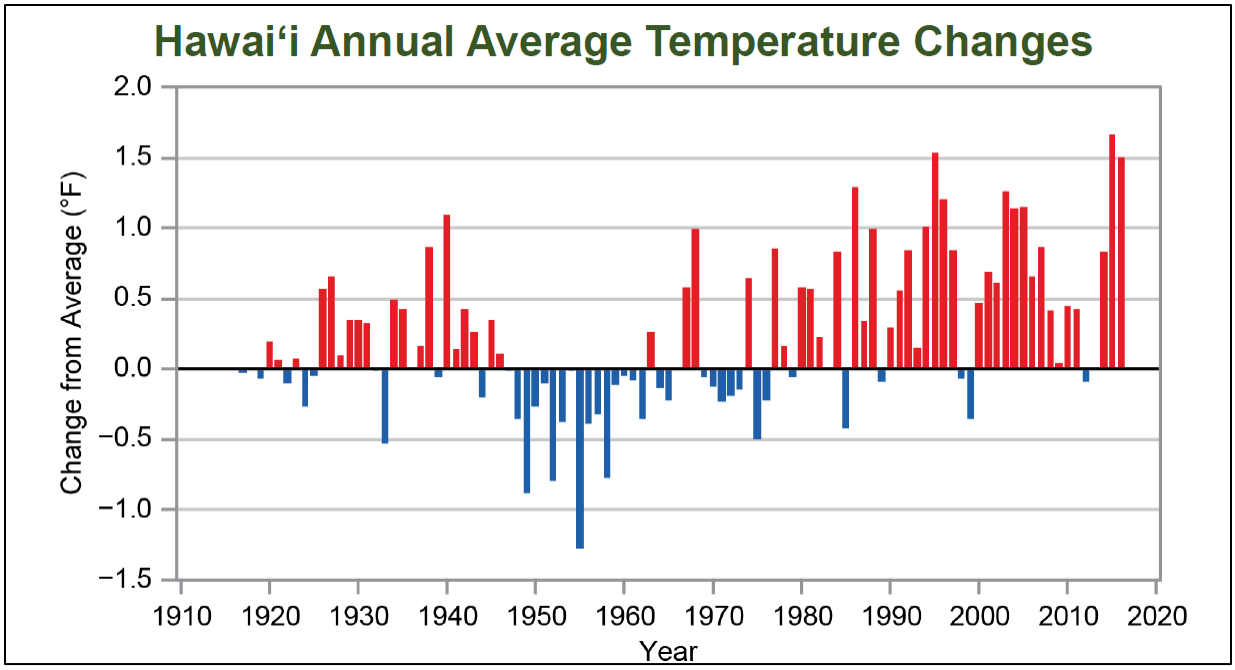

Figure 0.1 Rising temperatures since 1918 compared to 1944-1980 average (from University of Hawaii at Manoa, reported in NCA4 Vol 2 Ch 27).

Safeeq et al (2013) reviewed temperatures at 7 stations on Oahu over the years 1969 to 2007. Although mean and maximum temperatures appeared to be increasing, the trends were not significant. The annual minimum temperature, however, had increased significantly at six stations on the leeward side of the island, while there was one station on the windward northern side of the island where the annual minimum temperature was decreasing significantly. At the Ala Wai Canal, the annual minimum temperature appeared to have been increasing by approximately 0.05 °C per year (5 °C or 9 °F per century). This is shown in Figure 0.2. The Safeeq et al (2013) team noted that night-time minimum temperatures were rising in general, resulting in a smaller diurnal temperature range (DTR) over time. The decrease between daily maximum and minimum values had also been noted by Fletcher (2010) in a review of climate change briefing paper by the University of Hawaii at Manoa.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

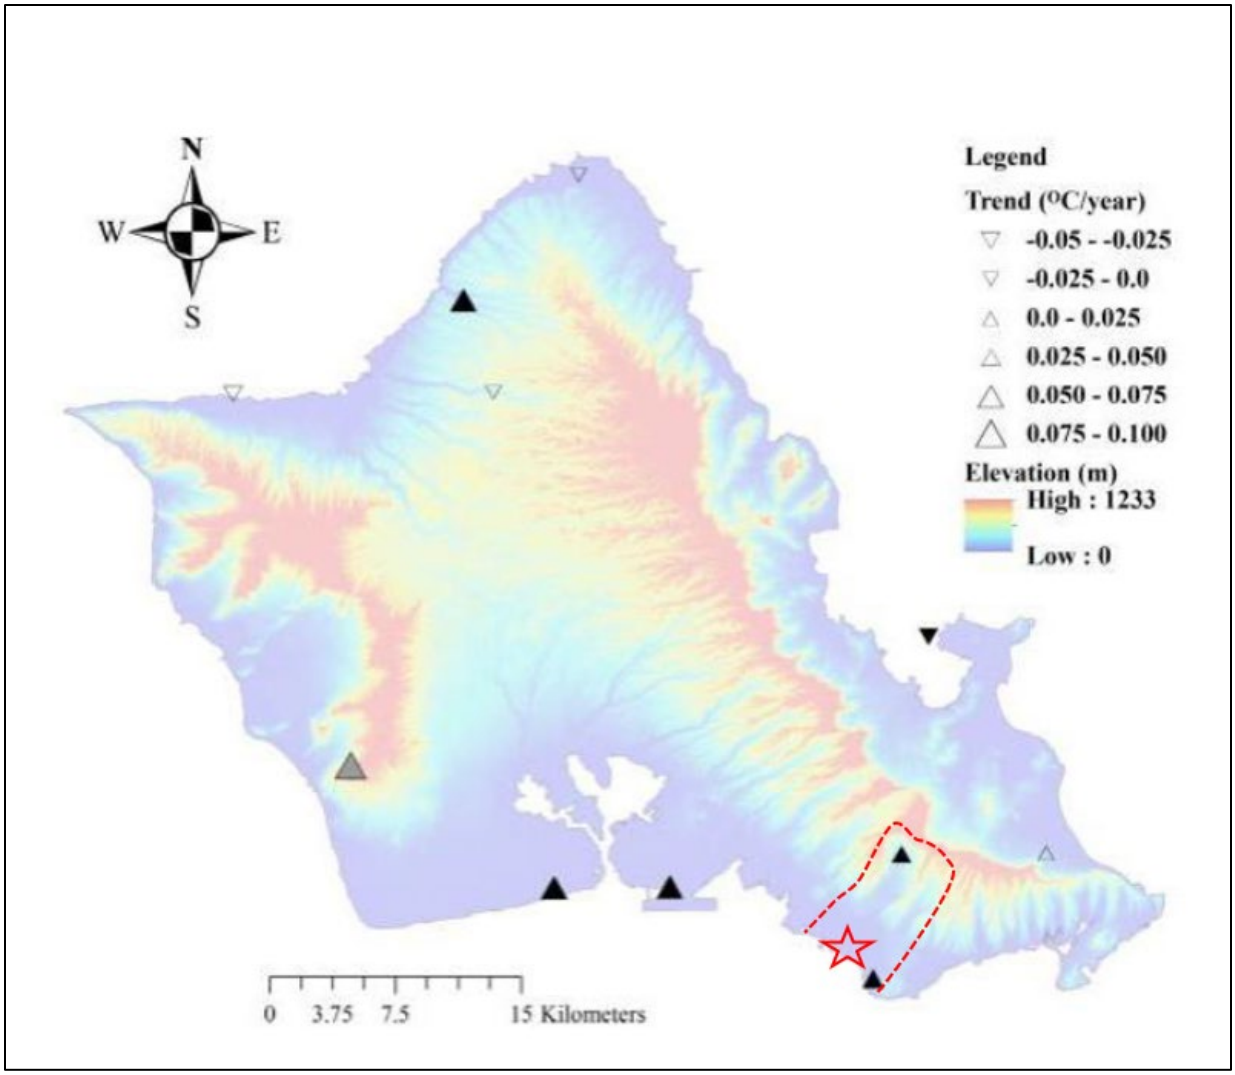

Figure 0.2 Safeeq et al 2013 Review of Annual Minimum Temperature Changes in the Oahu Region. The approximate location of the Ala Wai Canal is noted with a star; the approximate limits of the Ala Wai watershed are noted with a broken red outline.

2.2 Temperature Projections

NCA4 (Keener, V. et al (2018)) reviewed temperature changes and projected RCP 4.5 and RCP 8.5 models. The temperature projections are summarized in Figure 0.3. The cyclical climatic effects El Niño and La Niña were expected to increase in frequency, and they would also add to uncertainty over how temperatures would change in Hawaii. In review of temperature changes under RCPs ranging from RCP4.5 to RCP8.5, NCA4 V1 Ch6, (Vose et al, 2018) noted expected temperature increases of 4.0 to 6.0 °F (2.2 to 3.3 °C) by 2099, expected to be the smallest temperature increases in the United States, owing to the tempering effects of the surrounding Pacific Ocean. They tabled minimum, mean, and maximum temperatures in Hawaii as rising over time by 1.49, 1.26, and 1.01 °F as derived from the nClimDiv dataset.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

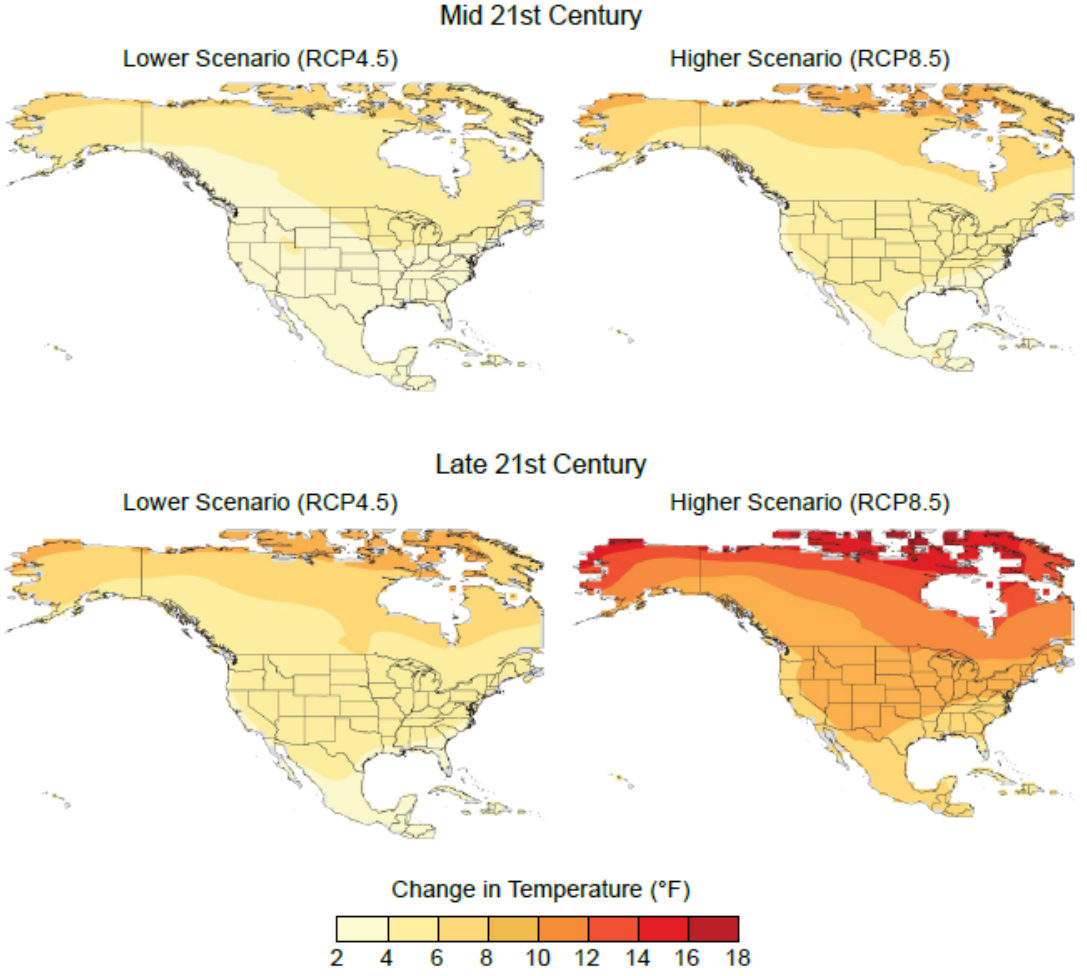

Figure 6.7. Projected changes in annual average temperatures (°F). Changes are the difference between the average for mid-century (2036–2065; top) or late-century (2070–2099, bottom) and the average for near-present (1976–2005). Each map depicts the weighted multimodel mean. Increases are statistically significant in all areas (that is, more than 50% of the models show a statistically significant change, and more than 67% agree on the sign of the change[45]). (Figure source: CICS-NC and NOAA NCEI).

Figure 0.3 Projected Temperature-Changes Reported in NCA4 – for Hawaii, increases by 2099 of 4.0 to 6.0 °F (2.2 to 3.3 °C) were projected.

Leong et al (2014) in NCA3 examined results of projected increases in average temperature ranges of 1.5 °F (0.83 °C) by 2055 relative to 1971-2000) under a scenario of substantial emissions reduction (B1) to 3.5 F (1.9 °C) assuming continued increases in emissions (A2). Walsh et al (2014) developed an increase in temperatures ranging from 3 °F to 5 °F (1.7 °C to 2.8 °C), for the scenarios shown in Figure 0.4.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

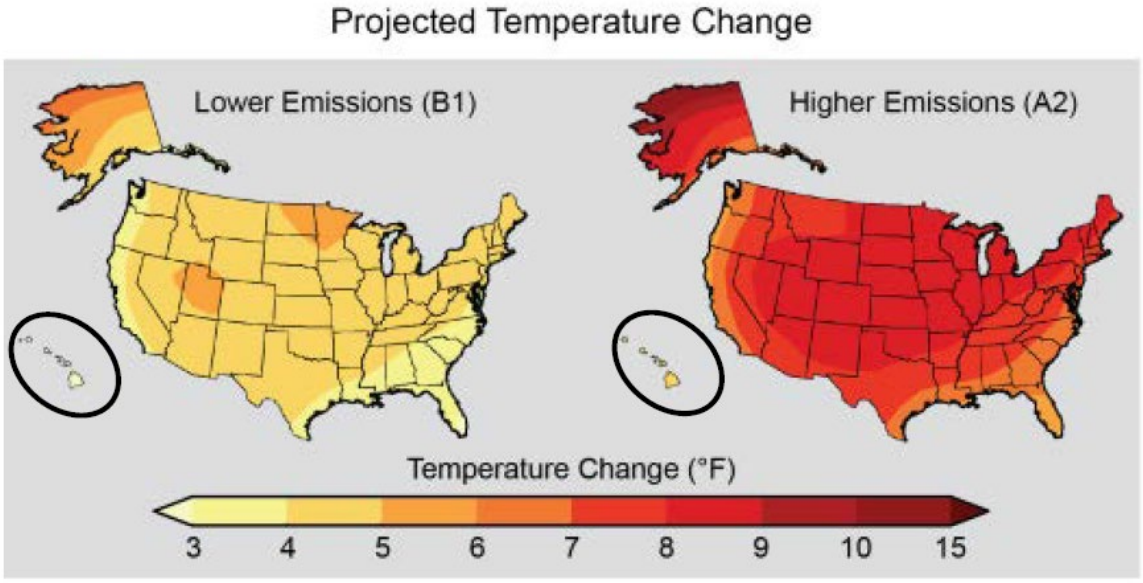

Figure 3.1. Projected changes in average surface air temperature (°F) between 2071-2099 relative to the 1970-1999 for B2 (low emissions) scenario (left) and A2 (high emissions) scenario (right). The Hawaii Region is within the black oval (Carter et al., 2014).

Figure 0.4 Projected Air Temperature Changes. Based on NCA3 (Walsh et al) as reported by CDM Smith in USACE (2015). For Hawaii, the ranges are 3 °F to 5 °F (1.7 to 2.8 °C)

Keener et al (2013) reviewed the results of climate models assuming high (A2) or low (B1) emissions scenarios to develop similar estimates for Hawaii: mean annual temperatures were projected to rise by 2 °F (1.1 °C) under B1 scenario, or by 5 °F (2.8 °C) through the end of the 21st century. The result is presented in Figure 0.5.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

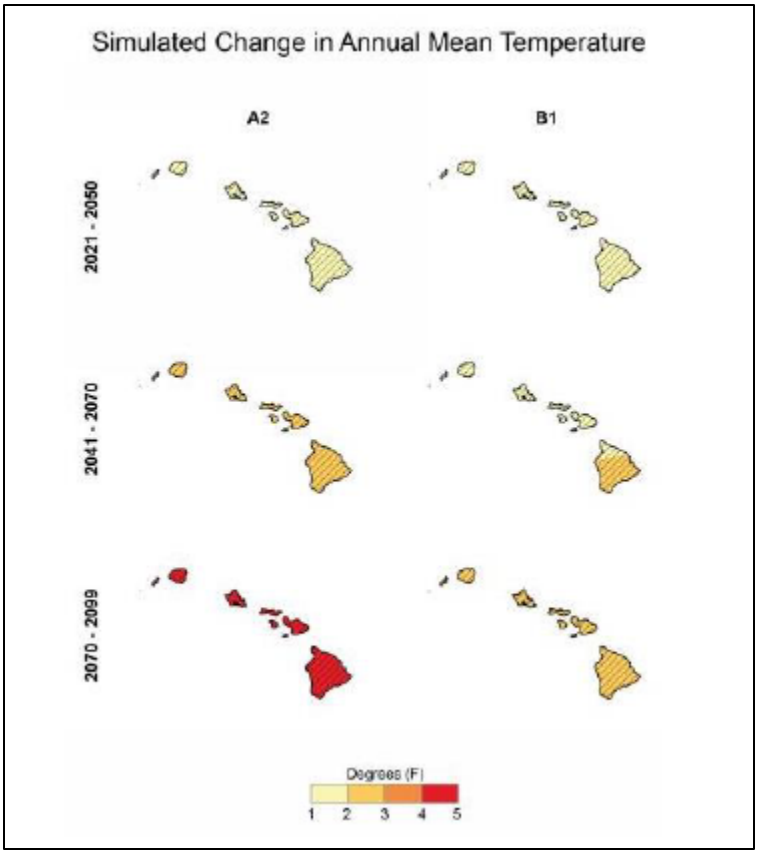

Figure 0.5 Projected changes in annual mean temperature in Hawaii (°F) between 2021-2099 for the A2 (high emissions) scenario (left) and B1 (low emissions) scenario (right) (Keener et al, 2013).

NOAA has published a set of individual state climate summaries containing information on historical climate variations and trends, future climate model projections of climate conditions, and past and future conditions of sea level and coastal flooding. Regarding temperatures in Hawaii, NOAA reported (Stevens et al 2022) that temperatures had risen by about 2 °F since 1950, with a sharp increase in warming over the most recent decade (2010 to 2020). For Honolulu, NOAA report noted that temperatures had increased by 2.6 °F and had been consistently above the 1951-1980 average since 1975. The annual number of days below freezing was reported to be decreasing over time, and the daily temperature range was decreasing over time, largely due to nighttime warming.

Figure 0.6 provides a summary of the expected changes, based on the two scenarios (RCP4.5 and RCP8.5) in which greenhouse emissions either continue to increase (higher emissions) or increase at a slower rate. Although the figure is taken from the state-specific NOAA report (Stevens et al 2022), the NOAA report refers to work by Vose et al at North Carolina State University in 2014. Observed temperatures are generally within the envelope of model simulations of the historical period (gray shading). Historically unprecedented warming is projected during this century. Less warming is expected under a lower emissions future (the coldest end-of-century projections being about 2 °F warmer than the historical average; green shading) and more warming under a higher emissions future (the hottest end-of-century projections being about 10 °F warmer than the hottest year in the historical record; red shading).

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

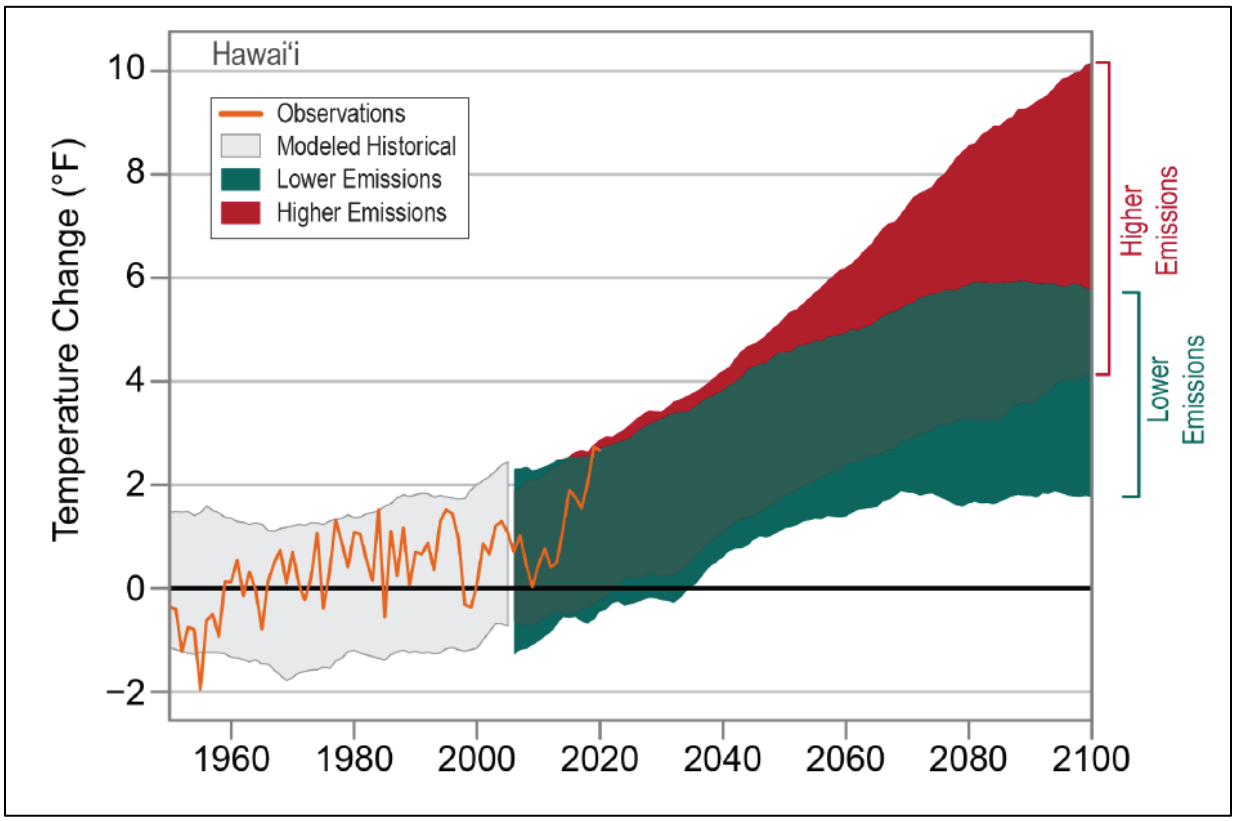

Figure 0.6 Observed and Projected Temperature Change in Hawaii (Source: NOAA State Climate Summary 149-HI)

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

3. Precipitation

3.1 Precipitation Observations

NCA4 Volume 2 Chapter 27 noted regions of the Hawaiian Islands in which the change in flow levels was statistically significant. For Oahu, the percentage change in precipitation per decade was mostly small (a decrease of less than 4% per decade), although there was a region of larger and statistically significant change on the windward (unsheltered) northern mountains, draining to the north (away from the Ala Wai Canal area). These trends are shown in Figure 0.7.

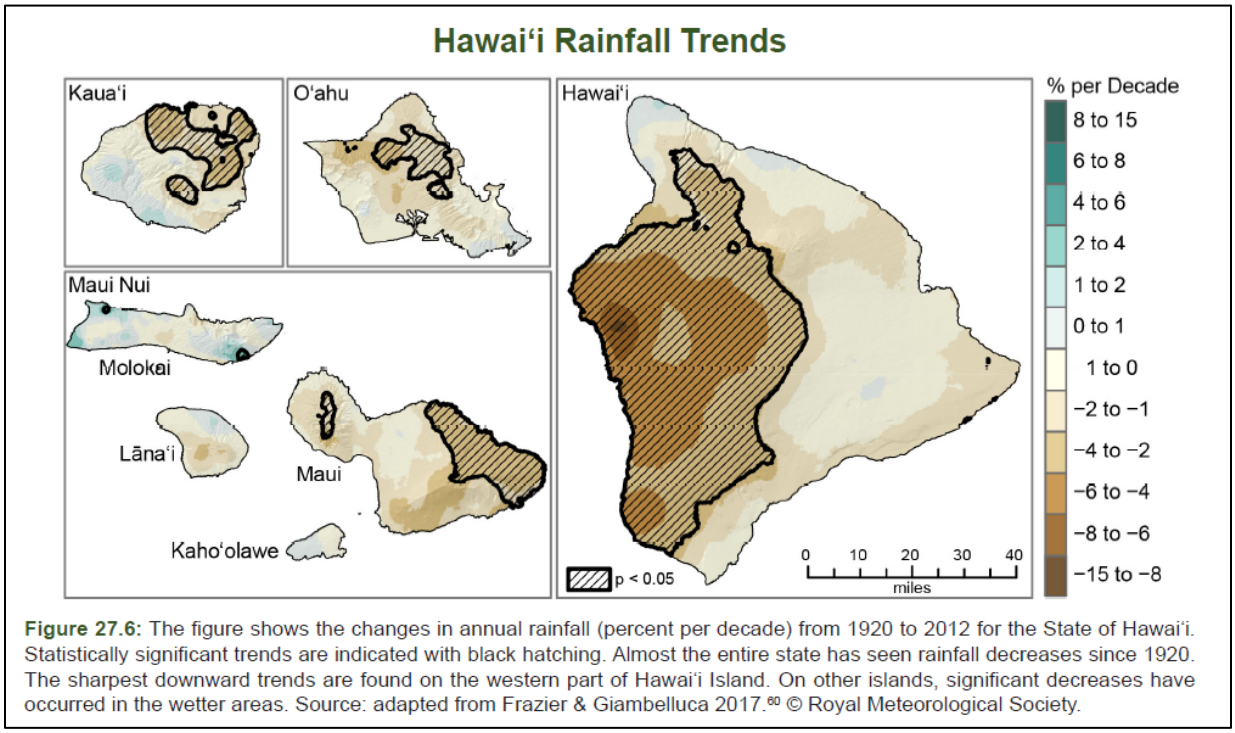

Figure 27.6: The figure shows the changes in annual rainfall (percent per decade) from 1920 to 2012 for the State of Hawai'i. Statistically significant trends are indicated with black hatching. Almost the entire state has seen rainfall decreases since 1920. The sharpest downward trends are found on the western part of Hawai'i Island. On other islands, significant decreases have occurred in the wetter areas. Source: adapted from Frazier & Giambelluca 2017.[60] © Royal Meteorological Society.

Figure 0.7 Observed Rainfall Trends in Hawaii 1920-2012 (Source: NCA4)

Fletcher (2010) noted, however, that despite the decreases in average precipitation (he cited a 15% reduction in rainfall over the previous 20 years), there was a trend of increasing rain intensity. He reported a 12% increase in the heaviest downpours (measured as the heaviest 1% of all events) for the period 1958 to 2007.

Fletcher's findings were at odds with the studies by Chen and Chu (2014) and Chu et al (2010). These studies both found that the incidence of intense precipitation was decreasing on Oahu. Data reviewed by Chen and Chu (2014) included the frequency of 300-mm (12-inch) storms 1960 to 2009, while Chu et al (2010) reviewed, for the epochs 1959-1979 and 1980-2007: total number of days with precipitation above 1 inch (R25); the simple daily intensity index (SDII); annual maximum 5-day precipitation amount (R5d); and the fraction of annual total precipitation from events exceeding the 1961-1990 95th percentile (R95p). It should be noted that the island of Hawaii, south-east of Oahu, appeared to be experiencing more, not fewer, intense rainfall events.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

The USGS has prepared a useful summary figure showing rainfall in the Hawaiian Islands. This is presented as Figure 0.8. It is noted that the Ala Wai Canal area has an expected annual rainfall total of less than 40 inches, but that the contributing drainage basin region includes regions shaded to indicate precipitation of 40-80 and 80-120 inches, and a smaller regions of greater peak values listed as noted.

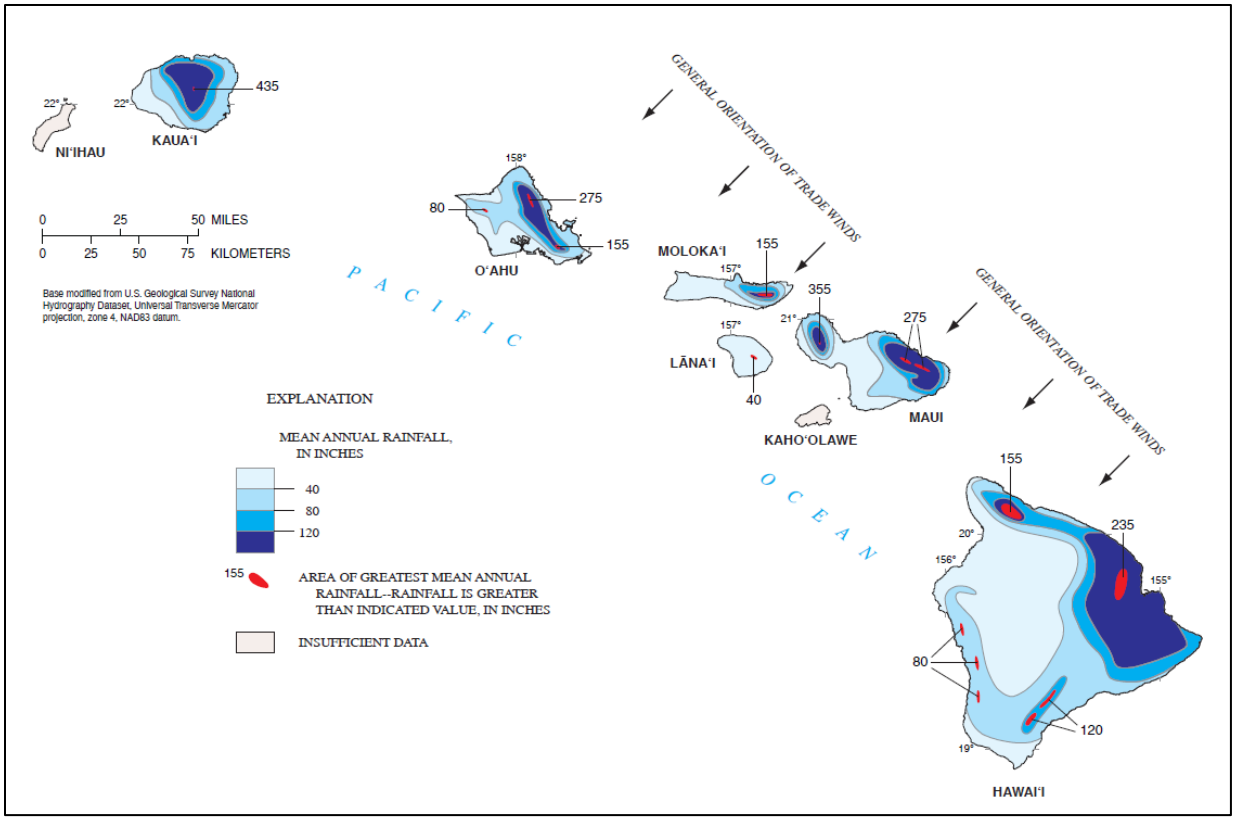

Figure 0.8 Rainfall Observed in the Hawaiian Islands (from Oki 2014, modified from Giambelluca et al, 1986).

Giambelluca (2013) prepared a meteorological report for Hawaii that included the map in Figure 0.9

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

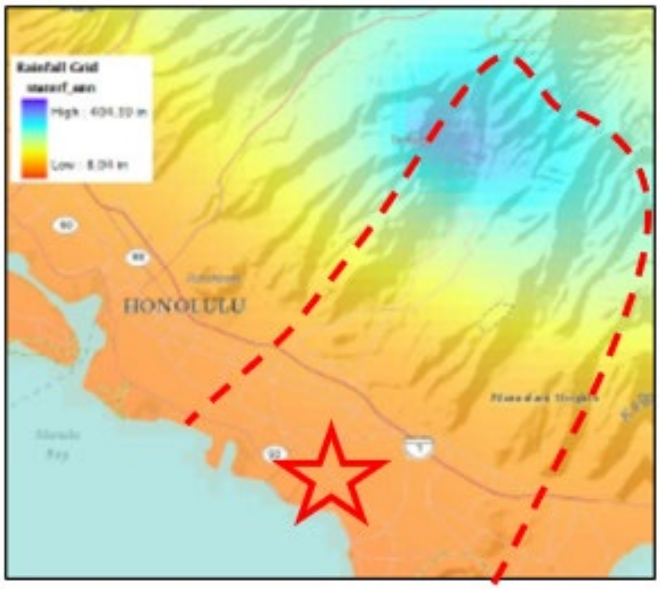

Figure 0.9 Mean Annual Rainfall View of the Waikiki Drainage Basin Area, from Giambelluca (2013). The approximate boundary of the watershed is shown with a red dotted line; the approximate location of the canal is shown with a red star.

USACE 2021 reviewed the USGS report. The USACE (2021) summary included that the 16.2 square-mile basin included Makiki and Manoa watersheds with annual rainfall of more than 160 inches per annum, with less rain falling on the Palolo section of the watershed. The less steep regions around Ala Wai and Waikiki, received about 30 inches per annum. USACE (2021) noted that these regions of lower overall rainfall were also more urbanized, more impervious, and better served by a storm drain system, contributing to flashy runoff behavior with a typical time to peak of less than 1 hour, and a typical total flood hydrograph duration less than 6 hours.

3.2 Precipitation Projections

Keener et al (2018) report projected changes in precipitation of small-to-30% increases in end-of-century precipitation under a higher-scenario (RCP 8.5) case, with small-to-60% decreases in precipitation for dry areas under the same RCP 8.5 case. The report noted uncertainty arising from downscaling as a matrix of large (190-mile x 190-mile) cells is used in the model, but less crude results are required for forecasting purposes at locations as individual watersheds in the individual islands in Hawaii. For the Ala Wai Canal project, for example, the project has a basin area smaller than 30 square miles. Different downscaling methods lead to different results. The authors note that for the lower scenario RCP4.5, decreases of up to 60% should be expected in the sheltered areas of Oahu (south side of the island) for the period 2071-2100, relative to the range observed 1920-2021, with similar expected changes for the more extreme RCP8.5 (decreases of 10% to 60%). The authors noted that the number of climate and water resources monitoring stations had declined in the region, reducing the ability of researchers to project future changes in climate.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

The NOAA report for the State noted trends of northern Hawaii receiving less annual precipitation over the current century, compared to the late 20th century, with the main island and southern islands receiving up to 5% more precipitation by the middle of the 21st Century, while more northern Hawaiian Islands would receive up to 5% less precipitation. This summary figure is shown in Figure 0.10.

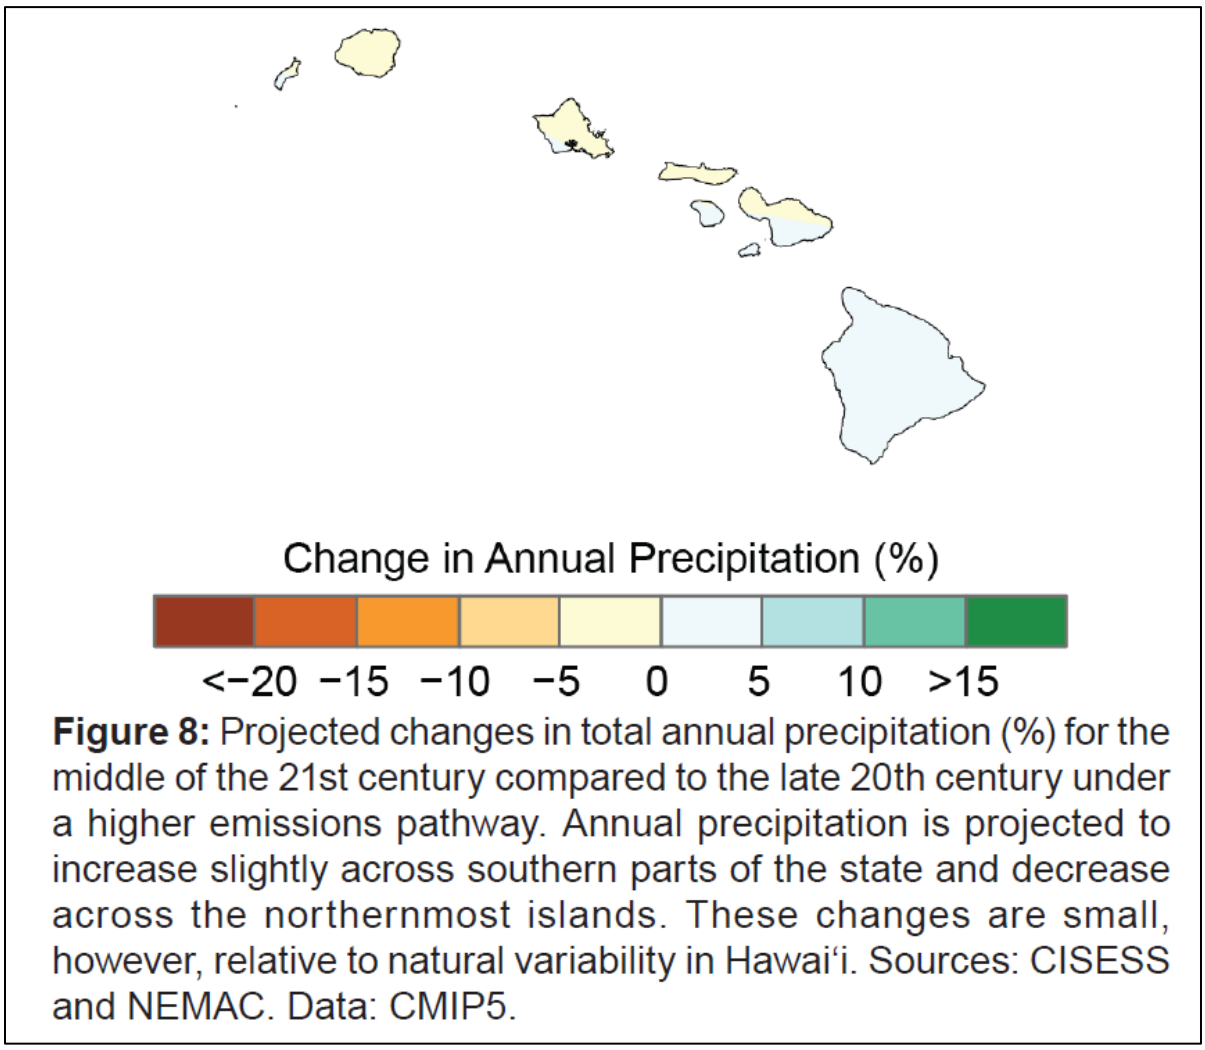

Figure 8: Projected changes in total annual precipitation (%) for the middle of the 21st century compared to the late 20th century under a higher emissions pathway. Annual precipitation is projected to increase slightly across southern parts of the state and decrease across the northernmost islands. These changes are small, however, relative to natural variability in Hawai'i. Sources: CISESS and NEMAC. Data: CMIP5.

Figure 0.10 Changes in total annual precipitation in Hawaii for the mid-21st century, compared to the late 20th century.

While Oahu fell mostly into the "less precipitation" category, the Waikiki region appeared to be on the edge of the "more" and the "less" precipitation zones. The NOAA report noted that the projected changes were small compared to the natural variability of precipitation in the State.

USACE (2015) reported a similar divergence of results in the NCA3 report (Walsh et al, 2014), based on different emissions projections and seasons: winter and spring (wet-season period is roughly October through April) precipitation was not expected to change in the 20th century, but

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

summer and fall (dry season) were potentially 10% to 30% wetter, although the increase was not found to be statistically significant.

The NCA4 (Keener et al, 2018) referenced primarily model results from RCP4.5 and RCP8.5 emissions assumptions. The NCA4 acknowledged previous findings of a decreasing trend in the number of extreme rainfall events in Hawai‘i, but indicated that both droughts and floods were becoming more frequent in the state. This finding was made, based on “a more detailed spatiotemporal analysis from a grid-box level down to the island level”.

Hotter, drier soil conditions are expected to increase the rate of soil moisture loss in the leeward side of the island, where lower annual rainfall is expected. Droughts are therefore likely to become more intense (Stevens et al, in NOAA 2022). The observed and projected changes in peak streamflow are reviewed in the section on Streamflow.

4. Cyclical Patterns: El Niño Southern Oscillation and La Niña

Every 3 to 7 years climate conditions over the Pacific Ocean basin change dramatically because of the El Niño-Southern Oscillation (ENSO). The extremes of this oscillation are referred to as El Niño and La Niña.

As summarized by NOAA’s Pacific ENSO Applications Climate Center, an El Niño event would typically result in the following climate impacts in Hawai‘i:

- More rain the beginning of the season, then rapidly less;
- Weaker trade winds, with occasional westerly winds;
- Near, to slightly above, normal sea level;
- High run-up from distant swells;
- Much warmer temperatures at and below the sea surface; and
- Increased risk of tropical cyclones (storms form closer and move towards the islands).

The strength of these ENSO-related patterns in the short term can make it difficult to detect the more gradual, long-term trends of climatic change. It is unknown how the timing and intensity of ENSO will continue to change in the coming decades, but recent climate model results suggest a doubling in frequency of both El Niño and La Niña extremes in the 21st century as compared to the 20th century under scenarios with more warming (Keener et al (2018)).

The NCA4 outlines changes that have been observed in the Pacific in the year that follows an El Niño event. While the Hawaiian Islands do not appear to be affected by the temporary increases or decreases in sea levels, they are in a region mapped as subject to especially dry weather in January through March (the middle to the end of the typical rainy season) following an El Niño event, with an increased frequency of tropical cyclones immediately south of the islands during the El Nino event, potentially affecting the south-facing Waikiki region with increased rains; and especially wet weather in December through February (also late in the typical rainy season) following a La Niña event. The effects of El Niño/ La Niña cycles on Pacific weather patterns are shown in Figure 0.11.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

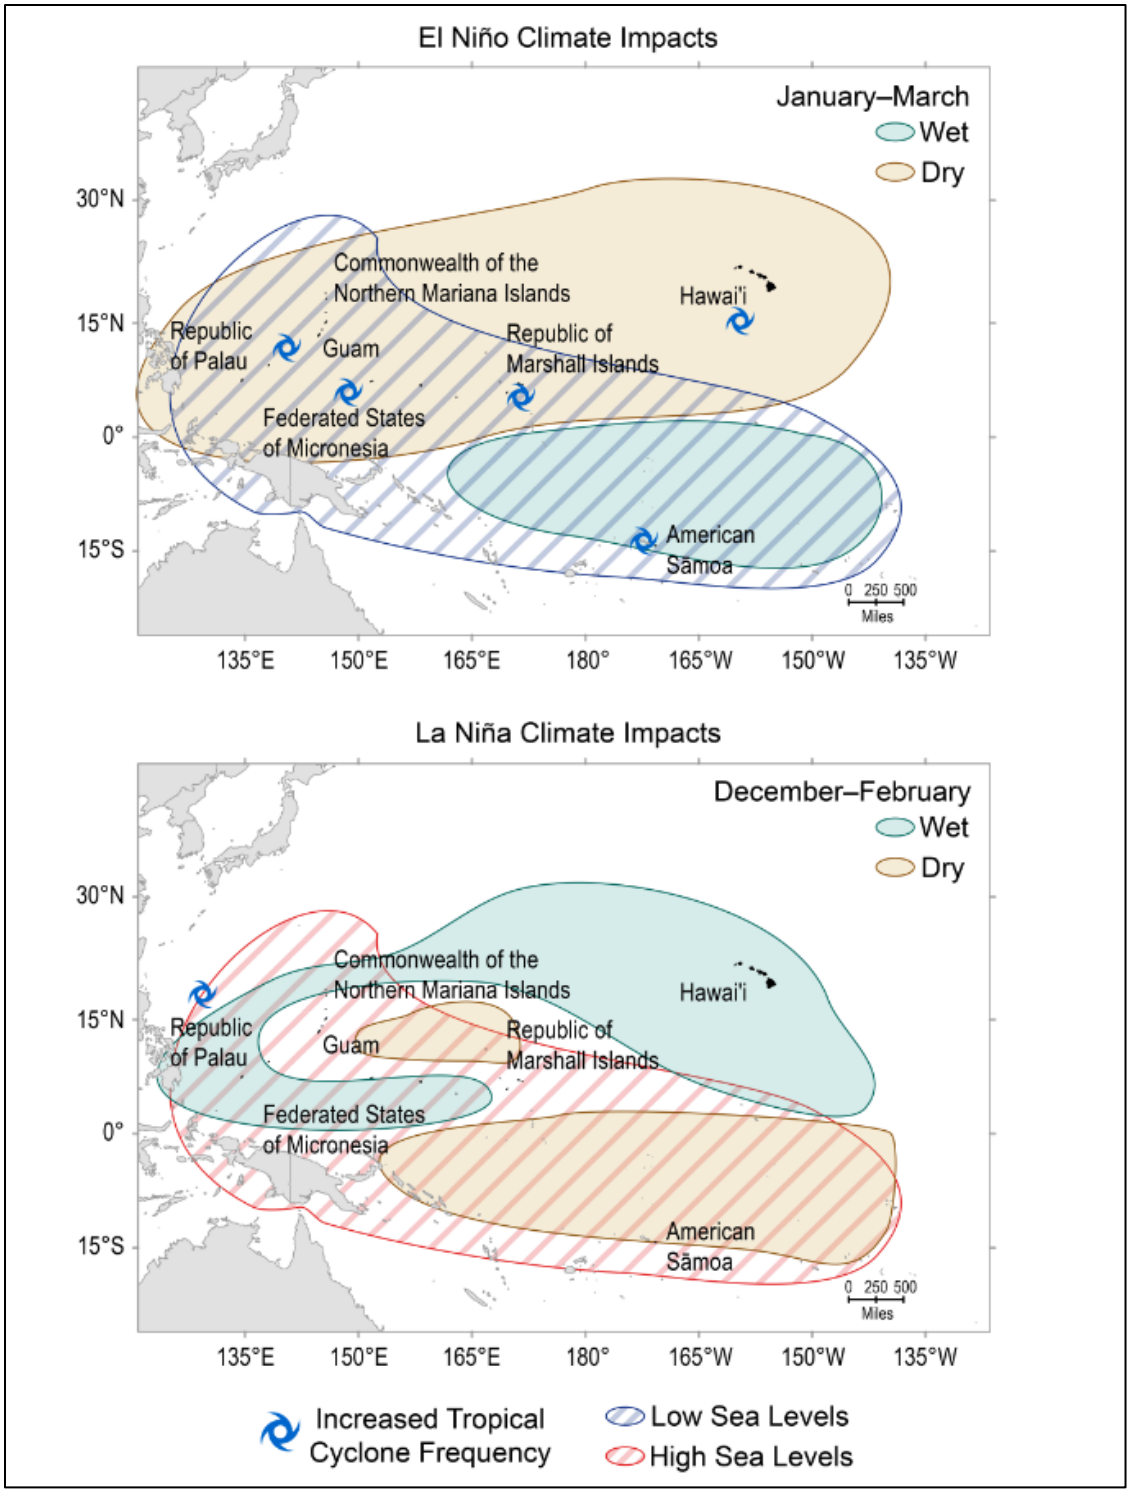

Figure 0.11 Effects on Pacific Ocean Weather of Prior-Year El Niño and La Niña events.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

If both the “drier” and the “stormier” tendencies are in effect immediately following an El Niño event, then the year’s “late rainy season” months are likely to see alternating bouts of wet and dry weather in general, with both effects occurring together (in the same rainy season), immediately after the El Niño extreme of the cycle.

5. Tropical Cyclones: Frequency and Intensity

The way climate change alters the frequency and intensity of tropical cyclones is complex. Riehl (1949) reviewed historical evidence along all the Hawaiian Islands, noting that “The larger the rainfall the greater becomes the relative homogeneity of storms. As storm intensity increases, the importance of orography declines.” However, tropical cyclone frequency and intensity in the central Pacific are expected to increase. This is in part due to:

1. changes in tropical cyclone tracks
2. increased formation of tropical cyclones near Hawai‘i
3. weakening of the vertical wind shear that typically tears tropical cyclones apart as they approach the islands
4. greater frequency of ENSO occurrences (Keener, et al., 2018).

A physically based empirical model analysis in 2013 revealed that the primary cause for an increased tropical cyclone frequency around the Hawaiian Islands was due to storm tracks shifting northward in the open ocean southeast of the island (Murakami, Wang, Li, & Kitoh, 2013). The study also found two other causes for an increased frequency of tropical cyclone occurrences:

1) tropical cyclone formation in the open ocean east of the Hawaiian domain is expected to increase; and
2) a projected change-in-track effect off the coast

of Mexico (tropical cyclones that form there are more likely to propagate into the Hawaiian domain).

Tropical cyclones are expected to make landfall more frequently and with greater intensity in Hawai‘i due to the loss of a “vertical wind shear” that typically tears them apart as they approach the islands. In Hawai‘i, strong northeasterly trade winds flow in the opposite direction of the westerly winds aloft in the upper atmosphere. The effect – a “vertical wind shear” – essentially tears apart approaching tropical cyclones before they can make landfall. However, this wind shear is simulated to weaken. Under the assumption that CO_2 concentrations are doubled, model simulations show an approximate doubling of the risk of landfalling tropical cyclones in Hawai‘i (Grabowski M., 2020).

El Niño events typically result in an increased risk of tropical storms landfalling, as storms form closer and move towards the islands more easily. The number of ENSO occurrences is also expected to increase, as discussed in the previous section. The most active hurricane season through 2022 in the Central Pacific was 2015 (a strong ENSO season), with 8 hurricanes and 6 additional tropical storms (NCEI, 2022).

6. Inter-Annual Variability (IAV) in Sea-Level Measurements

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Inter-Annual Variability (IAV; water surface fluctuations in the ocean) is caused by irregular fluctuations in coastal ocean temperatures, salinities, winds, atmospheric pressures, and ocean currents).

NOAA (2022) indicates that ENSO is a large factor in the IAV of Pacific Ocean stations.

Like individual storms, the IAV provides an extra factor that confuses the gentle rises and falls of the ocean due to the gravitational effects of the sun and moon, and so it is quantified by observation of the combined effects and subtracting out these known tidal effects.

The observed effect of IAV will be examined later in this report (for example, in Figure 0.15 in the section on Sea Level Change).

7. Streamflow

7.1 Streamflow Observations

Oki et al (2010), in USGS Scientific Investigation Report 2010-5035, summarized how the number of monitored USGS stream gaging stations in Oahu had fluctuated. There were 24 in 1957; 36 in 1971; 41 in 1994; 24 in 2008; 27 in 2010. The available data was consequently limited, with few records longer than 20 years. Given the sparsity of data, Oki et al (2010) divided Oahu into only 2 regions for purposes of generating estimates of n-year peak flows at ungaged sites, where n varied from 2 to 500. The Ala Wai GRR canal project has a focus on return periods up to Q_{100}, and mostly at or below the Q_{50} flow. Although various factors were considered in preparation of the regression equations, such as the underlying geology, soil types, vegetation cover, the maximum 48-hr precipitation with return period 2-years or 5 years, and elevation, the selected regressions were based on drainage area and mean annual precipitation, with standard errors of prediction ranging from 40% to 51%, and coefficient of determination R^2 ranging from 0.73 to 0.77. The analysis did not appear to take into account the possibility of climate change.

The Oki et al (2010)-derived regression equations for Oahu's leeward side are shown in Table 0.2. The Ala Wai project is on the leeward side. It is unclear what PRECIP values would be appropriate since there are three parallel streams, each of which includes some area at various rainfall values (as shown previously in Figure 0.8 and Figure 0.9). (Table 0.2 and Figure 0.12) demonstrate the relative insensitivity of the peak flow at the Ala Wai catchment to relatively large (+/- 10%) changes in annual precipitation.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Table 0.2 USGS Expressions for Peak Flows in Oahu (from Oki et al, 2010). Drainage Areas are in square miles; annual precipitation is in inches; regression flows are calculated in cubic feet per second.

USGS Expressions for Peak Flows in Oahu (from Oki et al, 2010). Drainage areas are in square miles; annual precipitation is in inches; regression flows are calculated in cubic feet per second.

Oahu Leeward Region: Regression Equation • For DRNAREA 0.56 to 45.1 sq mi; • For PRECIP 31.9 to 252 inches per annum	Standard error of prediction, in percent	R^2	Standard model error, in percent
Q_2 = 2.339 (DRNAREA $^{0.679}$) (PRECIP $^{1.113}$)	51	0.74	48
Q_5 = 17.58 (DRNAREA $^{0.668}$) (PRECIP $^{0.820}$)	42	0.76	40
Q_{10} = 49.09 (DRNAREA $^{0.664}$) (PRECIP $^{0.674}$)	40	0.77	38
Q_{25} = 145.2 (DRNAREA $^{0.657}$) (PRECIP $^{0.520}$)	40	0.76	37
Q_{50} = 290.4 (DRNAREA $^{0.652}$) (PRECIP $^{0.422}$)	40	0.76	37
Q_{100} = 539.5 (DRNAREA $^{0.646}$) (PRECIP $^{0.335}$)	41	0.75	38
Q_{500} = 1,841 (DRNAREA $^{0.633}$) (PRECIP $^{0.162}$)	44	0.73	40

Fletcher (2010) noted that changes in rainfall since the 1940's seemed to be producing corresponding reductions in streamflow, both from stormflow and from baseflow.

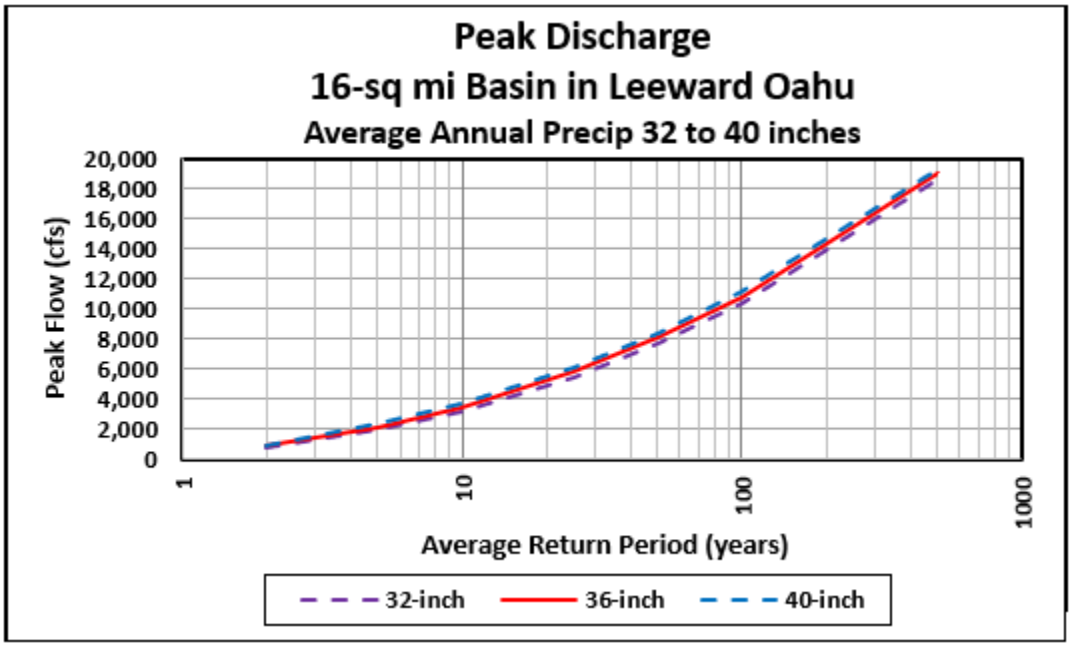

Figure 0.12 Peak Discharge Return Periods for a 16-Square-Mile Drainage Basin, for Annual Average Precipitation 32 to 40 Inches per Year

For a 16-square-mile basin in leeward Oahu (such as the Ala Wai basin), and for assumed annual precipitation of 32 to 40 inches per annum, Figure 0.12 has been prepared to show a range of plausible peak discharge probabilities. As the tight band of results shows, the peak

flow for a 16-square-mile area is not greatly affected by the size of the average annual precipitation. Review of different drainage basin areas leads to a range of expected peak flows, but for the range of annual precipitation rates reviewed, the same pattern of narrow bands from 32 inches to 40 inches applies.

Applying the equation-set of Oki et al (2010), as summarized in Figure 0.12 and Table 0.2, for a 36-inch annual precipitation rate and a range of drainage basin areas, yields the following estimates of flow in cubic feet per second:

- 1 sq mi. Q_2 = 126; Q_5=332; Q_{10}=549; Q_{25}=936; Q_{50}=1,318; Q_{100}=1,792; Q_{500} = 3,290.
- 2 sq mi. Q_2 = 202; Q_5=528; Q_{10}=871; Q_{25}=1,476; Q_{50}=2,070; Q_{100}=2,804; Q_{500} = 5,102.
- 4 sq mi. Q_2 = 324; Q_5=838; Q_{10}=1,379; Q_{25}=2,379; Q_{50}=3,253; Q_{100}=4,388; Q_{500} = 7,912.
- 8 sq mi. Q_2 = 518; Q_5=1,332; Q_{10}=2,186; Q_{25}=3,669; Q_{50}=5,112; Q_{100}=6,867; Q_{500}=12,270.
- 10 sq mi. Q_2 = 603; Q_5=1,546; Q_{10}=2,535; Q_{25}=4,249; Q_{50}=5,912; Q_{100}=7,931; Q_{500}=14,130.
- **16 sq mi. Q_2 = 829; Q_5=2,116; Q_{10}=3,463; Q_{25}=5,786; Q_{50}=8,032;** Q_{100}=10,750; Q_{500}=19,030.
- 20 sq mi. Q_2 = 965; Q_5=2,465; Q_{10}=4,116; Q_{25}=6,699; Q_{50}=9,290; Q_{100}=12,410; Q_{500}=21,910.

The estimates were corrected to the nearest full cubic foot per second, or, for larger results, to 4 significant figures, in keeping with the precision of the Oki et al (2010) equation coefficients. The flow estimates of greatest concern for the current (GRR) study are in bold font; the earlier 2021 FRM Validation Report had a wider focus extending to the 500-year peak flow.

USACE (2015) reported studies by Oki (2004) (16 stations on four Hawaiian Islands, reviewed for changes in flow 1913 to 2002), Mair and Fares (2010) (Makaha Valley in the Ala Wai watershed, where flow records reviewed 1960 to 2008, showed how before 1994 only 9 days per year of zero-flow were typically recorded, but that this had increased to 157 days per year of zero flow for the period 1994 to 2008) and Bassiouni and Oki (2013) (records reviewed 1913 to 2008); USACE (2015) concluded that “There are limited studies for observed hydrological trends. The studies that do exist are in general consensus that there is a long-term, downward trend in baseflows and total flows in streams. The detected shift and long-term trends reflect region-wide changes in climatic and land-cover factors.”

Stevens et al (2022) noted in the NOAA climate summary for the State of Hawaii: “Extreme precipitation events have become less frequent for Kauai and Oahu but more frequent for the Island of Hawaii,” but their report was not definitive about the likely frequency or likely size of flooding in streams.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

7.2 Streamflow Projections

USACE (2015) reported that Hagemann et al (2013) applied three GCMs across two emission scenarios to seed eight different hydrologic models for projecting precipitation, evapotranspiration and runoff on a global scale. For the Hawaii region, the results showed an overall increase in runoff of approximately 160 to 200 mm/year (~6.5 to 8 inches/year) for the 2071-2100 planning horizon compared to the years 1971-2000), assuming an A2 emissions scenario. The USACE (2015) summary was stated as an ensemble of 3 GCMs and 8 GHMs. The USACE (2015) summary did not state what the second assumed emission assumption was, but B2 is likely.

USACE (2015) reported that Doll and Zhang (2010) worked with a similar suite of several GCM models with emission assumptions stated as A2 and B2. Their report showed mild (relative to global results) impacts to Hawaii, for both low and average flows, which were expected to decrease by 10 to 20% by the authors' planning horizon target of 2055.

In a study focused on "the mountainous Hawaii watershed", Safeeq and Fares (2012) reviewed models of evapotranspiration and streamflow. On the basis of climate scenarios, their model predicted a range of -51% to +90% for change in the annual streamflow over a 43-year modeled period (ending in the middle of the 21st century).

Both USACE (2015) and CDM Smith (2012) cautioned that hydrologic parameters were a significant source of uncertainty.

8. Sea Level Change

A model of expected inundation for the area of interest is shown in Figure 0.13. The influence of the coastline is clear in the aerial view. The 0.1 AEP (10-year) inundation map was prepared during the RAS modeling effort to define the end of the channel flow area, as defined in the hydraulic model.

More than 40 combinations of floodwalls, flapgates, levees, tunnels and pumpstations were reviewed; the team's tentatively selected project (TSP) has been selected based on expected conditions through 2080, with acknowledgement that in the event of even higher water levels (more from relative sea level change RSLC than from riverine flow changes) the design should be adaptable to the changes (wider levees and floodwalls at which vertical additions would be feasible. All alternatives were modeled and assessed in terms of geotechnical, structural, construction, real estate requirements, constructability, and costs. The biggest anticipated change through 2080 was in RSLC. An assessment of different conditions was made assuming higher peak water surface levels than anticipated, and the team took into account the possibility of wider floodwalls that could be raised in the future. Since the site-specific flow data indicated small decreases in annual peak flow year over year, the likely requirement for this change came from RSLC, not from a changed riverine-flooding condition. Given the early stage of design (less than 30% design complete), these features of resilience are not yet completely incorporated into the designs.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

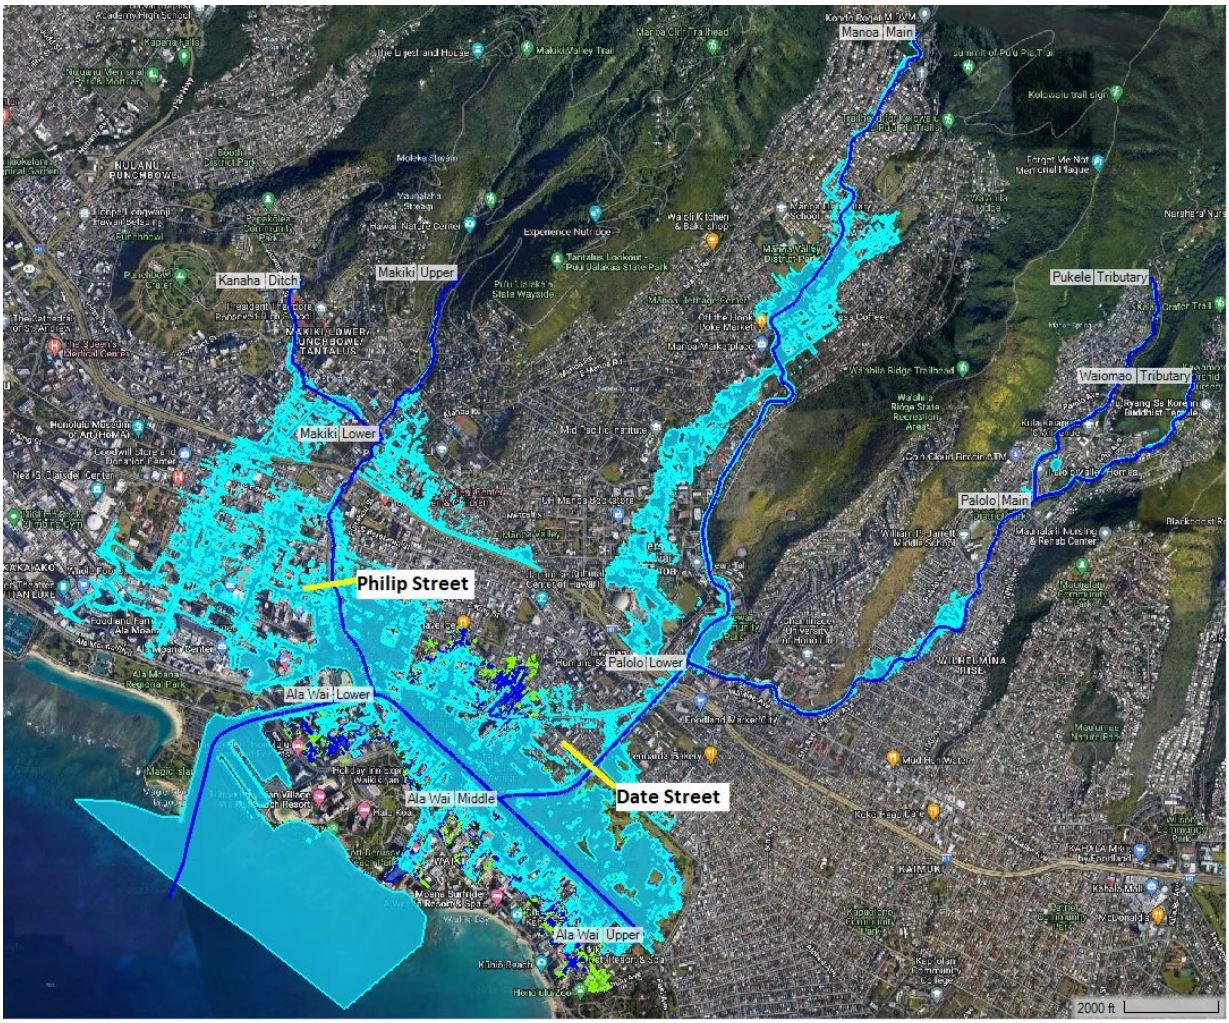

Figure 0.13 Current Study: 2080 FWOP 0.10 AEP (10-year) fluvial flood with various downstream boundary conditions (intermediate SLC and IAV for MHHW (cyan color), 0.99 AEP (1 year) (flooding beyond MHHW in blue color), and 0.50 AEP (2 year) (flooding beyond MHHW in blue color), and 0.50 AEP (2 year) (flooding beyond MHHW and 0.99 AEP tidal in green color). Yellow lines: tidal limit on the Makiki Stream (Philip Street) and Manoa-Palolo Canal (Date Street)

It is noted that the 10-year inundation map presented includes a section of the Manoa Stream in which the river breaks its banks to flow along a parallel route for about a mile through city streets before rejoining the river at a location downstream of its confluence with the Palolo, but upstream of the gage location. Similarly, the western tributary (itself comprising Kanaha and Makiki streams) gives rise to inundation outside their respective streambanks/channel banks. This projection is reviewed in greater detail in the H&H appendix, in its Ala Wai Flood Risk Management General Reevaluation Study: HEC-RAS Boundary Conditions (USACE (2022)). The figure is introduced here in order to show tributary rivers, their approach to the Ala Wai Canal, and the need to incorporate coastal concerns into an overall Ala Wai Canal analysis.

Hawaii's coastline is subject to astronomical tidal vents, with two high tides every 24 hours 50 minutes. These are governed by the gravitational influence of the moon and sun on the oceans. Full moons and new moons tend to coincide with a larger tidal range. For Hawaii, there are six-

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

week periods in June-July and again in December-January when the effects are especially large, corresponding to the earth being farthest from or closest to the sun (University of Hawai'i (2018)).

The potential for future sea-level change, relative to ground levels, to affect the project area was evaluated briefly following ER-1100-2-8162 and ETL 1100-2-01. The ETL prescribes a method for defining three future projections (three sea-level curves) that are used to bound the estimate for sea-level rise (SLR) over time. The sea-level projections (curves) are site-specific and are derived based on the historical sea-level trend (the local sea-level change) blended with the eustatic change (the change in sea-level due to changes in either the volume of water in the world oceans or net changes in the volume of the ocean basins).

The three SLR scenario curves for Honolulu Hawaii were obtained using the CESL SLR web tool, http://www.corpsclimate.us/ccaceslcurves(new)html. The tool defines a lower bound for sea-level rise, an intermediate trend, and an upper bound curve. The sea-level projections examined in this study (Figure 0.14) are based on the National Ocean Service (NOS) Station at Honolulu, Hawaii (Gauge 1612340). Based on the CESL-SLR webtool, the degree of sea level change that may affect the project (at 50 years from 2030) could increase tidal water level elevation by 0.2 ft, 0.8 ft, or 2.6 ft; depending on which of the three scenario curves is applied, from the assumed project start year of 2030. The 2080 estimates corresponded to projected increases in mean sea level above the average mean sea level elevation of the current tidal epoch (1983-2001) of 0.4 ft, 1.1 ft, or 3.3 ft. (The 3.3-ft estimate is approximately equal to 1.0 m). It was noted that the 2080 "design elevation" might be reached as soon as 2040 following the USACE high RSLC projection, or as late as approximately 2180 following the low RSLC projection.

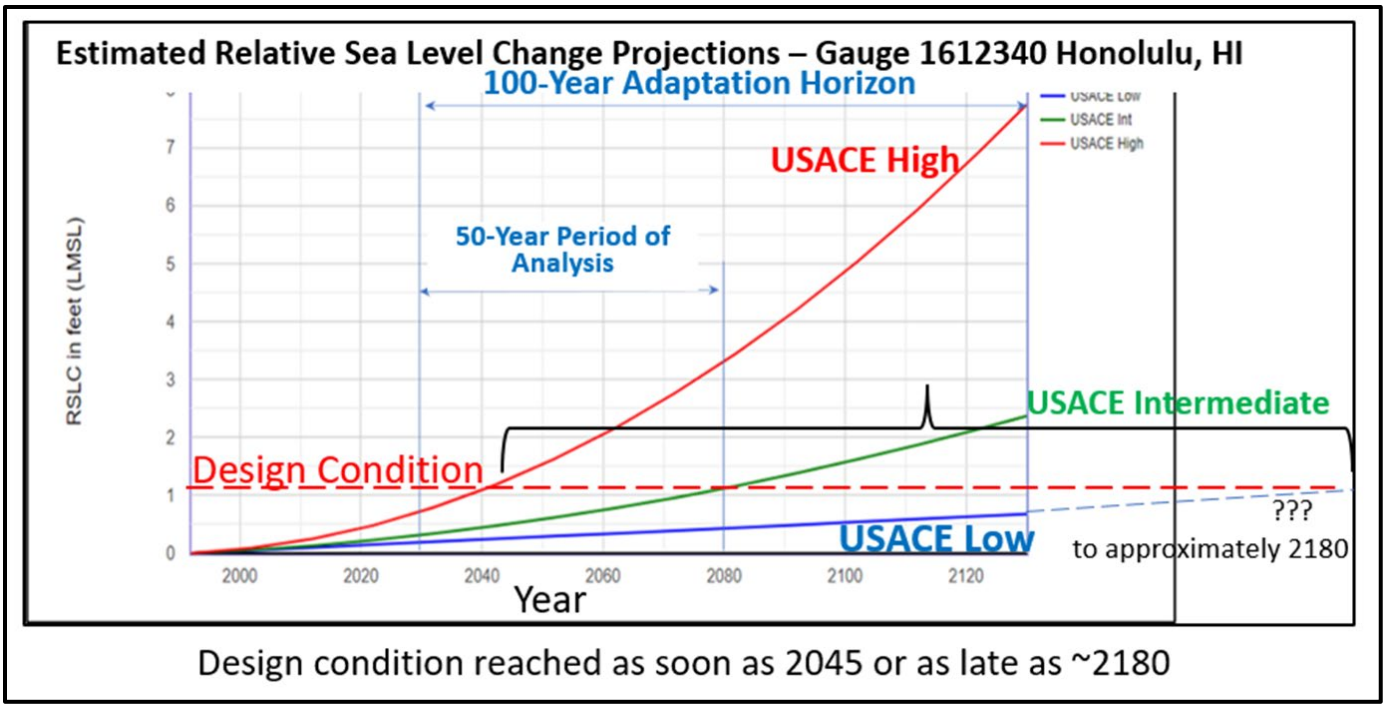

Figure 0.14 USACE Low, Medium and High Sea-Level Change Projections for Honolulu, Hawaii

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

The three curves in Figure 0.14 were used to inform Table 0.3, in which the **intermediate** and **high** RSLC projections are combined with a typical one-year extreme water level (EWL) and inter-annual variability to generate possible downstream design boundary conditions for the basic FWOP and FWP conditions.

The 50-year period of analysis that is called out in the figure is in keeping with EP 1100-2-1 which acknowledges that, historically, economic forecasts beyond the 50-year time period were not considered reliable.

The 100-year estimate is in keeping with the need to cover the 100-year period through 2130 is consistent with the need laid out in EP 1100-2-1 for projections through a recommended 100-year epoch of analysis.

Table 0.3 Projected Downstream Water Levels including SLC, EWL and IAV (ft, MSL)

Year	USACE Low	USACE Intermediate	USACE High	USACE Int + EWL (0.99 AEP)	USACE High + EWL (0.99 AEP)	USACE Int + EWL (0.99) + IAV
1992	0.00	0.00	0.00	1.61	1.61	2.10
2030	0.20	0.33	0.72	1.90	2.33	2.40
2035	0.23	0.39	0.89	1.97	2.49	2.46
2040	0.23	0.43	1.08	2.03	2.69	2.53
2045	0.26	0.52	1.31	2.10	2.92	2.59
2050	0.30	0.59	1.54	2.17	3.15	2.66
2055	0.33	0.66	1.77	2.26	3.38	2.76
2060	0.33	0.75	2.07	2.33	3.67	2.82
2065	0.36	0.82	2.33	2.43	3.94	2.92
2070	0.39	0.92	2.62	2.53	4.23	3.02
2075	0.39	1.02	2.95	2.62	4.56	3.12
2080	**0.43**	**1.12**	**3.31**	2.72	4.92	**3.22**
2085	0.46	1.21	3.67	2.82	5.28	3.31
2090	0.49	1.35	4.04	2.92	5.64	3.41
2095	0.49	1.44	4.43	3.05	6.04	3.54
2100	0.52	1.57	4.86	3.15	6.46	3.64
2105	0.56	1.71	5.28	3.28	6.89	3.77
2110	0.59	1.80	5.74	3.41	7.35	3.90

2120	0.62	2.10	6.69	3.67	8.30	4.17
2125	0.66	2.23	7.22	3.81	8.83	4.30
2130	0.69	2.36	7.74	3.97	9.35	4.46

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

The 2080 target date is highlighted in the table, where the expected RSLC increase for the year (1.12 feet above the current LMSL, intermediate curve) was combined with the surge and IAV fluctuation condition to generate an estimate that the BC should be 3.22 feet above the current LMSL.

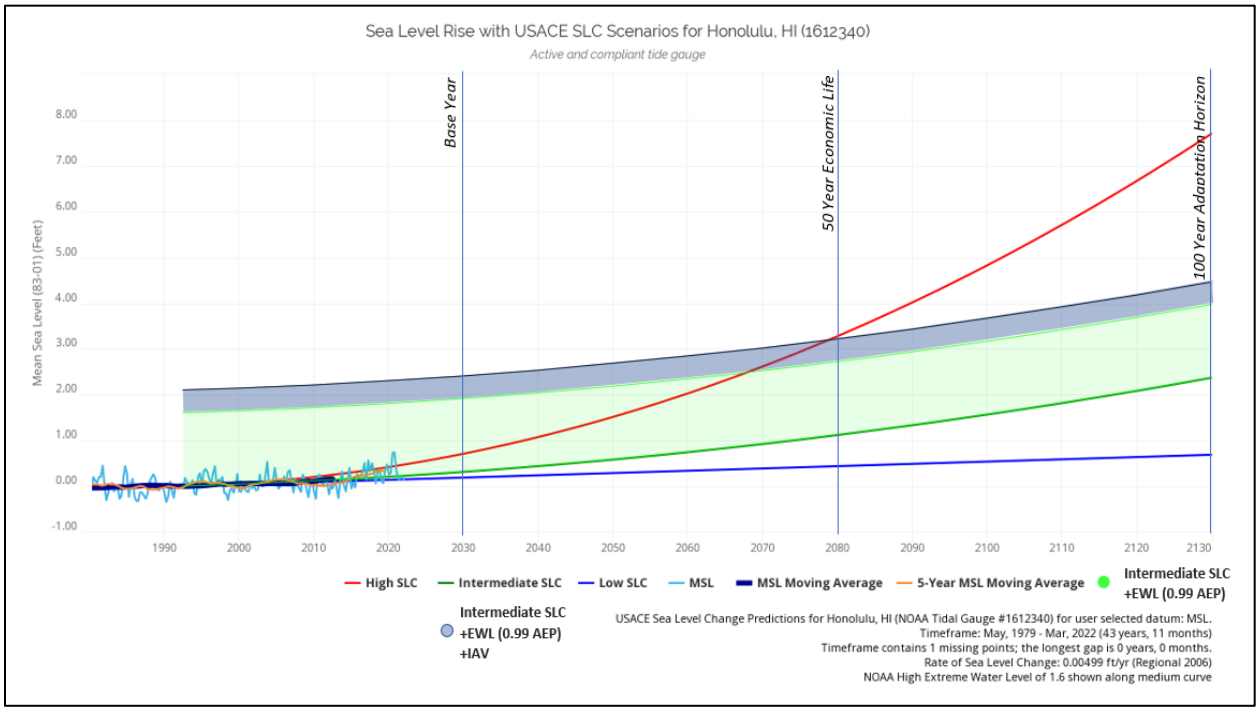

Figure 0.15 USACE Sea Level Tracker 1980-2130 including estimated Future Project Boundary Conditions

Review of Figure 0.15 shows that if the shaded regions were above the red (high) curve instead of the green (intermediate) curve, the 50-year design condition would be reached in about 2045 (LMSL with IAV and a 0.99% annual surge condition). For the projections through 2080, the difference in excess of RSLC due to extreme water level and interannual variability is 2.2 feet. Hydraulic modeling was conducted to develop an understanding of sensitivity of inundation to different rates of RSLC. The 2.2-ft elevation difference, the TSP through 2080 appeared to be adequate through a 20-year flood event.

An even higher BC was examined, in which the high-rate curve was extended through 2100, and the FWP and FWOP results indicated 0.8 ft to 1.7 ft of reduction in inundation for modeled storms up to the 20-year event, for the one test location that was examined in detail (See Table 0.4). A more complete review of elevations and velocities throughout the basin area is possible, based on the modeling that has been completed, but the elevations reviewed, for the tidal assumptions made, were taken as indicative of likely results and adequate for a sensitivity analysis in support of the review of alternatives. The analysis does not constitute a full uncertainty analysis, but the BC selections made do serve to indicate the likely changes that might be seen in the event of a different RSLC rate, over a plausible range of values.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Fletcher (2010) prepared a climate change summary for Hawaii, reporting the expected rise of about 1 meter (about 3 feet) in expected sea-level during the 21st Century. The area around the Ala Wai Canal that was below the expected high tide under this scenario was depicted in one of his illustrations. The area was similar to the area of concern for the current project.

See Figure 0.16.

Figure 0.16 Details from Fletcher (2010). Fletcher added the blue line to show the expected level of the high tide at the end of the 21st century.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

A review of the timing of high water level events in relation to high streamflows was conducted for the Manoa-Palolo Gauge and the Honolulu tidal gauge situated near to (2 miles west of) the project. The water level time series and streamflow series datasets were found to be independent variables, removing the need to develop a joint probability. Figure 0.17 is presented to demonstrate the lack of any relation between high water levels and high streamflows.

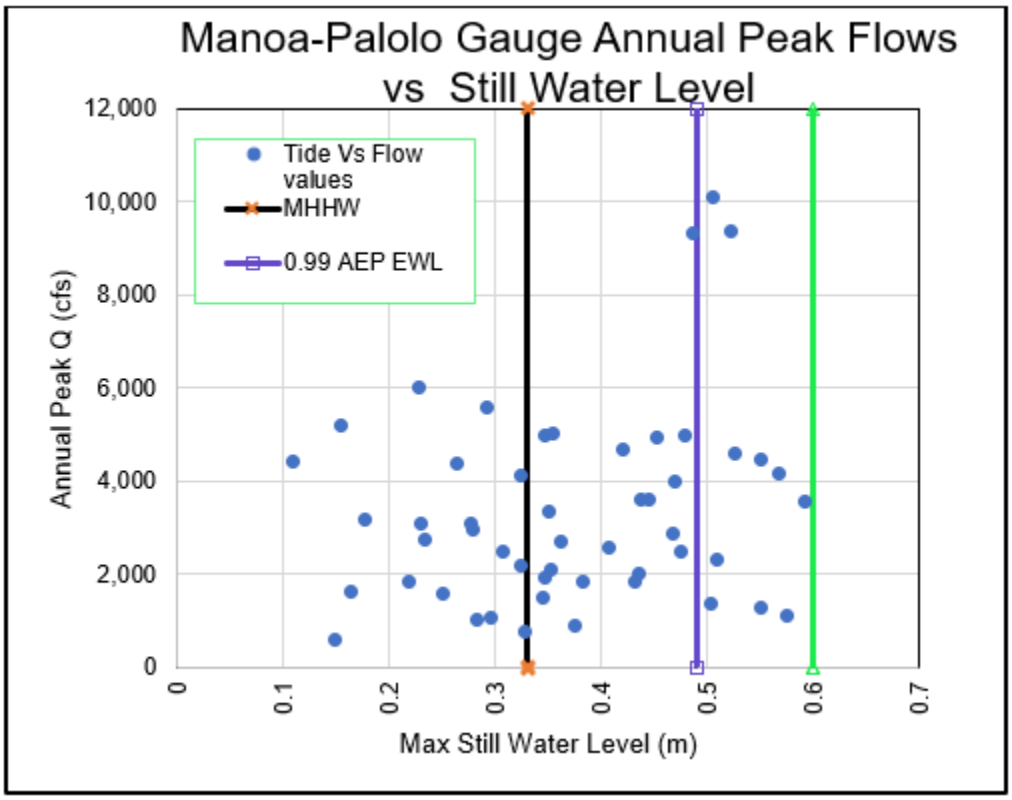

Figure 0.17 Manoa-Palolo Gauge Annual Peak Flows vs Still Water Level

Based on the review of the relative concurrence of high runoff flows and high water level events, no relationship is apparent between these two phenomena. Most high runoff events occur when water level elevations are less than the 0.99 AEP elevation: for the Manoa-Palolo watershed, 39 of 51 events (76%) occurred when still water levels were less than the 0.99 AEP Extreme Water Level (100-year high tide level).

The analysis summarized in Figure 0.17 reviews high tide (maximum still water level) in conjunction with annual peak flow. Table 0.3 and Figure 0.15 present water levels that include storm induced rises in water level such as surge and wave action.

Modeling of combinations of downstream boundary conditions shows that upstream water surface elevations are not sensitive to the downstream boundary condition; and the coastal water level influence is limited to the lower, flatter portion of the watershed less than 0.5 mile from the canal, with limited influence when streamflow exceeds the AEP=0.05 (20-year) case, because of the steepness of the watershed. For the computed 2-year modeled storm events, the coastal water level effect extends to Fern Street at only 1,300 feet upstream of the Ala Wai

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Canal; for larger modeled storms up to the 20-year storm, assuming the intermediate RSLC curve up to the estimated 2130 mean sea level, the differences due to sea level extend as far as Phillip Street, at 2,300 feet (0.44 mile) upstream of the Ala Wai Canal.

Initially, therefore, the team determined by sensitivity analysis that the two sources of flooding could be mitigated-for safely as separate exercises.

It was noted however that any future change in the rate of RSLC was not captured in the analysis performed. Consequently, FWOP and FWP hydraulic modeling was repeated for the same fluvial cases (5, 10, and 20-year storms), for two new assumptions concerning boundary conditions, resulting in three sets of results: a downstream boundary condition at assumed MSL 3.22 ft, a second set for BC at 5.41 ft, and a third BC at 6.30 ft.

Reference was made to the observed RSLC at Honolulu. The team reviewed available data since 1922 and observed that both the 5-year MSL moving average trend and the 19-year MSL moving average appeared to be oscillating about the intermediate SLC curve (See Figure 0.18).

A “baseline” condition was computed for the boundary condition, taken as a combination of the intermediate RSLC curve for the year 2080, with additional elevation for a 10-year storm surge and inter-annual variation IAV.

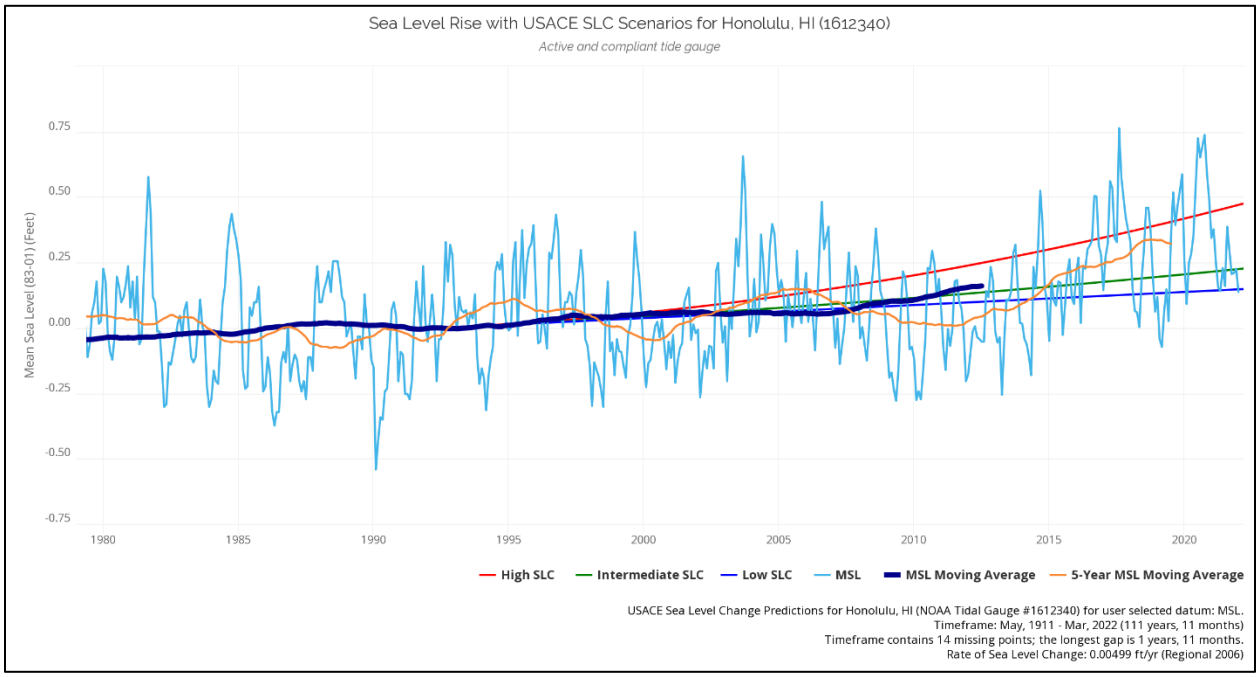

Figure 0.18 Historic Relative Sea Level Change 1980-2022 (US Army Corps of Engineers, n.d.)

The project team reviewed the 0.99 Annual Exceedance Probability (1-year) Extreme Water Level, including the **intermediate** Sea Level Rise and Inter-Annual Variability, for a project economic life (**2080**) still water level elevation of 3.22 ft-LMSL. Sensitivity to sea-level rise was reviewed using two larger downstream pool levels: 5.41 ft and 6.3 ft as the receiving water level boundary condition. These correspond to: firstly, the same set of parameters, but assuming the

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

high-RSLC scenario were to occur, for the same 2080 target year (5.41); and secondly, the same set of parameters assuming the **high**-RSLC scenario were to occur, but extending the projection **through 2100**. For the sensitivity study, the FWOP and with-project water levels were estimated for three storm cases: 20%, 10%, and 5% (5-year, 10-year, and 20-year storms). These results are summarized in Table 0.4 (with reference to one cross-section located immediately upstream of the inflow from the Makiki Stream/Canal) and Figure 0.19, Figure 0.20, and Figure 0.21.

Table 0.4 Inundation Levels' Sensitivity to Projected RSLC and Storm Events up to 5% Storm at the confluence of Makiki Canal and Ala Wai Canal

Fluvial Flood Event		Down-stream	Future Without Project (FWOP)			Future With Project (FWP)		
AEP (%)	Avg Return Period (years)	Boundary Condition Elevation (ft MSL)	Left Over-bank	Channel	Right Over-bank	Left Over-bank	Channel	Right Over-bank
20%	5-yr	3.22	4.67 *	4.57	5.1	-	-	-
10%	10-yr		5.37 *	5.03	5.62	-	-	-
5%	20-yr		5.76 *	5.48	6.04	-	-	-
20%	5-yr	5.41	6.02	6.00	6.08	-	6.45	5.32
10%	10-yr		6.26	6.27	6.50	-	6.86	5.77
5%	20-yr		6.50	6.52	6.93	-	7.23	6.09
20%	5-yr	6.30	6.67	6.70	6.91	-	7.17	5.46
10%	10-yr		6.86	6.90	7.23	-	7.51	5.89
5%	20-yr		7.03	7.09	7.56	-	7.85	6.19

- Elevations are stated for one key location immediately upstream of the confluence of Ala Wai Canal and the Makiki Stream Canal.
- The asterisk symbol * is used to denote partial flooding on the left overbank. Inundation on the left overbank is absent from FWP computer runs, even when the downstream BC is set to 6.30 (3.08 feet higher than the 2080 FWOP condition, corresponds to the estimated condition for a 1-year event with IAV, set for the year 2100 assuming the “high” curve for RSLC.
- For the three storm events (5, 10, or 20-yr) with the two “elevated” BC assumptions (5.41 to 6.3 feet), the level of inundation on the right overbank is reduced by 0.7 (smaller storms) to 1.6 feet (larger storms).
- The TSP project is protective with the 5.41-ft water level BC to generate approximately the same right-overbank results as for the FWOP condition with only 3.22-ft BC water level.

The table summarizes the water levels with or without the project, for the two higher water levels, at just a single point in the system (one cross-section and two related overland water stations at the confluence of the Makiki Stream/Canal and the Ala Wai Canal). The maps in Figure 0.20 and Figure 0.21 show the differences between the two model runs on a more system-wide basis. Although the simulated water levels in the FWP condition rise in the canal itself relative to the FWOP condition, the proposed changes limit the quantities of water that enter the overbank area, and so inundation and flooding are reduced.

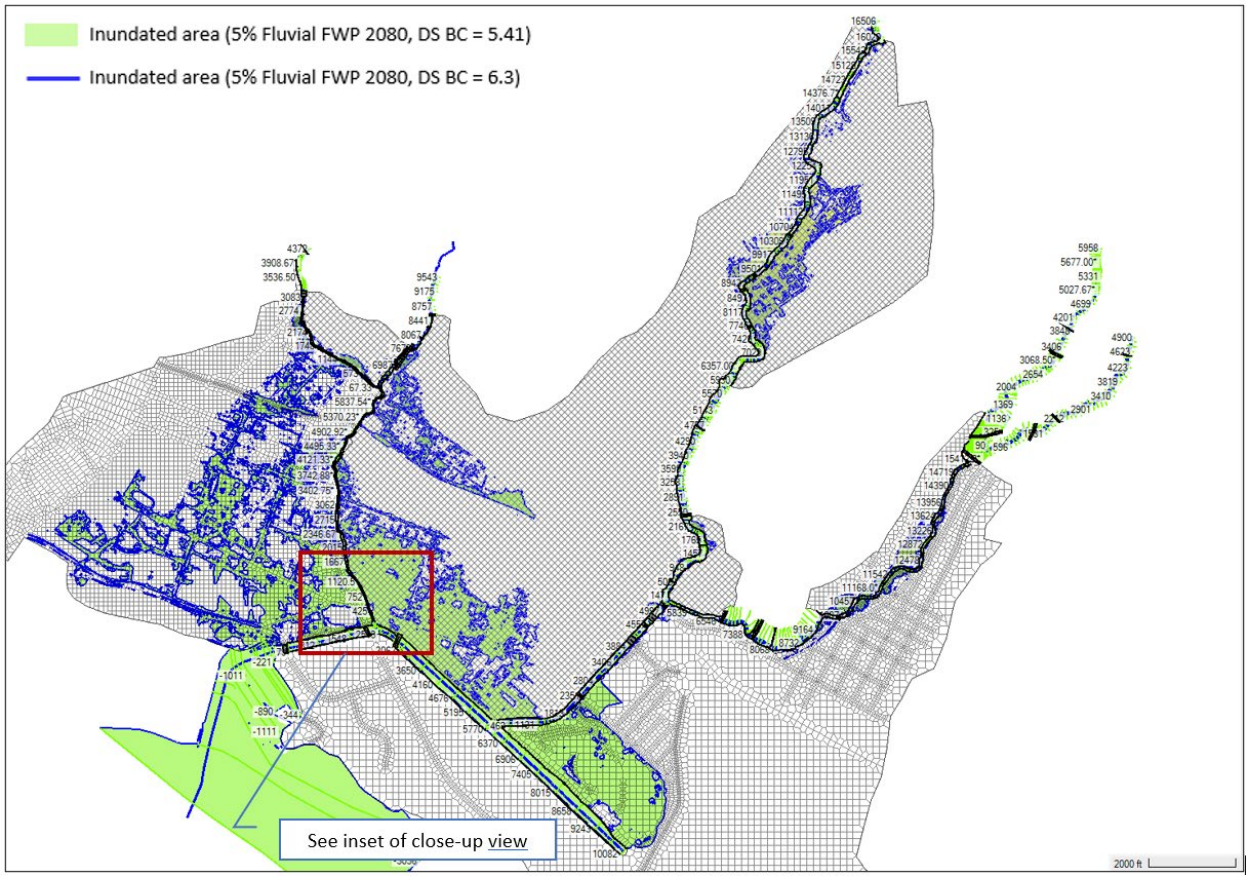

Figure 0.20 Ala Wai Modeled System View

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

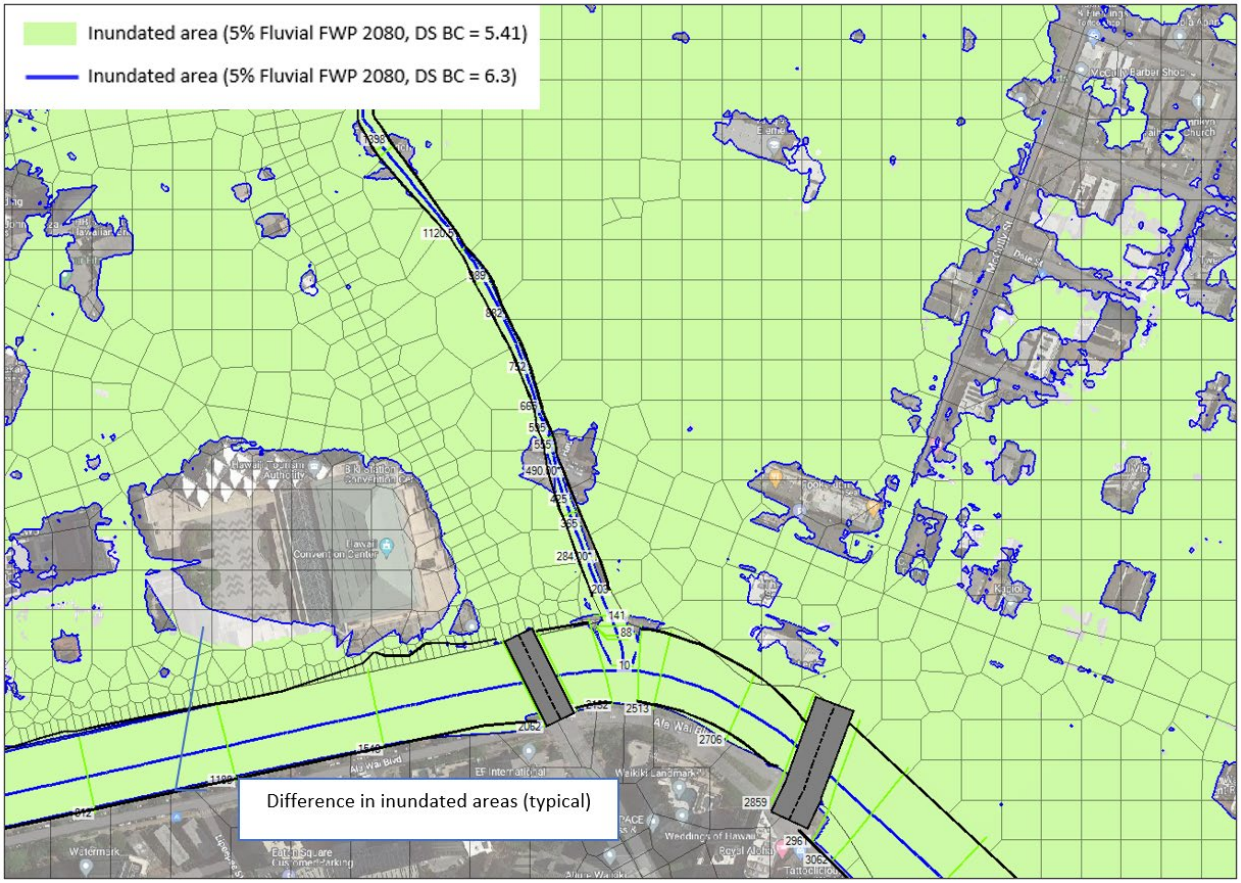

Figure 0.21 Ala Wai Modeled System View – "Inset/Close-up" Details at the Confluence of Ala Wai Canal and Makiki Canal

There is potential overlap between the inundation areas under the Fletcher (2010) projected inundation region and the various GRR alternatives for a final array. The alternatives are summarized below.

The costs estimated in 2023 did not include the costs of any utility or facility relocations or non-structural alternative measures.

1. **Alternative 1 – Storage Cornerstone (storage).** Includes 5 main storage areas (detention at Makiki Park and Tennis courts; detention at Manoa Valley District Park; detention at Ala Wai Golf Course; detention at Kapiolani Park; detention at Kaimuki High School.) The golf course and Kapiolani Park are likely inside the Fletcher (2010) area of tidal rise.
   *A real estate assessment in 2023 indicated that **real estate purchases** associated with this alternative, along with easements and temporary access during construction, would cost about $30 million.*

2B. Alternative 2B – Conveyance Cornerstone (floodwalls). Capacity increases at Woodlawn Bridge and at the Ala Wai canal itself. The timing of the increased riverine flow during a flood would remove water ahead of inundation in the tidally influenced area. It should be noted that the Ala Wai floodwall part of the design is inside the Fletcher (2010) increased high tide assessment.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

*An initial real estate assessment in 2023 indicated that **real estate purchases** associated with this alternative, along with easements and temporary access during construction, would cost about $9 million.*

2C. Alternative 2C – Conveyance Cornerstone (Second outlet at the east end of the canal). Timing of the increased flow would remove water ahead of inundation in the tidally influenced area. It should be noted that this extra outlet is inside the Fletcher (2010) increased high tide assessment, and requires some storage measures around the canal.

*An initial real estate assessment in 2022 indicated that **real estate purchases** associated with this alternative, along with easements and temporary access during construction, would cost about $121 million. The alternative was not pursued for a subsequent more detailed cost estimate in January 2023.*

5. Alternative 5C – Hybrid alternative (TSP). For a more complete description, the reader is referred to the hydraulic appendix. This alternative is the tentatively selected plan (TSP) and so it is described in greater detail than was used for the previous summaries (1, 2B, 2C). The alternative includes a 6-ft-high, 1,270-ft-long floodwall with a closure structure (gate) at Woodlawn Drive in the Manoa Valley, along the right bank of Manoa Stream, upstream of the University of Hawaii. There would be a 6-ft-high, 2,510-ft-long floodwall at the confluence of Manoa and Palolo Streams, following the alignment of Koali Road, with two concrete drainage structures to provide interior drainage of stormwater flows from the residential neighborhood behind the Koali Road floodwall. The Koali Road floodwall design would include two road closure structures and installation of flap gats on two smaller culverts. At the Ala Wai Golf Course, an earthen levee of height 6 to 9 feet and length 10,176 feet would be constructed to create a detention basin at the facility. The design would allow for erosion control as water entered the golf course, and four concrete drainage structures with three flap gates would allow collected stormwater to drain slowly into Ala Wai Canal. A new floodwall would be constructed, tying into the levee embankment, up to 9 feet high, with one road closure structure, one drainage structure, and a canoe access point. At the Ala Wai Canal, a 6-ft-high, 22,852-ft-long floodwall would be constructed, with 59 of the existing storm sewers retrofitted with flap gates, and a further 14 to remain in service as drainage structures. There would be eleven road closures and three canoe access points. The design includes an elevated walking path in the Manoa-Palolo Canal area. Where the Makiki Stream enters the Ala Wai Canal, a 6-ft-high 883-ft-long floodwall with two flap gates, one concrete drainage structure, and four road closure structures would be constructed. *At the time of writing in late August 2023, the exact alignment and height of the structures in and around the golf course were being refined, and details of real estate "takings" remained to be confirmed.* It is noted that parts of the proposed changes would mitigate the inundation region identified by Fletcher (2010). *An initial real estate assessment in 2022 indicated that **real estate purchases** associated with this alternative (in its 2022 draft form), along with easements and temporary access during construction, would cost about $33 million. As this became the team's preferred "Tentatively Selected" project, greater scrutiny was brought to bear on the geometry and costs of this alternative. The resulting **Alternative 5.3** had total real estate purchases of $58.1 million. The increase from 2022 was largely due to changes at the Ala Wai golf course levee, necessary purchase of 5 residential properties, and costs to relocate approximately 100 utility lines (water, sewer, power, gas).*

Review of construction costs, damages, and damages prevented (both dollar costs and life-loss estimates) was performed for 5 alternatives plus the FWOP condition. For the Tentatively Selected Plan (TSP), a further sensitivity analysis was performed to review the likely performance of the with-or-without-project performance under the USACE "high RSLC"

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

condition. In essence, the 2080 estimate of a stillwater of 1.12 ft becomes a stillwater estimate of 3.31 ft (an increase of 2.19 ft). Including storm surge and interannual variability, 2.72 ft rises to 4.92 ft (an increase of 2.20 ft).

In the event that sea level rises at the rate of the USACE intermediate curve assumptions, the design condition is reached in 2080. If the rise proceeds at the USACE high curve rate, the design condition is reached between 2040 and 2045. From Figure 0.22, it appears that the intermediate curve is more realistic. The high curve was used as a reference in the sensitivity review to help establish how the alternatives might respond to more rapid RSLC.

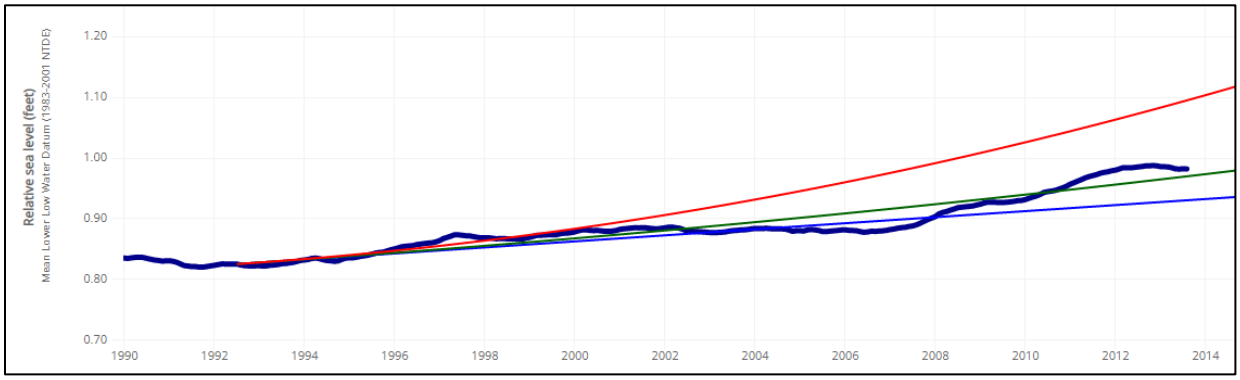

Figure 0.22 Low/Intermediate/High Projections (Mean Lower Low Water) of Relative Sea-Level Rise for Honolulu (projections from 1992)

9. Literature Review Summary

Recent climate literature indicates that there is evidence of observed, increasing mean air temperature trends in the study region. Nightly minimum temperatures are rising more quickly than daily maximum temperatures. Mean temperatures are projected to rise by 2 to 10 °F (1.1 to 5.6 °C) by the end of the 21st century.

Total precipitation and the occurrence of extreme storm events has been decreasing over time. Projections through 2010 indicated that this trend was expected to continue, although more recent studies, especially the NCA4 (2018), indicate that extreme storms may become more frequent. The nature of long-term trends is not easily discerned because of the effects of multiple-year cycles such as ENSO, changes in how winds might track, and changes in how the temperature-changes at altitude might affect the storm patterns.

Streamflow is widely expected to decrease over the 21st century, although there are indications that peak flows might increase. The NCA4 finding of increased stormflow flooding, for example, acknowledges the previous projections of reduced danger from extreme streamflow, but indicates that a more refined analysis of GCMs might indicate not only more droughts, but also more extreme runoff floods.

The USACE literature synthesis findings are summarized in Figure 0.23.

10. Record of Inflows to Ala Wai Canal and Nonstationarity Analysis

The primary objective of this study is to improve the flood risk management posture in the Ala Wai drainage basin area, so the focus of this investigation is the high flow regime that is best represented by annual peak values of the daily average flows.

Major tributaries to the Ala Wai Canal are the Manoa and Palolo Streams and the Makiki Creek. The Manoa and Palolo Streams meet upstream just north of Lunalilo Freeway (Route 1) and then follow a channel south for approximately 4,800 feet before discharging to the Ala Wai Canal, immediately west (downstream) of the Ala Wai Golf Course. The USGS maintains a gaging station on the drainage ditch between the confluence and the outfall/discharge point,

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

about 0.6 miles upstream of the confluence with the Ala Wai Canal. The basin area at this location (16247100-Manoa-Palolo Drainage Canal at Moiliili, Oahu, HI) is 10.2 square miles. There is an unbroken record of peak annual flows since 1968. The NSD tool applies analysis to the period from 1968 to 2021.

Peak annual flows are summarized in Figure 0.24. No nonstationarities were detected in this record. The mean value of the annual peaks is 3,300 cfs; their standard deviation is 2,100 cfs; their variance is 4,400,000 $ft^6\ sec^{-2}$.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

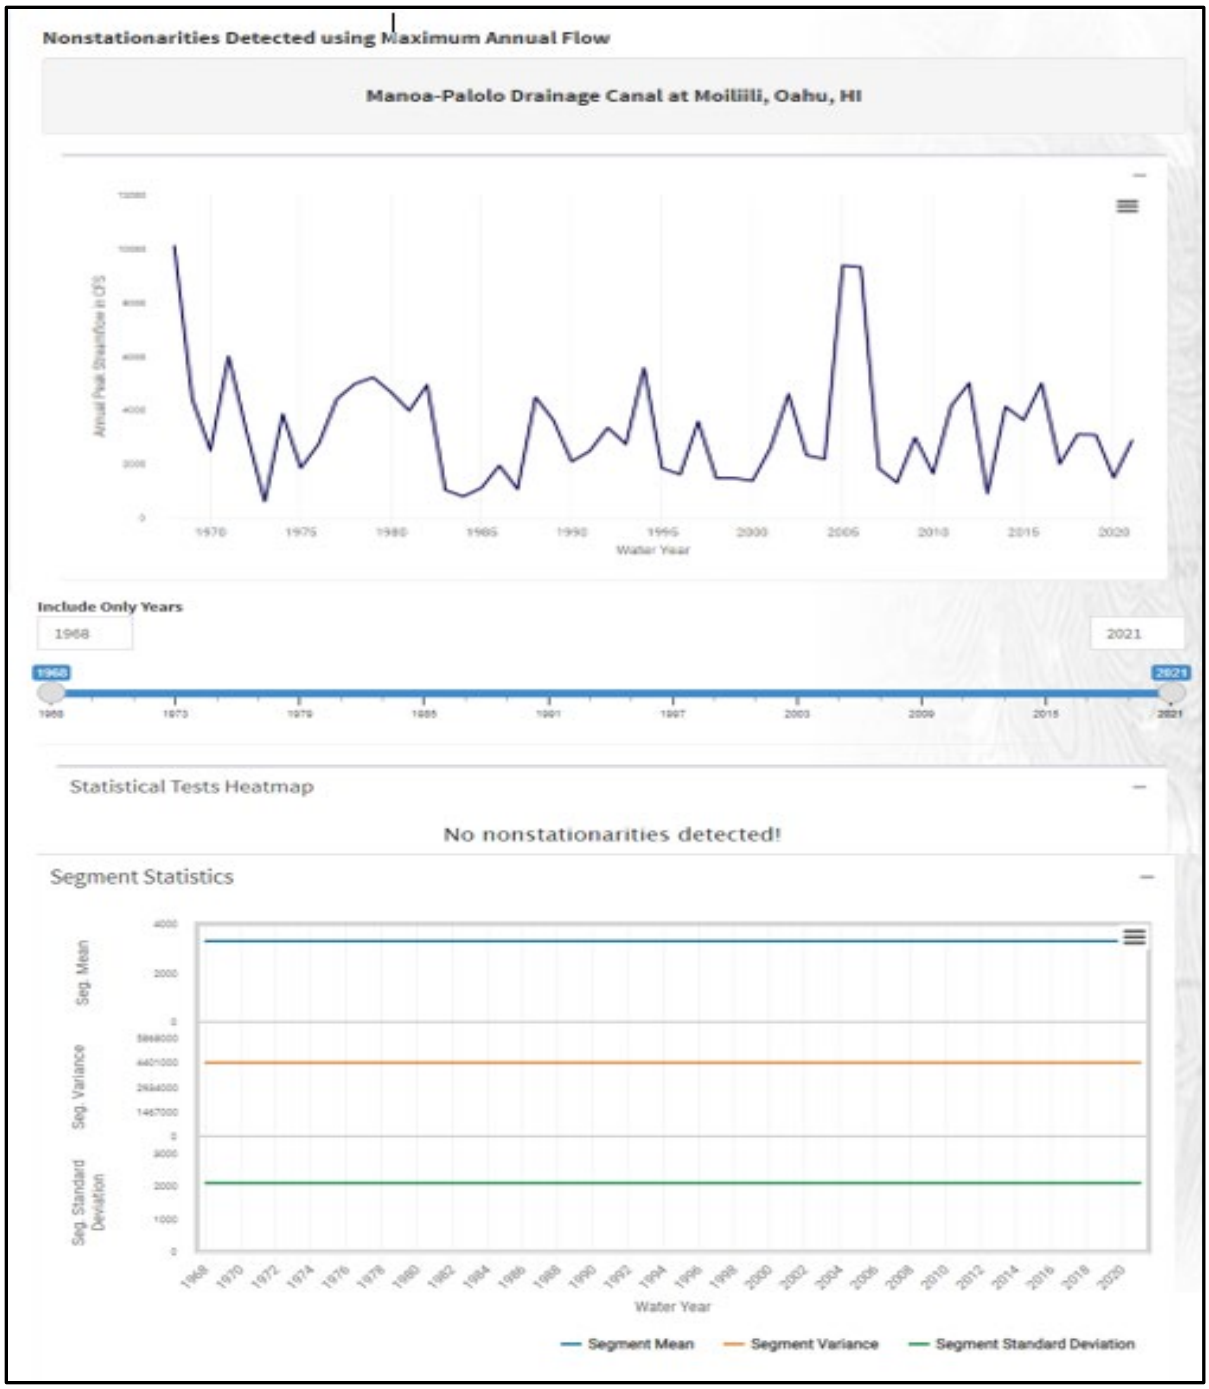

Figure 0.24 Output of the Nonstationarity Detection Tool for Manoa-Palolo Canal at Moiliili, Honolulu, HI. USGS Gage 16247100. The mean value of the annual peaks is 3,300 cfs; their standard deviation is 2,100 cfs; their variance is 4,400,000 ft^6/sec^2.

Additionally, as shown in Figure 0.25, no monotonic trends are detected in the peak streamflow dataset between 1968 and 2021 using the Mann-Kendall (p-value = 0.40>0.05) and Spearman Rank Order (p-value = 0.40>0.05) tests applied using a 0.05 level of significance.

Figure 0.25 Trend Lines and Statistical Summary for Maximum Annual Flow at Gage 16247100 data 1968 to 2021.

Review of available data on the USGS website shows that the gage appears to have been upgraded in late 2004. The USGS record shows a single data point for each day from 1968 through mid-2004. In the first 5 days of September 2004, however, the record for September 2 included 30-minute readings as well as the single data point for the day, and the jerky nature of the record indicates that calibration was in progress. That was the only day with 30-minute readings in those 5 days. The one-day daily readings were still being recorded at that time. By January 2005, however, there was a smoother continuous record of flows consistent with the new system having been “brought on line”.

As noted above, the record of daily peak flows appeared to be trending downwards over the period 1968 to 2021. Guidance has been to not give too much credence to the actual rate of change, especially since the downward trend was not statistically significant at the 5% significance level. If the daily peaks had been better known in the years 1968 to 2004, then the downward trend might have been more pronounced, because the recorded annual peaks in the 1968-2004 would have been slightly higher, while results from 2005 would still have been as used in the analysis.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

It is noted that the gage is located to detect discharges from 10.2 square miles, or approximately two-thirds of the drainage basin contributing to the canal. An existing gage on the Makiki stream, at the South King Street bridge, and also located about 0.6 miles upstream of its own confluence with Ala Wai Canal, would ideally complement the analysis, covering much of the remaining third of the watershed, but the record from this smaller site has only 12 years of record, including a large gap from 2005 to 2011, while an unbroken 30 year record is a preferred minimum record length for statistical testing.

A summary of annual peak flow data from the shorter record is included in Figure 0.26.

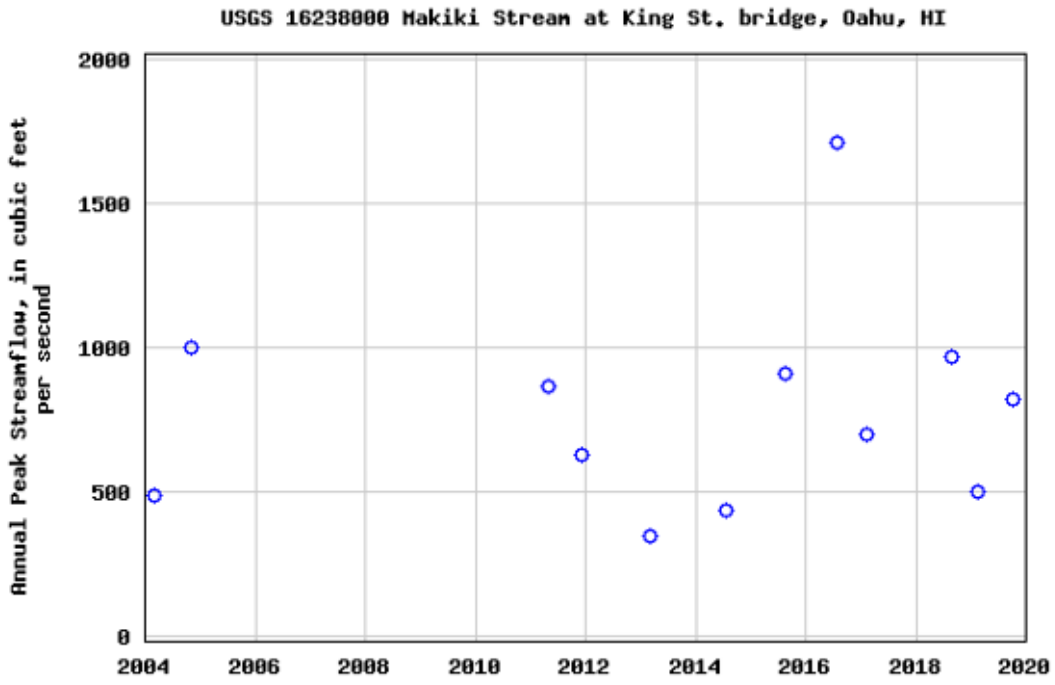

Figure 0.26 Annual Peak Discharge, Makiki Stream at King Street (USGS)

Given the small number of data points (only 12) and the relatively large gap (5 years 2006 to 2010) in the middle of the record, the Makiki Gage record has been set aside for these purposes, and the gage at the Manoa-Palolo Drain, based on a basin area of 10.2 square miles, has been taken as representative of the entire 16.2-square mile watershed with respect to trends and nonstationarities.

11. Climate Hydrology Assessment Tool

The NCA4 report indicated, based on recent projections and inferences taken from the grid network, that frequencies of drought and heavy rainfall events were likely to increase. The report acknowledged, however, that the “heavier rainfall” forecast was a recent result and not

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

supported by numerous earlier reports that projected reductions in annual average flows and annual peak flows during the 21st century.

The CHAT provides useful summary projections for most of the USA, but the coverage for Hawaii is still under development. The location of small islands smaller than a typical modeling grid cell, subject to subtle changes in prevailing wind direction, with land-elevation-based effects on atmospheric inversions and precipitation, and the cycling effects of El Niño Southern Oscillation (ENSO), all make for less straight-forward analysis.

The possibility of extending the observed record based on regression equations was investigated using the USACE Time Series Toolbox and two sets of assumptions regarding valid emission rates. These are shown in Figure 0.27 and Figure 0.28. In one case, there was a slight reduction in the mean value; in the other, there was no change in the mean value. It was noted that the software reviewed the available data to determine that by default the peak flow data set did not extend beyond 2034, an indication of its representative range. In both statistical projections, it was noted that a 97% confidence interval included projected values that were significantly smaller than zero, indicating that neither of the figures should be viewed as “true”.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

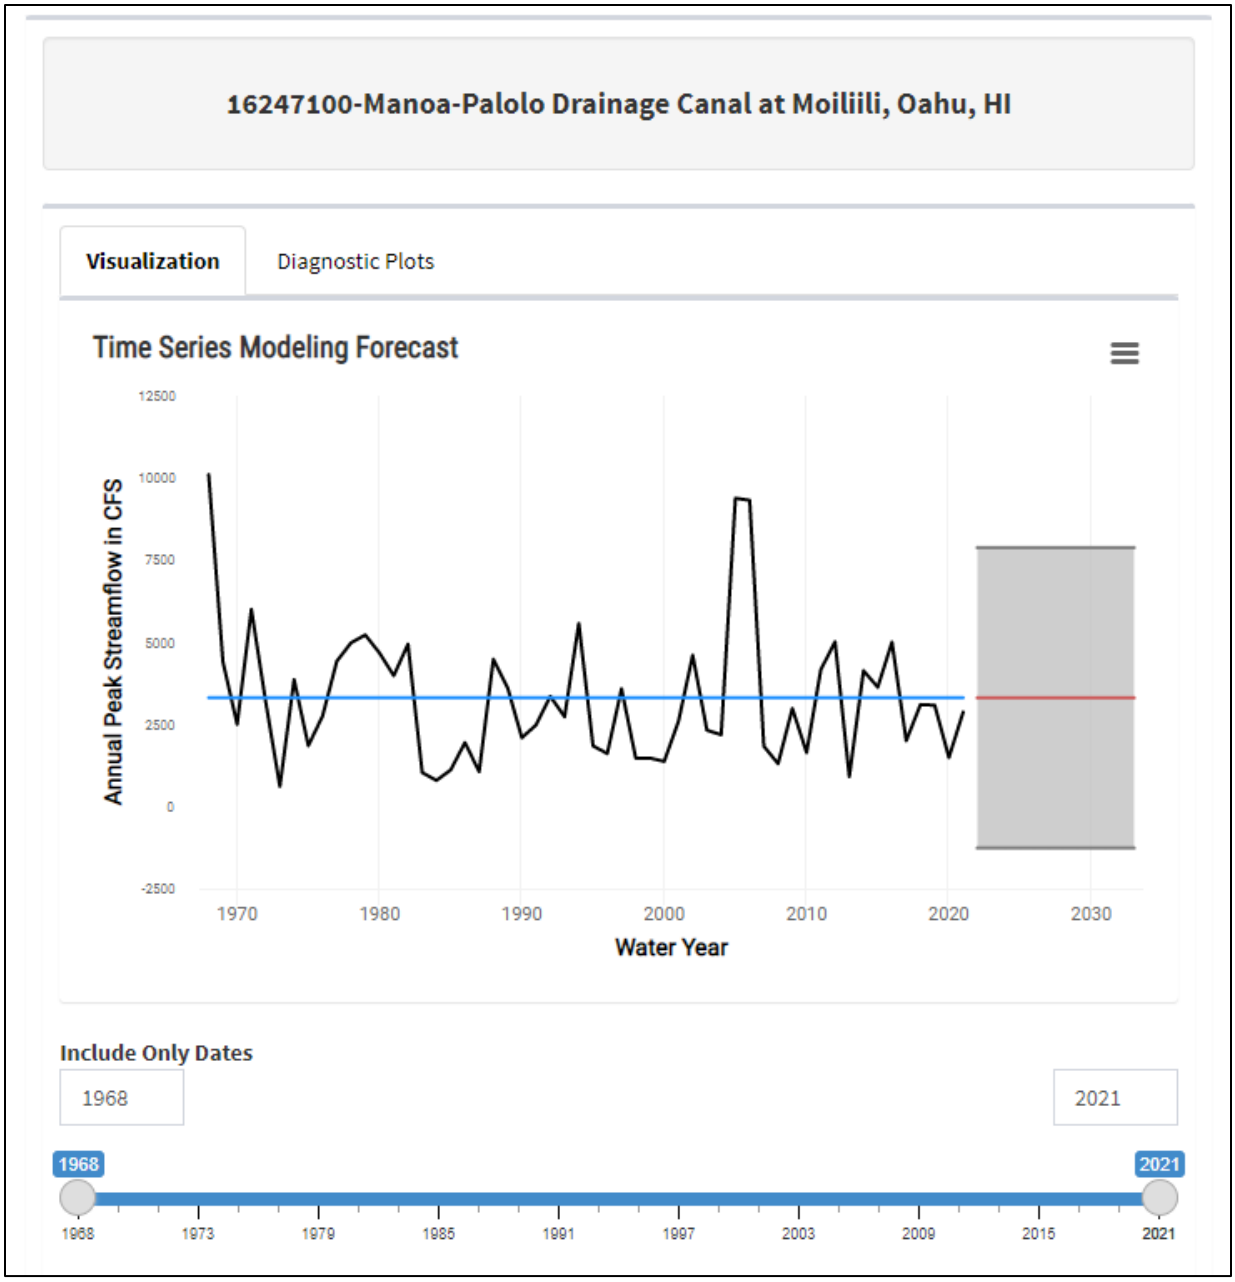

Figure 0.28 Time Series Tool Modeling Forecast (Exponential Smoothing) for the Manoa-Palolo Gage Location.

As can be seen in the figures, there are wide uncertainty bounds regarding the patterns of future annual peak flows.

12. Vulnerability Assessment

The USACE Watershed Climate Vulnerability Assessment (VA) Tool facilitates a screening-level, comparative assessment of the vulnerability of a given business line and HUC-4 watershed to the impacts of climate change, relative to the other HUC-4 watersheds within the

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

continental United States (CONUS). It uses the Coupled Model Intercomparison Project (CMIP5) GCM-BCSD-VIC dataset (2014) to define projected hydrometeorological inputs, combined with other data types, to define a series of indicator variables to define a vulnerability score.

For locations Outside the Continental US (OCONUS), however, the tool is not yet a viable method for assessing vulnerability.

Based on the literature review in this report, in the 21st century Hawaii is projected to experience increasing temperatures, decreasing average rainfall, and potentially (not all sources agree) increasing incidences of extreme storms.

1. The increasing temperatures will increase evaporation and evapotranspiration losses, reducing the amount of water available for water supply or freshwater in ecosystems.
2. The decreases in average rainfall will reduce the amount of recharge to groundwater, and for lower-lying regions, the amount of recharge from groundwater to surface water. This will result in stressed plants in the watershed, and lower flows in streams. If the plant cover is jeopardized, then bare ground will be exposed.
3. Heavy storms, falling on a dry watershed, will replenish the groundwater to some extent, although surface flow is likely to be increased more directly.
4. The increased frequency of heavy storms, falling on a stressed watershed, will lead to increased stormflows (potentially a more flashy watershed), with increased volumes of sediment and debris being washed downstream.

In this numbered/bulleted list of likely consequences, the first three are likely to reduce flooding in the Ala Wai Canal region. The fourth item, a consequence of intense downpours, would indicate that heavier stormflows should be expected on a more frequent basis.

For the State of Hawaii, Tetra Tech (2018) prepared a summary of ways to prepare for projected sea-level rise. For the Island of Oahu, their report included Figure 0.29, which included a summary of expected economic losses.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

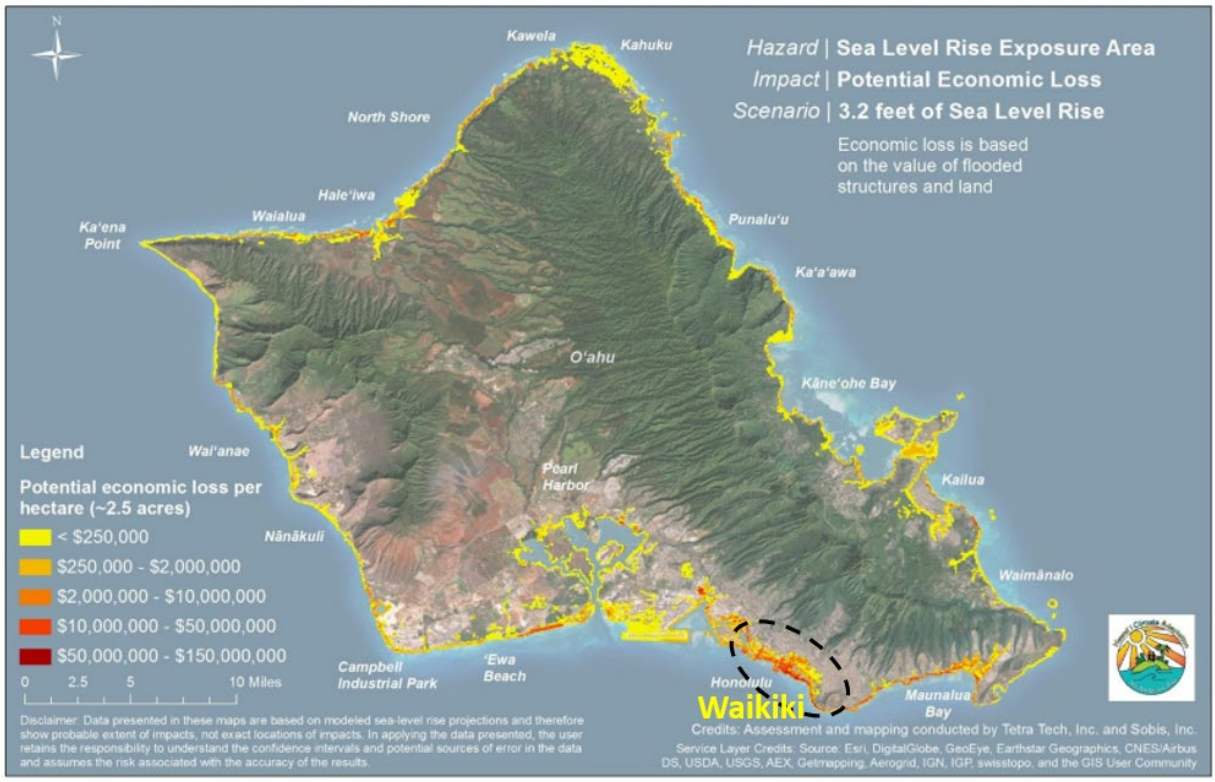

Figure 0.29 Potential Economic Loss per Hectare in Oahu due to 3.2-ft of Sea-Level Rise (Waikiki region is shown with a dashed black oval). Source: Tetra Tech (2018)

The costs (economic losses) generated in the 2018 Tetra Tech report will clearly be subject to change due to detailed developments in the region and due to annual inflation. It is noted that the Waikiki region appeared to be most vulnerable (most red part of the shading), on an island that includes the State Capital, Honolulu.

Specific to the Ala Wai watershed, the Flood Risk Management Validation Report (USACE 2021, prepared in 2017-2021) indicated a population at risk of 65,000 residents and an additional 200,000 transient visitors daily (tourists, workers, students, etc.) Modeling performed after a storm event in 2004 indicated that a one percent storm would cause damages to 3,000 structures and cause total damages of $1.14 B. The 2021 report analyzed a number of likely storm sizes and return periods, summarizing expected annual storm damage costs for without-project and with-project conditions, where more than 200 flood damage reduction measures were compared in a feasibility assessment, leading to a combination of 6 suggested renovation measures.

As of September 2023, the GRR team's real estate assessment was that 5-year to 500-year storms would cause induced damages in the range $125 M (5-year) to $5.5 B (500-year). This summary is consistent with annual induced damages in the range $100 M to $200 M per annum (actual assessment not yet available as of 9/27/2023).

Figure 0.30 shows the layout of the buildings modeled as at risk in the USACE 2021 FRM Validation Report.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

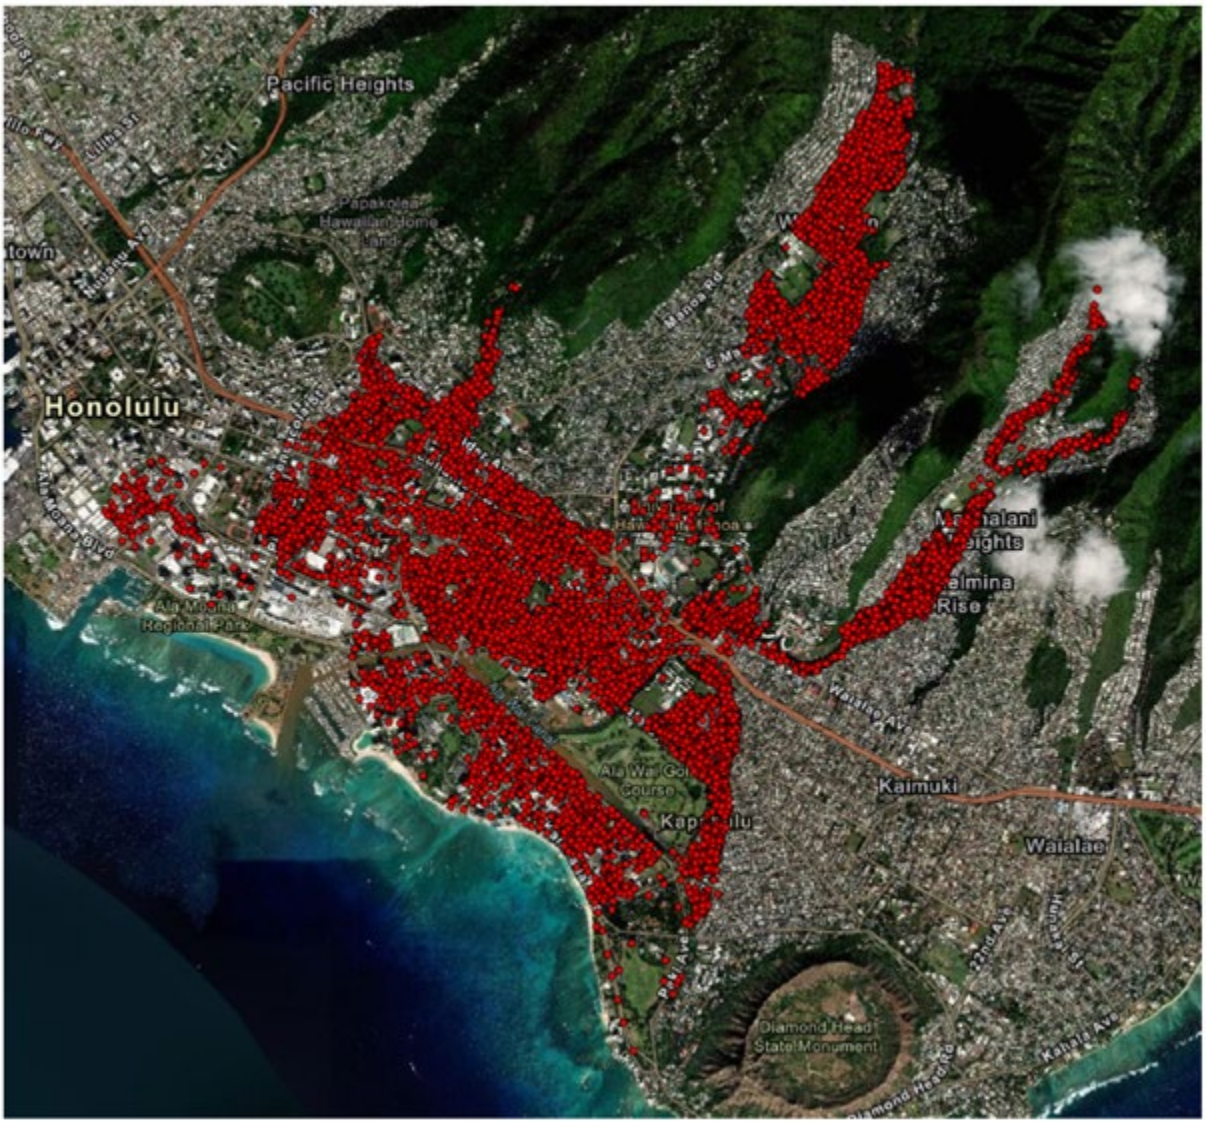

Figure 0.30 Overview of the Georeferenced Structure Inventory. Structures were taken as having entrances above ground level by 2 feet, with standard deviation 0.7 ft (uniform distribution was assumed, truncated to ignore elevations below ground level, since so few buildings actually have basements). Greater detail can be found in the USACE 2021 validation report (hydraulic and economic sections).

Figure 0.31 shows the locations of the measures proposed, including seven detention storage areas that were removed from consideration during the sensitivity review of options for the feasibility study.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Figure 0.31 USACE 2021 Summary of Project Features

Review of the inundation without, or with, the combined improvements is summarized in the two views presented in Figure 0.32. In both cases, the inundated area is mostly shown with green shading, for depths below 1 foot. Greater depths are shown in yellow (1-2 ft), red (2-3 ft), or blue (>3 ft) shading. The modeled/proposed changes led to a marked reduction in the proportion of colors representing deeper inundation.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

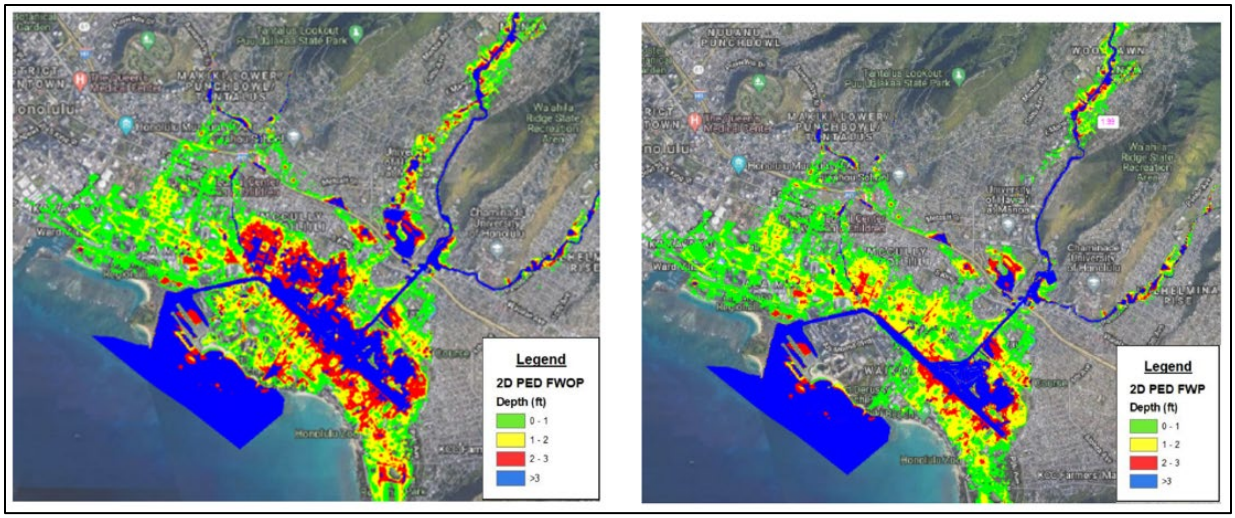

Figure 0.32 Expected AEP 0.01 (=1/100 yr) inundation for FWOP and FWP renovations, per USACE 2021 RAS model (Validation Study)

The full economic report for the case shown in Figure 0.32 (2021 FRM Validation Report) tabled eight recurrence probabilities from 0.5 to 0.002 ("2-year" to "500-year" average return-period) storms. Twenty-four damage zones were reviewed to compare damages.

In the modeled FWOP scenario, total damage costs ranged from $730,000 for the 0.5 AEP (2-year storm) case to $2,200 million for the 0.002 AEP (500-year storm) case.

In the 2021 report's With-Project scenario, total damage costs ranged from $716,000 for the 0.5 AEP case to $1,290 million for the 0.002 AEP case. The potential saving was therefore about 2% for the 2-year flood event and about 41% for the 500-year case.

The expected annual damages costs were $32.2 million for the FWOP case and $17.5 million following the report's proposed NED With-Project renovations.

The 2021 validation report indicated a need for a General Reevaluation Report (GRR) (this report) with a focus on events recurring with a more frequent average return period AEP 0.4 to AEP 0.1 (2.5-year to 10-year storms).

As part of the GRR, the 2023 TSP was developed. The layout of the TSP layout is summarized in Figure 0.33.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

13. Conclusion

Recent climate science literature indicates observed trends of rising mean and extreme temperatures. The literature indicates that the observed annual mean precipitation is reducing over time, with ambiguous projections regarding annual maximum values. These trends are less easy to extract from the data due to changes in the cyclical patterns of the El Niño Southern Oscillation (both severity and periodicity). Prevailing wind directions appear to be shifting over time; and the extent of any changes to the interplay between low-level and upper-level wind, with their varying temperatures and percent saturation, remain uncertain.

The literature is ambiguous on projected stream runoff trends.

As a result, regional projections of future streamflows are mixed and depend on the climate model and its assumptions.

In lieu of a climate-model projection method, the Time Series Tool was used to extend the existing observation record for the site to the year 2034, but the short extension had such wide uncertainty bands on the resulting “projections” that no clear pattern emerged.

The nonstationarity analysis did not indicate the presence of any strong nonstationarities in the record of annual peak inflows to the canal system. Trend analysis of observed 3-day peak inflow data showed a slight decreasing trend, but this was not statistically significant.

The watershed (Makiki, Manoa and Palolo Streams, discharging to the Ala Wai Canal, which discharges to the Pacific Ocean) is known to be vulnerable in the flood risk management business line. No comparison has been made between this risk, or the potential future risk, and vulnerabilities in other USACE districts.

The project is intended for riverine flooding reduction, although there are significant sea-level components to the downstream boundary conditions of the associated hydraulic modeling.

Sea level rise is a clear issue for Oahu, and particularly for the Waikiki area of interest in this study. The TSP has been evaluated using hydraulic modeling of FWP and FWOP assumptions, based on the USACE intermediate sea-level-rise assumptions through 2080. A sensitivity analysis indicated that the TSP likely provides significant reduction in inundation, for storms up to the 20-year event, through at least 2100, even under the USACE high SLC assumptions.

As indicated in **Table 0.5**, high runoff events caused by more runoff in general or more intense storms would lead to more damaging effects in the study area. The analysis of flows at the site, however, does not lead to a conclusion of increases in either average or peak flows over time. Regionally, average flows appear to be diminishing over time, but peak flows may be rising relative to the average flows. It is not clear whether the damaging high flows would be increased or diminished over time. The table outlines how the main risk management measures considered in the study might be affected by changes in inflow patterns. Since the regional and site-specific data do not indicate a clear climatic change underway for the basin with respect to peak riverine flows, it is unclear how the climate trends that have been examined would affect the measures under consideration. The residual flood risk to the project, due to climate change, is therefore classified as low.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Based on this assessment, the recommendation is to treat the potential effects of climate change and long-term natural variability in climate as occurring within the uncertainty range calculated for the current hydrologic analysis.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Table 0.5 Residual Risk to Ala Wai Canal Due to Climate Change

Residual Risk to Ala Wai Canal Due to Climate Change

Feature or Measure	Trigger	Hazard	Harm	Qualitative Likelihood
Approved/designed combination of features/ measures is installed: • tunnels, • channel bypass, • channel modifications, • daylighting, • detention, • channel naturalization, • grade control structures, • underground storage, • bridge modifications, • floodwalls, • submerged pipes, • microtunnels, • debris management/ catchments, • canal deepening/ widening, • vertical storage tunnels.	Higher precipitation and temperatures result in more extreme runoff events.	FWOP per 2021 estimates: PAR is large: 65,000 residents and 200,000 daily visitors (mostly tourists). 17,085 structural features: homes, residential vehicles, businesses, public structures, street segments. Flood damages as $721 million for an AEP 1/100 y storm; or $2.20 B for AEP 1/500 y storm.	Widespread flooding between 1 and 3 feet deep (approximately 6 square miles). Assessment of loss of life not located. **Annual damages assessed in 2021:** **FWOP $32.2 million.** ***(2021 FRM Validation Report; report noted that FDA indicated essentially a doubling of the one-time damages for increases from a 1/50 yr to 1/100 yr, and again from 1/100 yr to 1/200 yr cases.)*** **With-Project: $17.5 million.** [Preliminary: GRR September 2023 assessed storm-induced damages of: $125 M (5-yr) or $5.5 B (500-year): consistent with annual induced damages in the range $100 M to $200 M per annum (actual assessment not yet available as of 9/27/2023).]	**Low probability** of increased flooding due to climate change. It is not clear whether, due to climate change, there will be an increase or decrease in annual peak flows. **USACE (2015)** indicates this uncertainty; **NCA4** acknowledges the uncertainty but points to likely increases in peak flow despite decreases in average flow. **Site-specific data** review shows a slight drop in annual peak streamflow. "**Low**" assessment is taken as valid for all measures.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Residual Risk to Ala Wai Canal Due to Climate Change

Feature or Measure	Trigger	Hazard	Harm	Qualitative Likelihood
Details as shown above.	Sea-level rises closer to the USACE high-curve projection than the assumed intermediate-curve projection.	Project design condition is reached in 2040 to 2045 (not 2080).	Damages are approximately as developed in 2021. System failure: up to 2.2 feet of inundation more than estimated in the vulnerable area. The change in the inundation level is limited to the immediate vicinity of the canals, for unusually large storms (greater than the 20-year event). [Preliminary: GRR September 2023 assessed storm-induced damages of: $125 M (5-yr) or $5.5 B (500-year): consistent with annual induced damages in the range $100 M to $200 M per annum (actual assessment not yet available as of 9/27/2023).]	**Low**: the monitored data appears to be tracking the intermediate curve. Hydraulic sensitivity modeling indicates that, with the high RSLC assumption, the TSP system is effective for at least the assumed 20-year flood, at least to the year 2100.

The purpose of this study is flood risk management. The recent literature points to smaller average flows over time but is not clear about whether the runoff associated with stormflows will be greater or smaller as a result. Site-specific data indicates a slight reduction in annual peak flows, but there are large uncertainty bounds associated with this extrapolation which extended by default only as far as 2034. The potential for change in the high-flow runoff patterns may become apparent with the collection of more years of runoff data and/or further climate modeling.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

US Army Corps of Engineers

General Reevaluation Report with Integrated Supplemental Environmental Impact Statement

Appendix I — Real Estate

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

This document contains CONTROLLED UNCLASSIFIED INFORMATION (CUI). It contains information that may be exempt from public release under the Freedom of Information Act (5 USC 552). It is to be controlled, stored, handled, transmitted, distributed, and disposed of in accordance with USACE policy relating to CUI information and it is not to be released to the public or other personnel who do not have a valid “need to know” without prior written approval of an authorized USACE official.

Report Status: Draft, November 2023

EXECUTIVE SUMMARY

The Ala Wai General Reevaluation Report (Study) with Integrated Supplemental Environmental Impact Statement is authorized under Section 209 of the Flood Control Act of 1962 (Public Law 87-874) and Section 216 of the Flood Control Act of 1970, as amended. The Real Estate Plan (REP) is generally prepared as an appendix to the Study to support the acquisition requirements of the TSP. The REP presents the real estate requirements, proposes the acquisition strategy, develops a cost estimate for real estate acquisition, and incorporates an internal technical review.

A Tentatively Selected Plan (TSP) was selected based on cost, ecological output, economic benefits, completeness, effectiveness, efficiency, and acceptability. The TSP includes constructing one detention basin (Ala Wai Golf Course Detention Basin: 128.35 ac.), one levee (Ala Wai Golf Course Levee, Inlet Culvert, Outlet Culvert: 9.18 ac.), and three floodwalls (Ala Wai Canal Floodwall: 3.83 ac., Koali Road Floodwall: 0.70 ac., and Woodlawn Bridge Floodwall: 0.35 ac.). Relocation of utility easements totaling 3.35 acres is anticipated. Construction areas and access routes are estimated alongside project features. Additionally, four staging areas estimated at 5.56 acres are planned in close proximity to the project features. Construction is anticipated for two (2) years.

The Non-Federal Sponsor (NFS) for the Study is the City and County of Honolulu (CCH). The NFS is responsible for ensuring that it possesses the appropriate real estate interests for all real property required for the proposed project. The minimum estate required for the detention basin is a permanent flowage easement totaling 128.35 acres. The minimum estate required for the floodwalls are flood protection levee easements totaling 14.06 acres. The minimum estate required for staging, construction, and site access are temporary work area easements totaling 5.54 acres. The minimum estate required for utility relocations is utility easements totaling 3.35 acres.

Both residential and commercial structures are anticipated to be affected by the placement of structural project features. Five commercial and residential structures are anticipated to be relocated due to the Woodlawn Bridge Floodwall, Koali Road Floodwall, and Ala Wai Canal Floodwall. Relocation values including relocation benefits are estimated at $5,299,900.

Induced flooding is reasonably anticipated as a result of the Ala Wai Golf Course Detention Basin, Ala Wai Golf Course Floodwall, Koali Road Floodwall, and Woodlawn Bridge Floodwall. Due to the significant induced flooding estimated to cover the entirety of the detention basin, a permanent flowage easement is required. Additionally, induced flooding is also anticipated as a result of the proposed floodwalls. Further legal analysis is required on a parcel-by-parcel basis regarding physical invasion takings and just compensation payment requirements. Due to recent Federal Circuit legal opinions, a conservative range of estimated buyouts is assumed, which indicates a fee simple value ranging from $124.55M (5yr event, 2 parcels affected) to $5.47B (500yr event, 673 parcels affected).

The estimated real estate cost associated with the TSP is approximately $58,088,600, including all recommended lands, easements, rights-of-way, relocations, and disposals (LERRDs), relocations, incremental real estate contingency, administrative costs to be carried out by the NFS, and Government costs for LERRDs monitoring and certification. The real estate cost estimate above does not include estimated costs for induced flooding, which may range from $124.55M to $5.47B. The NFS will be assessed on its capability to acquire and provide the LERRDs necessary for the proposed project.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

1. Authority and Purpose

The Study is authorized under Section 209 of the Flood Control Act of 1962 (Public Law 87-874) and Section 216 of the Flood Control Act of 1970, as amended. A Feasibility Cost Share Agreement (FCSA) was executed between USACE and the non-Federal sponsor, CCH Engineering Division, in 2001.

The U.S. Army Corps of Engineers (USACE), in partnership with the CCH, is identifying and assessing flood risk management alternatives. This study was appropriated under the Supplemental Appropriations of the Bipartisan Budget Act of 2018 (Public Law 115-123), dated 9 February 2018, which funded the initiation and completion of previously authorized flood and storm damage reduction studies.

Past studies include a Reconnaissance Report (1999), Ala Wai Flood Study (2001), and Manoa Watershed Study (2006). The Reconnaissance Report sought a comprehensive management and restoration plan to restore aquatic habitat and biological diversity in the Canal and upstream tributaries. The Ala Wai Flood Study identified several mitigative measures and conceptual alternatives that could potentially minimize flood damages to Waikiki and the surrounding area. The results of this technical study were used to establish that the USACE could be involved in the investigation of flood risk management in the Ala Wai Canal. The Mānoa Watershed Project resulted in detailed topographic mapping, hydrologic and hydraulic modeling, and identification of potential measures to address specific flood problems; however, it was terminated before implementation. Information developed through the Mānoa Watershed Project by NRCS was subsequently incorporated into the Ala Wai Canal Project, which was restarted in 2007.

Due to the potential for unavoidable, significant effects an Environmental Impact Statement was prepared for compliance with the National Environmental Policy Act (NEPA). Environmental analysis will comply with all environmental laws as applicable. The analysis is anticipated to be completed by relying on existing literature, remote sensing technologies, and data available from other agencies for use in GIS.

Generally, the Real Estate Plan (REP) is prepared by the USACE Honolulu District (District) as an appendix to the Feasibility Report. The REP presents the real estate requirements, proposes the acquisition strategy, develops a cost estimate for real estate acquisition, and incorporates an internal technical review. USACE Mapping reviews tract ownerships and acreages to prepare exhibits for the REP. USACE Appraisal prepares (or contracts for) and approves a cost estimate or gross appraisal, as needed for acquisitions. USACE Environmental provides applicable compliance memoranda and/or documentation in accordance with NEPA/Hawaii Environmental Policy Act (HEPA), National Historic Preservation Act (NHPA), and USACE Hazardous, Toxic, and Radioactive Waste (HTRW) policy.

Project real estate requirements include a review of NFS-owned parcels as well as required LERRDs to be carried out by the NFS. LERRDs are requirements that the U.S. Government has determined the NFS must meet for the construction, operation, and maintenance of the project. If LERRDs are required, USACE Real Estate coordinates with the NFS and provides the NFS with a partner packet outlining the NFS's responsibilities and notice informing the NFS of the risks of early acquisition.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

The information contained herein is tentative for planning purposes only. Final real property acquisition acreages, limitations, and cost estimates are subject to change after approval of a final Feasibility Report, including plan modifications that occur during the Preconstruction Engineering and Design Phase (PED).

2. Project Description and Location

The Ala Wai Watershed is located on the southeastern side of the island of Oahu, Hawai'i, and includes Makiki, Mānoa, and Palolo streams, all of which drain to the Ala Wai Canal. The watershed encompasses 19 square miles (12,064 acres) and extends from the ridge of the Ko'olau Mountains to the nearshore waters of Mamala Bay. The Canal is a 2-mile-long waterway constructed during the 1920s to drain extensive coastal wetlands, thus allowing development of the Waikiki District. A large portion of the watershed, including most of Waikiki, is highly susceptible to flooding. See Figure 2-1: Study Area.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Figure 2-1: Study Area

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

A high level of flood risk exists within the Ala Wai Watershed. Extensive urban development throughout the watershed, coupled with the basin's unique topography and hydrology (i.e., steep mountainous terrain and propensity for intense rainfall events within the headwaters) and aging and undersized infrastructure result in elevated flood risk for a large proportion of the population both along the Ala Wai Canal and within the Makiki, Mānoa, and Palolo valleys. To combat flooding, a final array of alternative plans was formulated through combinations of screened management measures. Final Study alternatives included:

- Alternative 0: No Action
- Alternative 1: Storage Cornerstone
- Alternative 2B: Conveyance Cornerstone
- Alternative 5.3: Hybrid

2.1. Tentatively Selected Plan: Hybrid

Alternative 5.3: Hybrid was selected as the Tentatively Selected Plan (TSP). Project features, also referred to as measures, include:

1. Ala Wai Golf Course Detention Basin: 128.35 ac.
2. Ala Wai Golf Course Levee, Inlet Culvert, Outlet Culvert: 9.18 ac.
3. Ala Wai Canal Floodwall: 3.83 ac.
4. Koali Road Floodwall: 0.70 ac.
5. Woodlawn Bridge Floodwall: 0.35 ac.
6. Construction and Staging Areas: 5.54 ac.
7. Utility Relocations: 3.35 ac.

Ala Wai Golf Course Detention Basin and Levee – At Ala Wai Golf Course, adjacent to the Manoa-Palolo Canal and the Ala Wai Canal, an earthen levee approximately 6-9 ft in height would be constructed around the perimeter of Ala Wai Golf Course to create a detention basin (i.e., Ala Wai Golf Course Detention Basin). The total length of the earthen levee would be approximately 8,315 ft in length and would extend along the perimeter of the Ala Wai Golf Course along the Manoa-Palolo and Ala Wai canals. On the left descending bank of the Manoa-Palolo Canal, there is an overtopping spillway section, approximately 100 feet in length, that is reinforced with erosion protection. The levee along the Manoa-Palolo Canal is also lined with erosion protection on the canal side. A portion of the existing drainage ditch that runs along the north side of the golf course (parallel to Date Street) would be used as an inlet location for overflow into the Ala Wai Golf Course Detention Basin. A small inlet channel would be excavated and lined with erosion control material to improve the flow onto the golf course. Three concrete drainage structures and three flap gates would be constructed along the levee alignment of the Ala Wai Golf Course to allow collected stormwater within the basin and from local runoff to slowly drain into Ala Wai Canal. The detention basin also includes a floodwall along the golf course parking lot near the Ala Wai Canal, which is 9 feet in height. The floodwall has one concrete drainage structure and two flap gates. The drainage structure at this location

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

serves to outlet flow from the Diamond Head neighborhood. The original outlet will be enclosed by concrete (instead of daylighted) and will need reconstruction of the vehicle and pedestrian access at this location. A small section of floodwall near the Kapahulu Avenue and Ala Wai Boulevard intersection at the Diamond Head end of the canal will tie-in to the golf course levee and Ala Wai Canal floodwall system. This section is 6 feet in height and includes one road closure structure and one drainage structure. Finally, there is one canoe access point in this location. The Ala Wai Golf Course Detention Basin would reduce the risk of flooding within the lower watershed.

Ala Wai Canal Floodwall – At the Manoa-Palolo Canal and Ala Wai Canal, a floodwall extending 6 ft above ground (i.e., Ala Wai Canal Floodwall) would be constructed. The floodwall would be approximately 22,852 ft long. Existing stormwater sewers inletting into the Ala Wai Canal would be modified so that fourteen would be drainage structures and 59 would be retrofitted with flap gates. Eleven road closure structures would be constructed. There are three canoe access points for this feature. The typical cross section of this feature varies along the alignment but all are assumed to be 6 feet above ground. The floodwall along the Ala Wai Canal and the lower right descending bank of the Manoa-Palolo Canal will include an elevated walking path. On the left descending bank of the Manoa-Palolo Canal and near Kaimuki High School, there will be a floodwall on micropiles with no walking path. Where space is constricted, along the upper right descending bank of the Manoa-Palolo Canal, Giken walls (tied-back I-wall) will be constructed, with no walking path. The purpose of the Ala Wai Canal Floodwall system would be to reduce the risk of flooding within the McCully-Moiliili neighborhood, Diamond Head neighborhood, and Waikiki.

Woodlawn Drive Floodwall & Koali Road Floodwall – Also within Manoa Valley, a floodwall extending 6 ft above ground level (i.e., Woodlawn Drive Floodwall) would be constructed along the right descending bank of Manoa Stream. The floodwall would be approximately 1,270 ft in length. A single road closure structure at Woodlawn Drive would be constructed. The Woodlawn Drive Floodwall would reduce the risk of flooding to the University of Hawaii and downstream residential structures due to overtopping at Woodlawn Drive Bridge. At Koali Road, near the convergence of Manoa and Palolo streams, a floodwall extending 6 ft above ground (i.e., Koali Road floodwall) would be constructed along the left descending bank of Manoa Stream and the right descending bank of Palolo Stream. The floodwall would be approximately 2,510 ft in length. Two concrete drainage structures would be constructed to provide interior drainage of stormwater flows from the residential neighborhood behind the Koali Road floodwall. Two flap gates would be retrofitted on smaller stormwater culverts along this feature. Two road closure structures would be constructed. The purpose of the Koali Road Floodwall is to reduce risk to adjacent residential structures, including induced damages caused by the Woodlawn Drive Floodwall. Thus, the Woodlawn Drive Floodwall and Koali Road Floodwall function as a system.

Construction areas have been identified adjacent to project features. Additionally, four staging areas have been identified for the storage of materials and equipment. The staging areas would be restored upon construction completion. Construction is anticipated for two (2) years.

The TSP includes life-cycle maintenance with operation, maintenance, repair, replacement, and rehabilitation (OMRR&R) performed on a routine basis. The NFS is aware of its responsibility to perform all OMRR&R. A detailed OMRR&R plan will be prepared during the detailed design phase. See Figure 2-2: Project Feature Map 1, Figure 2-3: Project Feature Map 2, Figure 2-4: Project Feature Map 3, and Figure 2-5: Project Feature Map 4.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

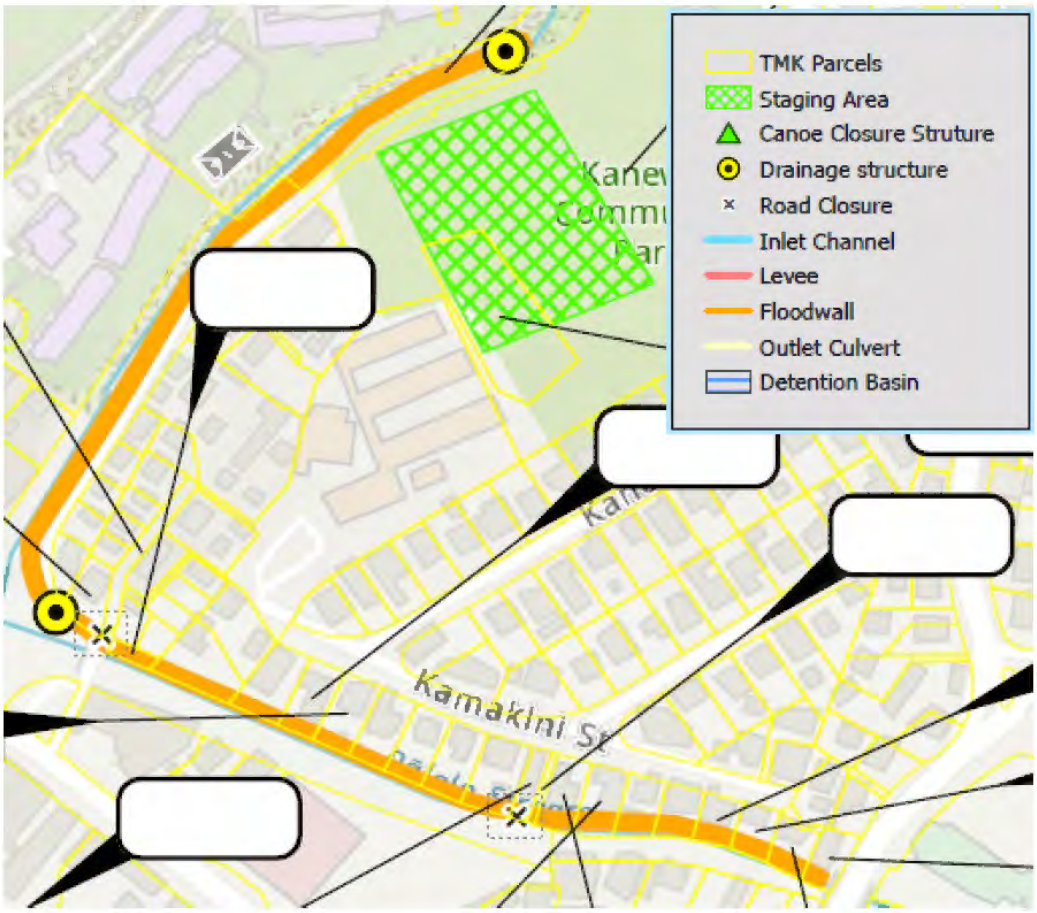

Figure 2-4: Project Feature Map 3

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

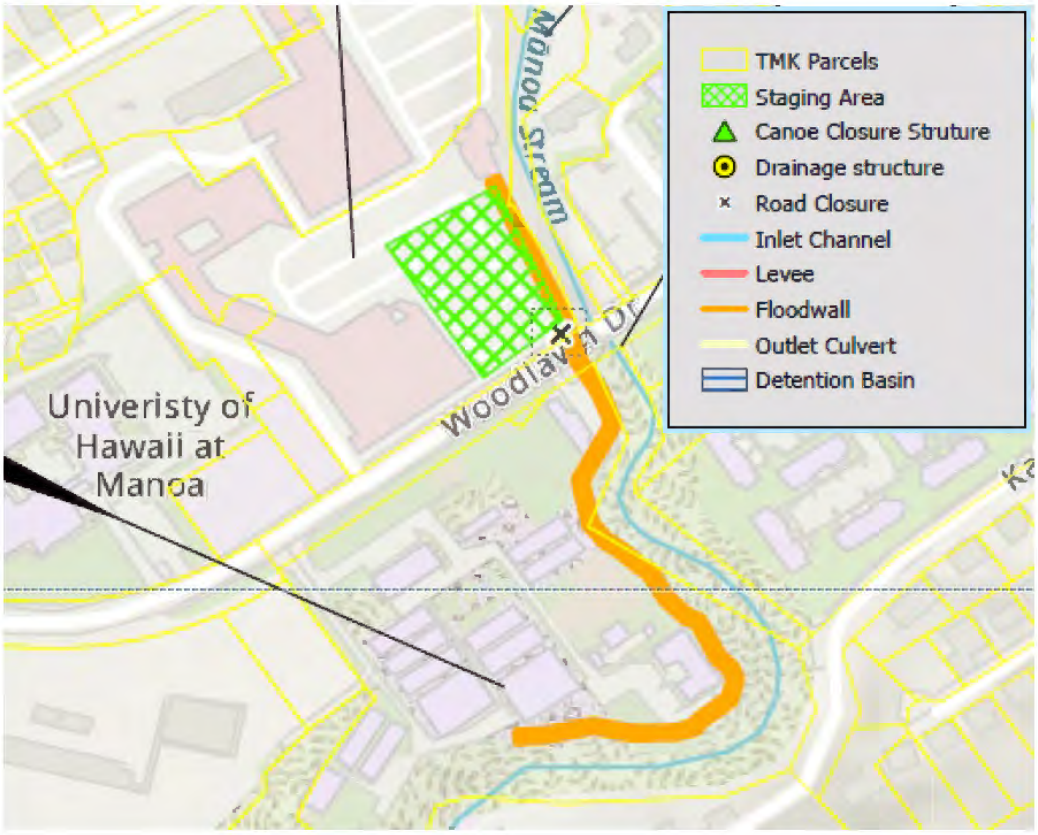

Figure 2-5: Project Feature Map 4

2.2. Structures in the Area

The project footprint encompasses the physical location of the TSP and all included project features or measures, either individually or collectively, that will be impacted to facilitate construction associated with the TSP The project footprint includes numerous public and private structures, facilities, and utilities. The Civil Engineering Appendix indicates that proposed project features are anticipated to affect existing structures. See Section 10: Facility and Utility Relocations for further information.

2.3. Staging and Construction

Four staging areas totaling approximately 5.54 acres have been identified. Staging areas include: Ala Wai Golf Course Staging Area (2.29 ac.), Koali Road Floodwall Staging Area 1 (0.43 ac.), Koali Road Floodwall Staging Area 2 (1.82 ac.), and Woodlawn Bridge Floodwall Staging Area (0.99 ac.). Staging areas and site access must be established for the use and distribution of construction materials and equipment. The staging area generally contains contractor trailers, parking, fencing, and storage of equipment and materials. Additionally, construction is assumed within a 10-foot-wide corridor alongside the structural project features, See Figures 2-2 to 2-5 above for staging area locations. Staging and construction will be required for two (2) years during project construction.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

2.4. Site Access

It is anticipated that personnel, equipment, and imported materials would access project construction along public roadways parallel to the airport. Access points identified within the public roadways can be used without additional perpetual real estate interests for operations and maintenance. Access routes have not yet been identified by the civil engineering report. If additional real estate interests are required for access points identified adjoining construction areas outside of public roadways, they will be included in temporary work area easements as project features are refined.

2.5. Ownership by Project Feature

The following Table 2-1: Real Estate Interest Required by Project Feature summarizes the land areas and real estate interests by project feature.

Table 2-1: Real Estate Interest Required by Project Feature

Project Feature	Approximate Area (Acres)	Owner	Zoning	Interest Required
1. Ala Wai Golf Course Detention Basin	128.35	State	Preservation	Flowage Easement (permanent)

3. Sponsor's Real Estate Interests

Based on a review of the City & County of Honolulu Department of Planning & Permitting maps, it is assumed that the NFS owns some interests required for proposed project feature (DPP, 2023).

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

4. Estates Required

The NFS is responsible for providing all LERRDs required for the construction, operation, and maintenance of the project. The NFS is instructed to acquire the minimum real estate interests necessary for the project. LERRDs required for the proposed project include:

4.1. Flowage Easement (permanent)

1. Ala Wai Golf Course Detention Basin: 128.35 acres

The minimum estate required for the detention basins is a permanent flowage easement totaling approximately 128.35 acres.

Flowage Easement (Permanent)

The perpetual right, power, privilege and easement permanently to overflow, flood and submerge (the land described in Schedule A) Tracts Nos. _____, _____ and _____), (and to maintain mosquito control) in connection with the operation maintenance of the project as authorized by the Act of Congress approved _____, and the continuing right to clear and remove and brush, debris and natural obstructions which, in the opinion of the representative of the United States in charge of the project, may be detrimental to the project, together with all right, title and interest in and to the timber, structures and improvements situate on the land (excepting _____, (here identify those structures not designed for human habitation which the District Engineer determines may remain on the land)); provided that no structures for human habitation shall be constructed or maintained on the land, that no other structures shall be constructed or maintained on the land except as may be approved in writing by the representative of the United States in charge of the project, and that no excavation shall be conducted and no landfill placed on the land without such approval as to the location and method of excavation and/or placement of. landfill; the above estate is taken subject to existing easements for public roads and highways, public utilities, railroads and pipelines; reserving, however, to the landowners, their heirs and assigns, all such rights and privileges as may be used and enjoyed without interfering with the use of the project for the purposes authorized by Congress or abridging the rights and easement hereby acquired; provided further that any use of the land shall be subject to Federal and State laws with respect to pollution.

4.2. Flood Protection Levee Easement

2. Ala Wai Golf Course Levee: 9.18 acres
3. Ala Wai Golf Course Floodwall: 3.83 acres
4. Koali Road Floodwall: 0.70 acres
5. Woodlawn Bridge Floodwall: 0.35 acres

The minimum estate required for the floodwalls is a perpetual flood protection levee easement totaling approximately 14.06 acres.

Flood Protection Levee Easement Standard Estate

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

A perpetual and assignable right and easement in (the land described in Schedule A) (Tracts Nos, _____, _____ and _____) to construct, maintain, repair, operate, patrol, and replace a flood protection (levee) (floodwall)(gate closure) (sandbag closure), including all appurtenances thereto; reserving, however, to the owners, their heirs and assigns, all such rights and privileges in the land as may be used without interfering with or abridging the rights and easement hereby acquired; subject, however, to existing easements for public roads and highways, public utilities, railroads, and pipelines.

4.3. Temporary Work Area Easement

6. Construction and Staging Areas: 5.54 acres

The minimum estate required for construction and staging, including access, is a temporary work area easement totaling approximately 5.54 acres. The temporary work area easement is estimated to be required for two (2) years during project construction.

Temporary Work Area Easement Standard Estate

A temporary easement and right of way in, on, over and across (the land described in Schedule A) (Tracts Nos. _____, _____ and _____), for a period not to exceed _____, beginning with date of possession the land is granted to the United States, for use by the United States, its representatives, agents, and contractors as a (borrow area) (work area), including the right to (borrow and/or deposit fill, spoil and waste material thereon) (move, store and remove equipment and supplies, and erect and remove temporary structures on the land and to perform any other work necessary and incident to the construction of the Project, together with the right to trim, cut, fell and remove therefrom all trees, underbrush, obstructions, and any other vegetation, structures, or obstacles within the limits of the right of way; reserving, however, to the landowners, their heirs and assigns, all such rights and privileges as may be used without interfering with or abridging the rights and easement hereby acquired; subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

4.4. Utility Easement

10. Utility Relocations: 3.35 acres

The minimum estate required for relocation of existing sewer, water, gas, and power utilities along the Koali Road Floodwall, Ala Wai Golf Course Detention Basin, and the Ala Wai Canal Floodwall is a utility easement totaling approximately 3.35 acres. The size of the utility easement is assumed as a 20-foot wide easement.

Utility and/or Pipeline Easement Standard Estate

A perpetual and assignable easement and right of way in, on, over and across (the land described in Schedule A) (Tracts Nos. _____,_____ and _____), for the location, construction, operation, maintenance, alteration; repair and patrol of (overhead) (underground) (specifically name type of utility or pipeline); together with the right to trim, cut, fell and remove therefrom all trees, underbrush, obstructions and other vegetation, structures, or obstacles within the limits of the right-of-way; reserving, however, to the landowners, their heirs and assigns, all such rights and privileges as may be used without interfering with or abridging the rights and easement

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

hereby acquired; subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

5. Federal Projects/Ownership

There are no current proposed project features with prior Federal project credit. Additionally, there are no Federally owned lands within the LERRDs required for the proposed project. Any interest in land provided as an item of local cooperation for a previous Federal project is not eligible for credit.

6. Navigation Servitude

As the Study does not propose any features with waterways, navigation servitude is not applicable to this Study. The navigation servitude is the dominant right of the Government under the Commerce Clause of the U.S. Constitution (U.S. CONST. art.I, §8, cl.3) to use, control, and regulate the navigable waters of the United States and the submerged lands thereunder for various commerce-related purposes including navigation and flood control. In tidal areas, the servitude extends to all lands below the mean high-water mark. In non-tidal areas, the servitude extends to all lands within the bed and banks of a navigable stream that lie below the ordinary high-water mark.

Generally, it is the policy of the USACE to utilize the navigation servitude in all available situations, whether or not the project is cost-shared or fully Federally funded. Lands over which the navigation servitude is exercised are not to be acquired nor eligible for credit for a Federal navigation or flood control project or another project to which a navigation nexus can be shown.

7. Maps

Maps are intended as a preliminary tool to illustrate the project footprint, LERRDs to be acquired, and lands within the navigation servitude. Changes to LERRDs footprints may occur and cost estimates are subject to change even after approval of the Integrated Feasibility Report, including plan modifications that occur during the PED phase. Detailed maps will be provided prior to the Notice to Acquire (NTA), which is the formal notification to the NFS of the required LERRDs. For the purposes of this study, including Study location and Study area, refer to Figure 2-1: Study Area. For LERRDs requirements, refer to Figure 2-2: Project Feature Map 1 through Figure 2-5: Project Feature Map 4.

8. Induced Flooding

Induced flooding is reasonably anticipated as a result of the following project features: Ala Wai Golf Course Detention Basin, Ala Wai Golf Course Floodwall, Koali Road Floodwall, and Woodlawn Bridge Floodwall. Where significant induced flooding is anticipated, or where otherwise required, a written legal analysis is performed incorporating facts relating to the depth, frequency, duration, and extent.

The Ala Wai Golf Course Detention Basin hydrologic and hydraulic models indicate that storm water is anticipated to be drained within 45 minutes of a flood event, but that it could take up to

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

three days for all water to drain. As significant induced flooding is anticipated for flood events, covering the entirety of the detention basins, a permanent flowage easement is required.

Induced flooding is also anticipated in nearby properties as a result of structural project features. A preliminary assessment was conducted utilizing Induced Flooding by Reach prepared by USACE NWO, August 21, 2023. Further legal analysis is required on a parcel-by-parcel basis regarding physical invasion takings and just compensation payment requirements. Due to recent Federal Circuit legal opinions, a conservative approach to estimated buyouts required due to takings is assumed. Table 8-1 below illustrates the number of parcels and the estimated value of those affected parcels by flood event. As illustrated, even at the 5-year flood event affecting two parcels, the fee simple value is $124.55M. By the 500-year event, 673 parcels affected are estimated at $5.47B.

Table 8-1: Induced Flooding Buyout Estimate by Flood Event

Flood Event	Number of Parcels Affected	Value of Affected Parcels
5Yr	2	$124,551,000
10Yr	7	$143,417,000
20Yr	16	$238,667,000
50Yr	57	$1,153,860,000
100Yr	76	$2,488,618,000
200Yr	85	$3,047,232,000
500Yr	673	$5,466,734,000

9. Baseline Cost Estimate for Real Estate

The estimated real estate cost associated with the TSP is approximately $58,088,600, which includes required interests, relocations, incremental real estate contingency, and incidental acquisition costs for both the NFS and Government.

Table 9-1: Baseline Cost Estimate for Real Estate

Real Estate Requirement	Size (Acres)	Cost Estimate
1. Ala Wai Golf Course Detention Basin: Flowage Easement (permanent)	128.35	$8,691,500
2. Ala Wai Golf Course Levee: Flood Protection Levee Easement	9.18	$5,398,100
3. Ala Wai Canal Floodwall: Flood Protection Levee Easement	3.83	$17,413,800
4. Koali Road Floodwall: Flood Protection Levee Easement	0.70	$4,673,900
5. Woodlawn Bridge Floodwall: Flood Protection Levee Easement	0.35	$2,387,100
6. Staging and Construction: Temporary Work Area Easement	5.54	$4,731,700
7. Utility Relocations	3.35	$2,810,500
8. Residential/Commercial Relocations	0.21	$5,249,900

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Hazard Removals	$0
Mineral Rights	$0
Damages	$0
Uniform Relocation Assistance	$50,000
Incremental Real Estate Costs (Contingency)	$6,494,400
Incidental Acquisition Costs: NFS	$157,600
Incidental Acquisition Costs: Government	$30,100
TOTAL	**$58,088,600**

The values for the baseline cost estimate were obtained from a Land Cost Estimate Report prepared by a licensed USACE appraiser, Northwestern Division, effective June 8, 2023. In accordance with USACE Real Estate Policy Guidance Letter 31, Real Estate Support to Civil Works Planning, a cost estimate is sufficient for projects in which the value of LERRDs is not expected to exceed 15 percent of total project costs. A cost estimate is not an appraisal as defined by the Uniform Standards Professional Appraisal Practice (USPAP); however, it conforms to USACE regulations. Cost is an estimate of fact, not an opinion of value, based upon land planning and engineering design parameters at a specific level of detail. As the design parameters are refined, the engineering and land planning facts may change necessitating a change in the cost estimate.

Incremental real estate costs are estimated at 20 percent of required real estate costs (flowage easements, flood protection levee easements, and temporary work area easements) for risk-based contingencies.

Incidental acquisition costs are estimated to include NFS costs incurred for title work, appraisals, review of appraisals, coordination meetings, review of documents, legal support, and other costs that are incidental to project LERRDs as well as Government costs for staff monitoring and reviewing and approving LERRDs. Incidental Government costs are estimated for NFS monitoring as well as LERRDs certification.

10. Public Facility and Utility Relocations

A preliminary review of civil and geotechnical engineering information and aerial maps indicate, at this phase of design, utility relocations are anticipated along the Koali Road Floodwall, Ala Wai Golf Course Detention Basin, and the Ala Wai Canal Floodwall. Given the densely populated residential area surrounding, it is not likely that these utilities can be relocated within existing easement rights of way. See Table 10-1: Estimated Utility Relocations and Figure 10-1: Koali Road Floodwall Utility Locations.

Table 10-1: Estimated Utility Relocations

Measure	No. of Utility Relocations			
	Sewer	Water	Gas	Power
Koali Road Floodwall	1,100LF	2x65LF	0	8x65LF
Ala Wai Golf Course Detention	4x100LF	0	0	6x100LF
Ala Wai Canal Floodwall	28x65LF	16x65LF	4x65LF	22x65LF

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

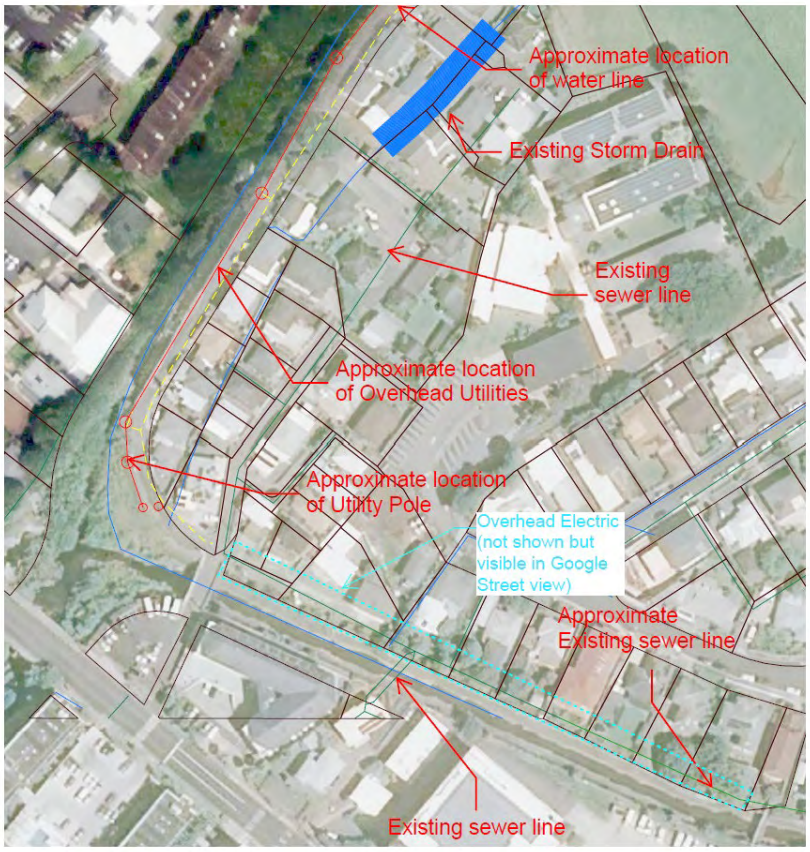

Figure 10-1: Koali Road Floodwall Utility Locations

11. Public Law 91-646 Relocation Benefits

Both residential and commercial structures are anticipated to be affected by the placement of structural project features, thus necessitating relocation benefits. The Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970, PL 91-646, as amended, commonly called the Uniform Act, is the primary law for acquisition and relocation activities on Federal or federally assisted projects and programs. The NFS is required to follow the guidance of PL 91-646 regarding the displacement of towns, businesses, farms, or persons as well as habitable and commercial structures. Five commercial and residential structures are anticipated to be relocated due to the Woodlawn Bridge Floodwall, Koali Road Floodwall, and Ala Wai Canal Floodwall. As illustrated in Table 11-1: Estimated Residential and Commercial Relocations below, the value of the five structures, including the cost of relocation benefits, is estimated at $5,299,900.

Table 11-1: Estimated Residential and Commercial Relocations

Measure	Property Type	Acreage	Estimated Value

Woodlawn Bridge Floodwall	Commercial	0.01	$17,500
Koali Road Floodwall	Residential	0.14	$1,292,300
Ala Wai Canal Floodwall	Commercial	0.02	$189,100
	Residential	0.03	$2,817,200
	Residential	0.01	$933,800
Relocation Benefits			$50,000
TOTAL			**$5,299,900**

12. Minerals, Timber, and Crop Activity

Based on a review of the Geotechnical Appendix, currently, there is insufficient boring coverage for design purposes at every measure location. Borings and laboratory testing to confirm soil and rock conditions at each specific feature location will be required to develop more specific designs.

In accordance with Hawaii Revised Statutes (HRS) §182-2, all mineral rights within the State of Hawaii are reserved for the State (HRS §182-2, 2014). Acquisition of an interest in land conveys no right, title, or interest in or to the minerals.

Additionally, no known timber or crops are anticipated to be affected by the proposed project.

13. Assessment of Sponsor's Acquisition Capability

An Assessment of the NFS's Real Estate Acquisition Capability will be conducted jointly with the NFS in preparation for the final Real Estate Plan. A sample Sponsor's Acquisition Capability Assessment is included in Attachment 1.

14. Zoning

No enactments of zoning ordinances are proposed in lieu of, or to facilitate, acquisition in connection with the proposed project. Zoning within the project footprint is predominantly Preservation and Residential (Hawaii DPP, 2023).

15. Acquisition Milestones

Given the proposed Project potentially affects over 40 private property owners, the following preliminary schedule estimates twenty-four (24) months for NFS LERRDs planning and acquisition. A final planned timeline below will be mutually agreed upon by USACE Real Estate, Project Management, and the NFS.

The NFS's preliminary acquisition planning is estimated at six (6) months as follows:

Survey/Map/Title	90 Days
Legal Description	30 Days
Appraisal	60 Days

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

The NFS's LERRDs acquisition is estimated at eighteen (18) months as follows:

Documentation	120 Days
Negotiation	180 Days
CCH Approval	120 Days
Payment	60 Days
LERRD Certification	60 Days

16. Environmental Impacts

Potential environmental impacts resulting from the proposed project are being considered, including investigation under the NEPA/HEPA, HTRW policy, National Historic Preservation Act, Archaeological and Historic Preservation Act, Clean Water Act, Endangered Species Act, Farmland Protection Policy Act, Fish and Wildlife Coordination Act, Migratory Bird Treaty Act, Native American Graves and Repatriation Act, Noise Control Act, Plant Protection Act, Rivers and Harbors Act, and Magnuson-Stevens Fishery Conservation and Management Act.

National Environmental Policy Act (NEPA)

It is assumed that an Environmental Assessment is the appropriate NEPA document for the final array of alternatives. Environmental analysis will comply with all environmental laws applicable. Analysis will be completed by relying on existing literature, remote sensing technologies, and data available from other agencies for use in GIS.

Hazardous, Toxic, and Radioactive Waste (HTRW) Policy

In the 2017 Ala Wai Canal Flood Risk Management EIS, an assessment identified a variety of HTRW sites within the Mānoa watershed. Additional information regarding the assessment results is provided in the Final Reconnaissance Phase Hazardous, Toxic, and Radioactive Waste Assessment for the Ala Wai Watershed Project (Myounghee Noh and Associates, 2009).

Based on the findings of the HTRW Appendix, which included a review of historical data and environmental records, there are currently no specific sites that are anticipated to prevent implementation of the project. However, the proposed work is within a dense urban area, and recognized environmental conditions (RECs) or sites with unresolved issues were identified in proximity to various project features. Depending on the final alignment of project features and on the extent of construction excavation, it is possible that some sites may have impacted soils or groundwater.

It is recommended that environmental contamination database results be reviewed during PED. Targeted soil sampling as part of a Phase II investigation is recommended for any areas requiring excavation that have identified specific impacts or potential impacts.

National Historic Preservation Act (NHPA)

In accordance with Section 106 of the NHPA, cultural and historic resources for the Ala Wai watershed were originally evaluated in the context of a National Historic Preservation Act Programmatic Agreement (PA) between USACE, the Hawai'i State Historic Preservation Office, the State of Hawai'i Department of Land and Natural Resources, the Oahu Island Burial Council, the Office of Hawaiian Affairs, and Historic Hawai'i Foundation. The PA details

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

procedures to be utilized to evaluate project effects and determine appropriate and mutually agreeable mitigation and treatment approaches for known or inadvertently discovered historic properties. The Ala Wai PA was fully executed on November 16, 2016, and remains in effect for seven years.

A historic structures inventory survey was conducted in 2010 for the Ala Wai watershed to inform the analysis in the 2017 Ala Wai Canal Flood Risk Management EIS. The inventory identified a variety of structures dating from 1965 or earlier, including bridges, culverts, channel modifications, dams, and water supply structures.

17. Landowner Concerns

Private landowner concerns are anticipated in the project footprint and Study area due to the potentially large number of privately-owned parcels that could be affected. Multiple stakeholder and agency meetings and other public involvement efforts have been conducted throughout the planning process.

In general, stakeholders have expressed support for the project and emphasized the need for near-term action to reduce the risk of flooding.

18. Notification to Sponsor

The NFS, CCH, is involved in the planning process and supportive of the project. The NFS will be provided a Local Sponsor Toolkit and advised of the risks of acquiring LERRDs before the execution of the PPA. A Sample Letter Advising Against Early Acquisition is included in Attachment 2.

Additionally, once the LERRDs are finalized, a Notice to Acquire Letter will be transmitted to the NFS. The Notice to Acquire Letter serves as the formal instruction for the NFS to acquire the real estate interests needed for the proposed project. A Sample Notice to Acquire Letter is included in Attachment 3.

19. Other Relevant Real Estate Issues

There are no other known relevant real estate issues in the Study area.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Attachment 1: Sponsor's Acquisition Capability Assessment

Assessment of Non-Federal Sponsor's Real Estate Acquisition Capability

Project: Ala Wai General Reevaluation Report
Project Authority: Section 209 of the Flood Control Act of 1962 (Public Law 87-874) and Section 216 of the Flood Control Act of 1970, as amended
Non-Federal Sponsor: City and County of Honolulu
Name, Title
Address
Phone, email

Legal Authority	**Yes**	**No**
1. Does the NFS have legal authority to acquire and hold title to real property for project purposes? (statutory citation)		
2. Does the NFS have the power of eminent domain for the project (statutory citation)		
3. Does the NFS have "quick-take" authority for this project?		✓
4. Are there any lands/interests in land required for the project that are located outside the NFS's authority boundary?		
5. Are any of the lands/interests in land required for the project owned by an entity whose property the sponsor cannot condemn?		
6. Will the NFS's in-house staff require training to become familiar with the real estate requirements of Federal projects, such as PL 91-646, as amended?		✓
7. If #6 is yes, has a reasonable plan been developed to provide training?		NA

Willingness to Participate	**Yes**	**No**
8. Has the NFS stated its general willingness to participate in the project and its understanding of the general scope and role?		
9. Is the NFS agreeable to signing a Project Partnership Agreement and supplying funding as stipulated in the agreement?		
10. Was the NFS provided the Local Sponsor Toolkit? Date		

Acquisition Experience and Capability	**Yes**	**No**
11. Taking into consideration the project schedule and complexity, does the NFS have the capability, with in-house staffing or contract support, to provide the necessary services, including surveying, appraisal, title, negotiation, condemnation, closing, and relocation assistance, as required for the project?		
12. Is the NFS's projected in-house staffing level sufficient considering its workload?		
13. Can the NFS obtain contractor support, if required, in a timely manner?		
14. Is the NFS's staff located within reasonable proximity to the project site?		
15. Will the NFS likely request USACE assistance in acquiring real estate?		

Schedule Capability	**Yes**	**No**
16. Has the NFS approved the tentative project real estate schedule and indicated its willingness and ability to utilize its financial, acquisition, and condemnation capabilities to provide the necessary project LERRDs in accordance with the proposed project schedule so the Government can advertise and award a construction contract as required by overall project schedules and funding limitations? The anticipated NFS real estate acquisition timeframe for the project is twenty-eight (28) months. **NFS Initials:**		

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

LERRD Crediting	Yes	No
17. Has the NFS indicating its understanding of LERRD credits and its capability and willingness to gather the necessary information to submit LERRD credits within six (6) months after possession of all real estate and completion of relocations so the project can be financially settled? **NFS Initials:**		

Past Action and Coordination	Yes	No
1. Has the NFS performed satisfactorily on other USACE projects?		
2. Has the assessment been coordinated with NFS?		
3. Does the NFS concur with the assessment? (provide explanation if no)		

With regard to the project, the NFS is anticipated to be:	Select One
Fully Capable: previous experience; financial capability; authority to hold title; in-house staff can perform necessary services (survey, appraisal, title, negotiation, closing, relocation assistance, condemnation) as required by the LERRDs.	
Moderately Capable: financial capability; authority to hold title; can perform, with contract support, necessary services (survey, appraisal, title, negotiation, closing, relocation assistance, condemnation) as required by the LERRDs.	
Marginally Capable: financial capability; authority to hold title; will rely on approved contractors to provide necessary services (survey, appraisal, title, negotiation, closing, relocation assistance, condemnation) as required by the LERRDs.	
Insufficiently Capable (provide explanation): financial capability; will rely on another entity to hold title; will rely on approved contractors to provide necessary services (survey, appraisal, title, negotiation, closing, relocation assistance, condemnation) as required by the LERRDs.

SUBJECT: Ala Wai Watershed Integrated Feasibility Report, Risks of Early Acquisition

Name
Title, Office
Address
City, State

Dear xx:

Reference is made to the Ala Wai Integrated Feasibility Report (Study) as authorized under Section 209 of the Flood Control Act of 1962 (Public Law 87-874) and Section 216 of the Flood Control Act of 1970, as amended. The City and County of Honolulu, as the Non-Federal Sponsor, is responsible for ensuring that it possesses the authority to acquire and hold title for all real property required for the proposed project. The Non-Federal Sponsor shall provide one hundred percent (100%) of the lands, easements, rights-of-way, utility or public facility relocations, and dredged or excavated material disposal areas (LERRDs) as well as operation, maintenance, and repair required by the project.

The United States Army Corps of Engineers, Honolulu District, advises your office that there are risks associated with the acquisition of LERRDs prior to the execution of a Project Partnership Agreement (PPA) or Local Cooperation Agreement (LCA). The City and County of Honolulu will assume full and sole responsibility for any and all costs and liabilities arising out of premature acquisition. Project risks generally include, but are not limited to:

a. Congress may not appropriate funds to construct the proposed project;
b. The proposed project may otherwise not be funded or approved for construction;
c. A PPA/LCA mutually agreed to by the Non-Federal Sponsor and the Government may not be executed;
d. The Non-Federal Sponsor may incur liability and expense by virtue of its ownership of contaminated lands, or interests therein, whether such liability should arise out of local, state, or Federal laws or regulations, including liability arising out of the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), as amended;
e. The Non-Federal Sponsor may acquire interest or estates that are later determined by the Government to be inappropriate, inefficient, or otherwise not required for the project;
f. The Non-Federal Sponsor may initially acquire insufficient or excessive real property acreage, which could result in additional negotiations and or/benefit payments under Public Law 91-646 or additional payment of fair market value to affected landowners;
g. The Non-Federal Sponsor may incur costs or expenses in connection with its decision to acquire LERRDs in advance of the executed PPA/LCA and the Government's Notice to Acquire (NTA).

March 23, 2023

Real Estate Division

SUBJECT: Ala Wai Watershed Integrated Feasibility Report, Notice to Acquire

Name
Title, Office
Address
City, State

Dear xx:

This letter serves as your Notice to Acquire the real estate interests required from the City and County of Honolulu for the Ala Wai Watershed Project (Project) as authorized under authorized under Section 209 of the Flood Control Act of 1962 (Public Law 87-874) and Section 216 of the Flood Control Act of 1970, as amended. Enclosed are the final Authorization for Entry for Construction, Attorney's Certificate of Authority, and project real estate drawings. Also enclosed is the standard language to be used for the required conveyance documents between the City and County of Honolulu, as the Non-Federal Sponsor, and landowners.

In accordance with the Project Partnership Agreement (PPA) dated xx, the City and County of Honolulu shall provide the real property interests and relocations required for the construction, operation, and maintenance of the project. As required by the PPA, the Government has determined the Flood Protection Levee Easements and Temporary Work Area Easements as shown on the real estate drawings are required for project implementation. The PPA also requires the City and County of Honolulu to comply with the Uniform Relocations and Assistance and Real Property Acquisition Policies Act. 42 U.S.C. § 4601, et. seq., and the Uniformed Regulations, 49 C.F.R. part 24. More information can be found at http://www.fhwa.dot.gov/realestate/realprop.

After acquisition of the required real estate interests, the City and County of Honolulu shall complete and sign the Authorization for Entry for Construction and Attorney's Certificate of Authority. Please return the original signed authorization documents to the Corps of Engineers, Honolulu District Real Estate Division, by mail to the address contained in the letterhead. In addition, the City and County of Honolulu shall provide copies of all conveyance documents for required real estate acquisitions to the Corps of Engineers. The Corps of Engineers requires the conveyance documents prior to advertising a construction contract. Copies of conveyance documents may be scanned and submitted electronically to the contact person below.

If you have any questions, please contact Tiffany Murray, Realty Specialist, at (808) 835-4065 or tiffany.murray@usace.army.mil.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

1. Introduction

The purpose of this report is to discuss the hazardous, toxic, and radioactive waste (HTRW) investigation for the Ala Wai Canal General Reevaluation Report. This report identifies both HTRW and non-HTRW environmental issues and presents appropriate measures to avoid or resolve these issues. The methods used in performing the investigation are described below. Conclusions and recommendations regarding potential impacts due to HTRW, non-HTRW, and recognized environmental conditions (RECs) associated with the project site are provided.

The Tentatively Selected Plan (TSP) is the proposed action. The TSP is made up of measures, also referred to as project features, to minimize the extent of flooding within the Ala Wai watershed during frequent storm events.

The project site, also referred to as the project footprint in other parts of this report, encompasses the physical location of the proposed action and all included measures or project features, either individually or collectively, which includes the Ala Wai Canal and Manoa-Palolo Canal and portions of adjacent uplands along these areas as well as upland areas along Manoa Stream (Woodlawn Drive floodwall) and the Manoa and Palolo streams (Koali Road floodwall) that will be impacted to facilitate construction associated with the TSP shown in Figure 29: Conceptual Diagram of Alternative 5.3 in the main body of the report.

2. Authority

Engineer Regulation (ER) 1165-2-132, Hazardous, Toxic, and Radioactive Waste (HTRW) Guidance for Civil Works projects, requires that a site investigation be conducted as early as possible to identify and evaluate potential HTRW problems. According to ER 1165-2-132, non-HTRW issues that do not comply with the federal, state, and local regulations should be discussed in the HTRW investigation along with HTRW issues. Therefore, HTRW and non-HTRW issues identified are discussed in this report.

The HTRW investigation presented in this report was conducted during the evaluation of alternatives phase of the project. This investigation relies on existing information, observations made through database research, and a historical aerial photograph and topographic map review. As stated in the ER- 1165-2-132, an initial assessment as appropriate for a Reconnaissance Study should be conducted as a first priority for projects with no prior HTRW consideration. If the initial assessment indicated the potential for HTRW, testing, as warranted, and analysis similar to a Feasibility Study, or Phase II Environmental Site Assessment (ESA), should be conducted prior to proceeding with the project design.

No HTRW investigation can wholly eliminate uncertainty regarding the potential for HTRW associated with a project area. Performance of the HTRW investigation is intended to reduce, but not eliminate, uncertainty regarding the potential for HTRW in connection with a project area, and this practice recognizes time and cost constraints.

3. Guidance

Supplemental guidance was provided by the Standard Practice for Environmental Assessments: Phase I Environmental Site Assessment Process (Designation: E 1527-21) prepared by the American Society for Testing of Materials (ASTM). The purpose of this guidance is to define

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

good commercial and customary practice in the United States of America for conducting an environmental site assessment of a parcel of commercial real estate with respect to the range of contaminants within the scope of the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA) (42 U.S.C. §9601) and petroleum products. These standards include a records review, site visit, interviews, and report preparation. This report followed many of the ASTM E 1527-21 guidelines but not to the same level of detail described by the ASTM E 1527-21 guidance.

3.1. Hazardous, Toxic, and Radioactive Waste

The objective of ER 1165-2-132 is to outline procedures to facilitate early identification and appropriate consideration of HTRW problems. This investigation, therefore, identifies potential HTRW problems and discusses resolutions and/or provides recommendations regarding the HTRW problems identified.

3.2. Non-Hazardous, Toxic, and Radioactive Waste

According to ER 1165-2-132, non-HTRW environmental issues that do not comply with federal, state, and local regulations should be discussed in the HTRW investigation along with HTRW issues. For example, solid waste is a non-HTRW issue considered, in addition to petroleum releases from Leaking Underground Storage Tanks (LUSTs), because of the potential to impose environmental hazards. Non-HTRW and RECs identified during the investigation are also discussed in this report, along with resolutions and/or recommendations for resolving any open issues.

3.3. Recognized Environmental Condition

For the purposes of this investigation, the term REC may be used interchangeably with HTRW to identify a potential HTRW or non-HTRW environmental issue. ASTM defines a recognized environmental condition (REC) as the presence or likely presence of any hazardous substances or petroleum products in, on, or at a property: (1) due to release to the environment; (2) under conditions indicative of a release to the environment; or (3) under conditions that pose a material threat of a future release to the environment. *De minimis* conditions are not RECs.

4. Laws and Regulations

4.1. Federal

The definition of HTRW according to ER 1165-2-132, page 1, paragraph 4(a) is as follows: “Except for dredged material and sediments beneath navigable waters proposed for dredging, for purposes of this guidance, HTRW includes any material listed as a ‘hazardous substance’ under the Comprehensive Environmental Response, Compensation and Liability Act, 42 U.S.C. 9601 et seq (CERCLA). (See 42 U.S.C. 9601(14).) Hazardous substances regulated under CERCLA include ‘hazardous wastes’ under Sec. 3001 of the Resource Conservation and Recovery Act, 42 U.S.C. 6921 et seq; ‘hazardous substances’ identified under Section 311 of the Clean Air Act, 33 U.S.C. 1321, ‘toxic pollutants’ designated under Section 307 of the Clean Water Act, 33 U.S.C. 1317, ‘hazardous air pollutants’ designated under Section 112 of the Clean Air Act, 42 U.S.C. 7412; and ‘imminently hazardous chemical substances or mixtures’ on which EPA has taken action under Section 7 of the Toxic Substance Control Act, 15 U.S.C. 2606; these do not include petroleum or natural gas unless already included in the above categories. (See 42 U.S.C. 9601(14).)”

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

As noted in 42 U.S.C. 9601(14), the term “hazardous substance” does not include petroleum, including crude oil or any fraction thereof, which is not otherwise specifically listed or designated as a hazardous substance, nor does the term include natural gas, natural gas liquids, liquefied natural gas, or synthetic gas usable for fuel. Underground Storage Tanks (USTs) are federally regulated under 40 CFR Part 280, which includes technical standards and corrective action requirements for owner and operators of USTs.

4.2. State

The Hawaii State regulations were examined to determine which regulations governed the state specific hazardous waste disposal, release, and cleanup requirements. Hawaii regulates underground storage tanks under the Hawaii Administrative Rules (HAR) Title 11, Chapter 11-280.1 Underground Storage Tanks. This rule regulates all underground storage tanks except those that hold hazardous waste (regulated under chapter 342J of the Hawaii Revised Statutes (HRS), wastewater treatment tank systems regulated under Chapter 342D of the HRS, equipment or machinery tanks, any UST system smaller than 110 gallon capacity, any UST that contains a *de minimis* concentration of regulated substances, or any emergency spill or overflow containment that is expeditiously emptied after use. The rule also partially excludes aboveground storage tanks associated with airport hydrant fuel distribution or UST systems with field-constructed tanks, UST systems containing radioactive material regulated under the Atomic Energy Act of 1954, and any UST that is part of an emergency generator system at nuclear power generation facilities. “Underground storage tank" or "UST" is defined as any one or combination of tanks (including underground pipes connected thereto) that is used to contain an accumulation of regulated substances, and the volume of which {including the volume of underground pipes connected thereto) is ten percent or more beneath the surface of the ground. The Hawaii Department of Health (HiDOH) administers the UST program.

Solid waste in Hawaii is covered under HAR Title 11, Chapter 11-58.1 Solid Waste Management Control. The rule establishes minimum standards for the design, construction, installation, operation and maintenance of solid waste disposal, recycling, reclamation and transfer systems. Under this rule "solid waste" or "waste" means garbage, refuse, and other discarded materials, including solid, liquid, semi-solid, or contained gaseous materials resulting from industrial, commercial, mining, and agricultural operations, sludge from waste treatment plants and water supply treatment plants, and residues from air pollution control facilities and community activities, but does not include solid or dissolved materials in domestic sewage or other substances in water sources such as silt, dissolved or suspended solids in industrial waste water effluents, dissolved materials in irrigation return flows, or other common water pollutants, or source, special nuclear, or by-product material as defined by the federal Atomic Energy Act of 1954. "Hazardous waste" means regulated hazardous waste as defined in 40 CFR 261 or the State of Hawaii's rules or statutes, whichever is more stringent.

Hazardous Waste is regulated under HAR Title 11, Chapter 11-260.1 Hazardous Waste Management. The hazardous waste rules follow the federal regulations, with some changes in terminology and with state specific reporting requirements. Similar to the federal regulations, Hawaii regulates specific (listed) wastes, characteristic wastes, waste oil and universal wastes. Hawaii has established liability requirements and permitting procedures for the handling, transportation and disposal of hazardous wastes.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

5. Study Description

The Ala Wai Watershed is located on the southeastern side of the island of Oahu, Hawaii. The watershed encompasses 19 square miles (12,064 acres) and extends from the ridge of the Koolau Mountains to the nearshore waters of Mamala Bay (Figure 5-1). It includes the Makiki, Manoa, and Palolo streams, which flow to the Ala Wai Canal, a 2-mile-long, man-made waterway constructed during the 1920's to drain extensive coastal wetlands. The construction and subsequent draining allowed the development of the Waikiki District.

The proposed action involves project improvements planned at several urban locations within the lower reach of Manoa stream and the Ala Wai Canal to manage flood waters and reduce the risk of flood-related effects to residential and commercial communities. The project is considered the proposed action to convey flood waters through the watershed and Ala Wai Canal and includes a number of individual features. The alternatives that were under consideration at the time of this HTRW investigation are described below. The designs for the individual features included in the alternatives are not fully developed, but in general it is expected that some level of earth disturbing activities would be needed at each location. Because the design details, including the alignment of features, are expected to change during the development of the design, it is recommended that the HTRW investigation be reviewed during design phase, to document any new impacts due to changes in the project features and/or from condition changes at adjacent properties.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Figure 5-1: Ala Wai Watershed (Study Area)

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

6. Alternatives Description

The alternatives being evaluated in this study are described very briefly below, for context. Full descriptions of the features can be found in the main report. The areas around the identified features were evaluated for this investigation. There are three main alternatives; some features are common across the alternatives, but the details of individual features may differ.

6.1. Storage Cornerstone Alternative.

The Storage Cornerstone alternative includes several temporary storage basins which would hold waters until the downstream drainage features could transport the flow. Implementation of this alternative would include the construction of several detention basins and floodwalls in strategic locations. Figure 6-1 shows the feature locations. The proposed features include:

- The Makiki District Park detention basin
- The Manoa Valley District Park detention basin
- The Ala Wai Golf Course detention basin
- The Kaimuki High School berm/floodwall
- The Kanaha floodwall
- The Woodlawn Drive floodwall
- The Koali Road floodwall
- Inlet and outlet culverts at detention ponds

6.2. Conveyance Cornerstone Alternative

The Conveyance Cornerstone alternative focuses on improving stormwater conveyance by the addition of floodwalls and culverts. The proposed features are shown in Figure 6-2 and include:

- The Woodlawn Drive floodwall
- The Ala Wai Canal floodwall
- The Kanaha floodwall
- The Makiki District Park detention basin
- The Koali Road floodwall
- The Kaimuki High School berm/floodwall
- Inlet and outlet culvers at several locations

6.3. Hybrid Alternative

They Hybrid Alternative focuses on a combination of increasing storage and increasing conveyance throughout the watershed to reduce flood risk. Implementation of this alternative would include the construction of several detention basins and floodwalls in strategic locations. Figure 6-3 shows the proposed features; all these features are also included in at least one of the other alternatives. The list of features for the Hybrid Alternative includes:

- The Manoa Valley District Park detention basin
- The Ala Wai Canal floodwall
- The Woodlawn Drive floodwall
- The Kanaha floodwall

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

- The Makiki District Park detention basin
- The Koali Road floodwall
- The Ala Wai Golf Course detention basin
- Inlet and outlet culvers at several locations

6.4. Non-structural Alternative

Non-structural solutions are also being evaluated. It is important to note that non-structural alternatives would not include any in-stream work or nearshore work. Non-structural alternatives include measures such as floodproofing, removing structures from the floodplain, dry proofing structures, and early flood warning systems. The locations for non-structural alternatives are not yet determined, and the details of this alternative would be developed during a later project phase. Phase I HTRW investigations would need to be conducted for those locations and specific actions, depending on the proposed measure. Non-structural alternatives are not considered further in this evaluation.

7. General Methods

The following sections contain information that was gathered in accordance with ER 1165-2-132 for this assessment. The information was obtained from:

- Regulatory documentation
- Existing information review
- Historic topographic map and aerial photograph review
- Database research

This information was used to determine if proposed actions are likely to encounter HTRW or other environmental issues which would require resolution prior to project implementation, or which could prevent project implementation. The information gathered from the above list of sources is detailed in the following sections.

8. Records Review

8.1. Historical Map and Aerial Photography Review

Historical maps and aerial photos were reviewed to determine changes in land use or development that would indicate the potential for legacy pollution issues or that may indicate unresolved environmental conditions. It is noted that the Ala Wai Canal was developed earlier than the oldest available historical maps and photos; the project area was already an urban environment by the 1920's, when documentation begins.

8.1.1. Historical Topographic Maps

Historical U.S. Geological Survey (USGS) maps from 1928, 1953, 1954, 1959, 1969, 1970, 1978, 1983, 1998, 2013, and 2017 were reviewed for changes in the project area. The review focused on the locations of the specific project features for the three alternatives, and also noted general trends in land use over time.

8.1.1.1. 1928

The Ala Wai Canal is in the current, channelized condition by 1928. The area around the canal outlet is much less developed, and current marinas and infrastructure do not exist. South of the canal, the Kapiolani Park exists in approximately the current boundary. The city has a much smaller footprint than the current conditions. Lands in the Manoa Valley and around Punch Bowl crater and the Round Top Forrest Preserve contain only a few structures. The land that is currently the Ala Wai Golf Course is undeveloped. An area is designated "University of Hawaii" but is largely undeveloped land.

8.1.1.2. 1953/1954

By 1953, the Ala Wai Golf Course is noted on the map, and additional roads have extended into the foothills, particularly in the Manoa Valley and east of Punch Bowl crater. The developed area east of Punch Bowl crater is now labeled Makiki Heights The Kaimuki High School is shown in the current location, adjacent to the golf course. Northwest of the high school and connecting to the Ala Wai Canal is a constructed drainage canal (Manoa-Palolo drainage canal in later maps). North of the high school and across the "Malika Arterial" (now Interstate H-1) is

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

the Mõ'ili'ili quarry, adjacent to the south side of the University of Hawaii. It does not appear that the drainage canal is connected to the quarry. Development has filled in around the university. The Ala Wai Canal now has a yacht harbor at the outlet, smaller than the current marina but in a similar orientation. Starting in 1953, the map indicates beach and offshore reef areas along the coast and south of the Ala Wai Canal. The main difference between the 1953 and 1954 maps appears to be coloration, with the 1954 map using different shading that is somewhat more legible.

8.1.1.3. 1959

The 1959 map is similar to the 1954 map. Additional development is shown, for example in the area of the quarry which now includes several larger structures, a grouping of small structures along roads, and includes the sub-designation of "athletic field." Development continues to extend outward along the valleys. Near Diamond Head, some additional developed areas are shown; these locations previously contained some structures but are now incorporated into the city development. Overall, there do not appear to be dramatic changes to the area.

8.1.1.4. 1969/1970

By 1969, the Manoa Valley has filled in, and former open areas are now developed. The area of the University has also developed and the quarry area, still labeled "quarry (athletic field)," is further developed. The yacht club at the Ala Wai Canal outlet has expanded to something similar to the current condition, and the shoreline south of the outlet has additional beach areas designated; former parks and beaches remain in the same configuration. The 1970 map appears to contain the same information as the 1969 map, but with different coloration and fonts; the 1970 map is less legible than the 1969 map. In the 1970 map, the former quarry area is no longer designated as a quarry.

8.1.1.5. 1978

The 1978 map is actual a black and white aerial photo. The photo is unlabeled. Aside from the Punchbowl crater, Makiki hills, and St. Louis Heights, the project area appears densely developed by this time.

8.1.1.6. 1983

The 1983 map returns to the more typical USGS topographic map format. Major features appear the same, with no apparent changes to the Ala Wai canal, drainage canal, golf course, parks or other features. The proposed project areas appear to be in similar condition to current conditions. A few new areas appear to have been incorporated into the city, but these areas were already at least partly developed by 1970 and do not represent a large change in land use. The former quarry is again designated "quarry (athletic field)" and appears to be fully developed for non-quarry purposes.

8.1.1.7. 1998

The 1998 map has new coloration, but few other apparent changes. The "Mõ'ili'ili quarry (athletic field)" is still labeled as such, although clearly developed. The drainage canal is now labeled "Mãnoa-Pãlolo Drainage Canal."

8.1.1.8. 2013

The 2013 map has again changed coloration, and additional shoreline features (beaches) are labeled. Upland the labeling is streamlines; schools and parks are no longer titled on the map but symbols denote their presence. The quarry and university are not labeled.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

8.1.1.9. 2017

The 2017 map is very similar to the 2013 map. The Ala Wai golf course is labeled “Hawaii Administrative Site” in this map. Punchbowl crater is now labeled “National Memorial Cemetery of the Pacific.” The University of Hawaii Manoa is labeled. Overall the map shows the project area in the current configuration. In general, the project location was developed by the 1970’s and major features and land uses appear to date from that time period.

8.1.1.10. Historical Map Conclusions

The project area was largely developed by the time of the first map. Major features, including the Ala Wai canal, the Ala Wai golf course, Kapiolani Park, and Manoa Park District were present in the current locations since 1928 – 1953. These major features do not appear to have previous land uses. The project area is an urban area, and the historical maps show multiple changes within the city. Proposed floodwalls and other project features are within the urban footprint.

8.1.2. Historical Aerial Photographs

Aerial photographs from 1951, 1959, 1968, 1974, 1975, 1978, 1985, 1992, 2006, 2011, 2015, and 2017 were reviewed. The project area is sufficiently large that three photos were needed to cover the entire area. Except as noted below, three images covering the same extents were available for all years.

8.1.2.1. 1951

The 1951 photographs are black and white, of good quality. By 1951, the project area is already quite developed, and many features appear in their current configuration. The Ala Wai canal, the Manoa-Palolo drainage canal and Manoa stream appear to be in the same configuration (channelized and altered) as currently. The Ala Wai golf course is clearly a golf course, with sand bunkers, greens and other typical features clearly visible. Kapiolani Park is also clearly visible. The former quarry area (now part of the University of Hawaii land) is visible as an empty, disturbed area; there is no development in the area but no clear evidence of active open pit mining. The marina at the outlet of the Ala Wai Canal is a developed marina, but smaller than the current configuration.

8.1.2.2. 1959

The 1959 photographs are black and white, of good quality. By 1959, the marina at the outlet of the Ala Wai Canal has expanded, and the adjacent shoreline (to the south) has been filled in and developed. The former quarry area now has a large building on the north side, and a cluster of small buildings (houses) on the southwest side, with the center area appearing to be vegetated with dirt roads or trails. Some small areas within the city appear to be infilled.

8.1.2.3. 1968

The 1968 photographs are in black and white, of good quality. The marina has further developed and expanded by 1968. Major roadways (what is now Interstate H-1) appears expanded. The former quarry is further developed, with a track and large parking areas; much of the remaining area appears to be mowed grass or other maintained surface. The Manoa Valley area has filled in further; roads were already laid out in the area by 1951 but are now more fully developed with housing. The golf course and Kapiolani Park appear to have more and larger trees.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

8.1.2.4. 1974/1975

The 1974 photographs are colored with the vegetation appearing red (due to the reflection of infrared light). The marina at the Ala Wai Canal outlet is again expanded slightly, with more dense boat docking. Development at the former quarry site has expanded to include additional athletic fields. The portion of the photograph over Kapiolani Park is obscured by clouds and shadows. A small drainage channel has been added to the south end of the golf course (connecting to the Ala Wai Canal). The remainder of the project area appears similar to current conditions. The 1975 aerial photographs are very similar to the 1974 photos, except that the southern extent of the photos is not obscured by clouds and is much clearer.

8.1.2.5. 1978

The 1978 photographs are black and white, of good quality. Major features appear unchanged. The golf course is still clearly a golf course. The interior of Kapiolani Park has changed configuration, but the park limits remain the same. Overall, few changes are noted.

8.1.2.6. 1985

The 1985 aerial photos are black and white but are of poor quality. One of the photographs is badly faded for half of the photo; a second is cut off and only shows part of the extent. The visible features appear similar to the 1978 photos.

8.1.2.7. 1992

The 1992 aerial photographs are in black and white. The images are distorted on the top (north) side of the photos, and the northwestern corner is cut off one photo. Because the 1985 images are of poor quality, the 1992 photos were compared to the 1978 photos for identifying changes to the project area. The only significant new development is a new road into the foothills northeast of the University of Hawaii, in the St. Louis Heights area, and several large buildings and some new infrastructure. There appear to be few other changes to the project area.

8.1.2.8. 2006

The 2006 aerial photographs are in color. One of the three photos is a partial image. Overall, the images are quite similar to the 1992 photographs. With close examination, small changes (new buildings or redevelopments) are visible, however the general land use appears unchanged from earlier photos. The major watercourses and park/open areas appear the same as current configurations.

8.1.2.9. 2011/2015/2017

The aerial photographs from 2011, 2015, and 2017 are color images of good quality. Overall, the project area shows little change from previous photographs, and the major features are in a similar configuration as the current conditions.

8.1.2.10. Historical Photograph Conclusions

The project area was already largely developed by the time of the first aerial photos. Major features, such as the Ala Wai canal and golf course, and Kapiolani Park are visible in their current locations. Aside from regular urban development (and redevelopment), there are no land use changes or apparent major land impacts visible.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

8.2. Database Search

The project area is a large extent and contains a number of proposed features spread at some distance from each other. To facilitate the database search, instead of conducting a separate search using the standard search distances for each possible project feature, a single search covering the extent of the alternatives was conducted. Figure 8-1 shows the limits of the search.

For any database search, ASTM recommends minimum search distances depending on the nature of the site and regulatory program. Table 8-1 shows the recommended search distances. There were no sites listed on the National Priority List (NPL, also known as the Superfund list) or state equivalent within the project area. Based on the lack of those facilities, the evaluation of database returns focused on sites within approximately 1/2 mile of a proposed project feature.

Table 8-1: Minimum Search Distance for Federal and State Databases

Database	Approximate Minimum Search Distance (mi)
Federal NPL Site List	1.0
Federal CERCLIS List	0.5
Federal CERCLIS NFRAP site list	Property and Adjoining Properties
Federal RCRA CORRACTS	0.5
Facilities List	1.0
Federal RCRA non-CORRACTS	0.5
TSD Facilities List	0.5
Federal RCRA Generators List	Property and Adjoining Properties
Federal ERNS List	Property Only
State Equivalent NPL	1.0
State Equivalent CERCLIS	0.5
State Landfill/Solid Waste Disposal	0.5
Site Lists	0.5
State LUST Lists	0.5
State registered UST List	Property and Adjoining Properties

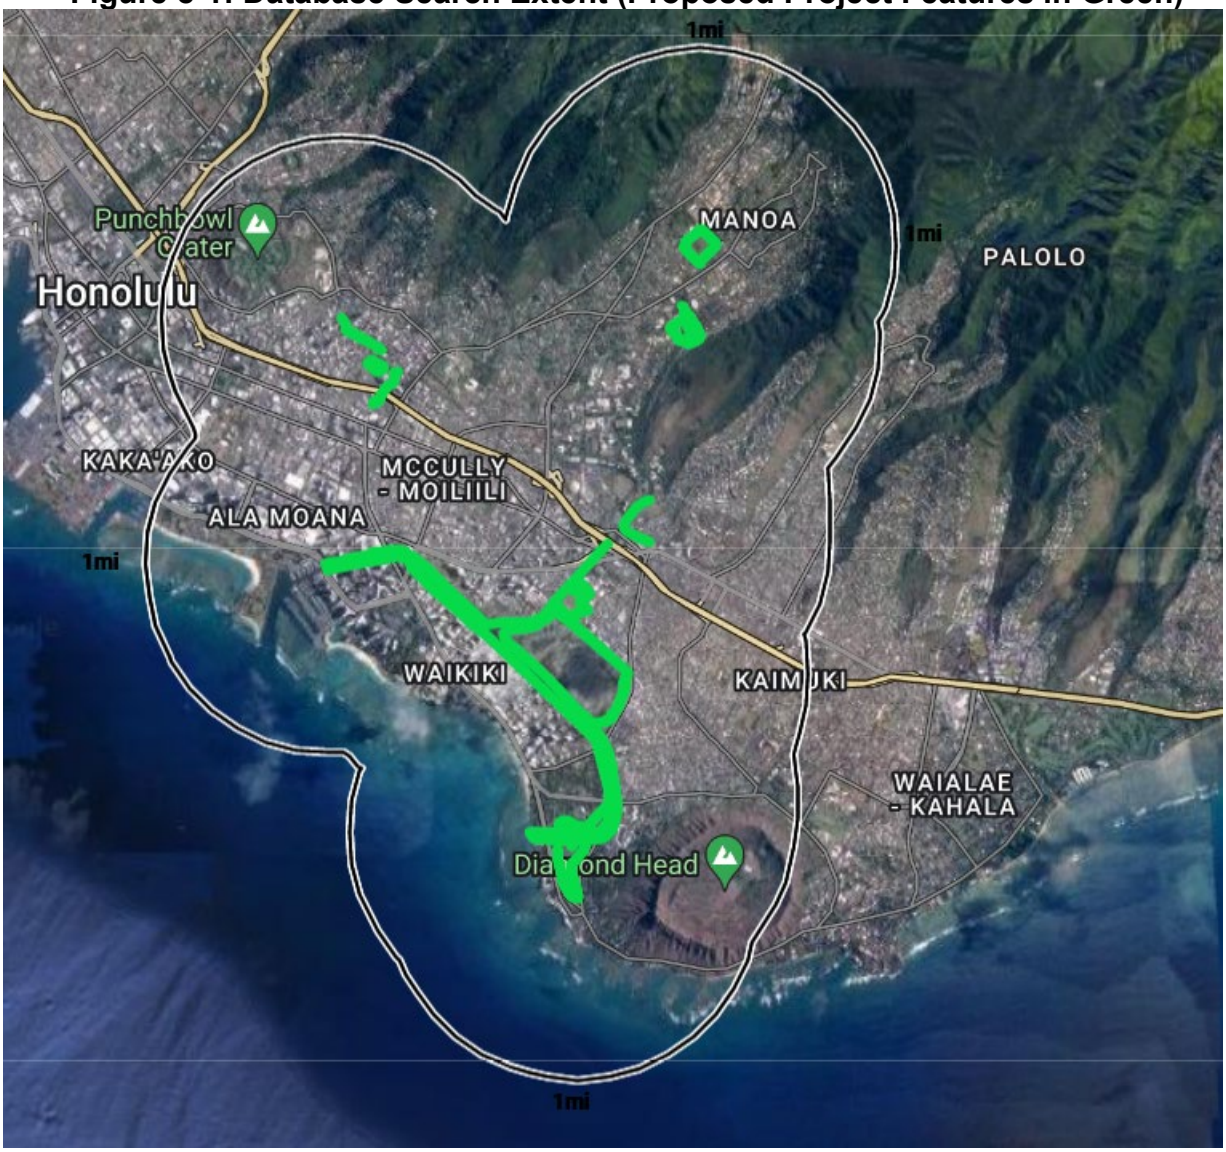
There were numerous database returns, which is expected in an urban area. To evaluate the significance of the potential sites, each individual feature included in any alternative was evaluated for impacts from the nearby sites. Note that due to the proximity of features, some database sites were evaluated for impacts to multiple features. Sites within approximately ½ mile of a feature were considered for impacts and are listed in a table summarizing returns for that feature.

Sites that were identified in the database return were also investigated using the Hawaii Department of Health “iHEER” (Hazard Evaluation and Emergency Response) system, which includes a portal of publicly available information. Additional details found on this website were used to evaluate the nature and extent of environmental issues, and to determine whether a

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

given site represents a potential impact to the proposed project activities. Information was not available on all sites.

Figure 8-1: Database Search Extent (Proposed Project Features in Green)



CONTROLLED UNCLASSIFIED INFORMATION (CUI)

8.2.1. The Makiki District Park Detention Basin

Makiki District Park is currently open land. The park is bordered on three sides by roads, and on the fourth side by office buildings. Construction of a detention basin would require excavation of the open land, conceptually up to a 10' depth. Sites within approximately ½ mile of the feature are shown in Figure 8-2. Database returns are listed in Table 8-2.

Figure 8-2: Makiki District Park Detention Basin Database Search Area

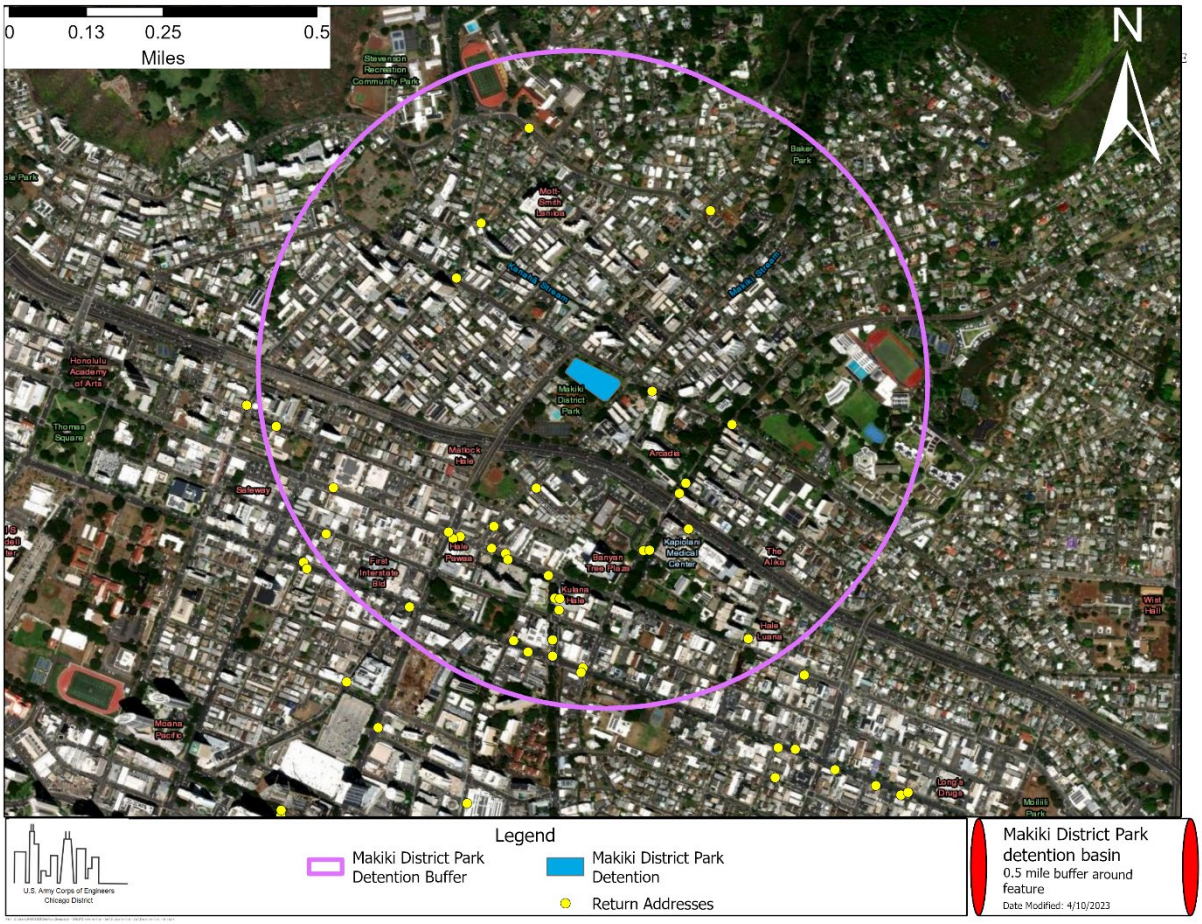


Table 8-2: Makiki District Park Detention Basin Database Returns

Site Name and address	Distance	Program or Issue	Status	Comments
Punchbowl Camp	1878 ft	FUDS	Site was a temporary housing for the Army Engineers battalion. The site contained an administrative office space for camp, two mess halls, a motor pool vehicle wash rack, latrines, barracks, tents, a supply room and post exchange. The site	No impact to project.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Site Name and address	Distance	Program or Issue	Status	Comments
			was returned to the state in 1944; there are no known installation or munitions related issues for the property.	
1653 Mott Smith Drive	1319 ft	SPILLS	1994 paint spill	Based on the nature of the spill there is likely no impact to the project.
Roosevelt High School Firing Range 1120 Nehoa St.	1956 ft	SHWS	Hazard undetermined; listed as a low priority brownfield site.	No impact to project.
Makiki Fire Station #3 1202 Wilder Ave	1190 ft	LUST, UST	LUST clean up complete 1995, 1 1000 gal UST in use, 1 500 gal UST permanently closed in 1991	No impact to project.
1911 Keeaumoku Street	1720 ft	SHWS	Pesticide and lead contaminated soils were removed in preparation for the expansion of the Hanahauoli School.	No impact to project.
Parish of St. Clement (St. Clement School) 1515 Wilder Ave	379 ft	RCRA, FFTS, Historic FFTS, ECHO, FINDS	Non RCRA generator as of 2021, former lead waste,	No impact to project.
Fire Hydrant Installations at Makiki St, Kamaia Dr, Manoa Rd, Oahu Ave, Pamoa	550 ft	NPDES	Point discharge locations	No impact to project.
Maryknoll High School 1402 Punahou St	725 ft	RCRA	CESQG	No impact to project.
Arcadia Retirement 1434 Punahou St	926 ft	LUST, UST	LUST clean up complete in 1999, 300 gal diesel tank permanently out of use in 1998	No impact to project.
Punahou School (Punahou School Firing Range) 1601 Punahou St	1394 ft	RCRA, LUST, UST, SHWS	CESQG (2017), LUST clean up complete 2007, confirmed release 2020, several UST permanently out of use with the last closure in 2020, hazards identified on site with controls required to manage contamination	No impact to project.
Punahou School	2468 ft	FUDS	The Punahou School was used by the Army Division as he headquarters for all aspects of the AED Administrative operations and including a medical unit, machine shop, supply storage, and motor transportation unit. There are no known installation or munitions related issues for the property.	No impact to project.
Kapiolani Medical Center for Women & Children 1637 Bingham St	1471 ft	UST	Two 20,000 gal diesel tanks in use	No impact to project.
Kapiolani Women's & Children's Medical Center 1319 Punahou St	1206 ft	SHWS, UST, AIRS, RCRA.	Two permanently out of service diesel tanks, boiler system using natural gas and fuel oil, CESQG with minor past violations	No impact to project.

Schuman Carriage Motors 1234 S Beretania St	2216 ft	SHWS, LUST, UST, INST CONTROL, SPILLS	transmission fluid and hydraulic fluid spills, 2 LUST clean up complete, 6 UST permanently out of use by 2005, site hazards managed by institutional controls	No impact to project.
Kaahumanu Elementary School 1141 Kinau St	2419 ft	SHWS	Building exterior soils. Part of a DOE study of schools. No issues identified.	No impact to project.
One Kalakaua Partners 1314 Kalakaua Ave	1788 ft	UST	1 UST permanently out of service	No impact to project.
Outrigger Hotels 1315 Kalakaua Ave	1812 ft	UST	1 UST permanently out of service as of 1991	No impact to project.
76 Kalakaua/Young 7-11 1323 Kalakaua Ave	1904 st	SHWS, UST	past waste issue with no further action letter, 2 UST in service (gasohol), several UST permanently closed	No impact to project.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Site Name and address	Distance	Program or Issue	Status	Comments
1414 Kalakaua Ave	2104 ft	SHWS, ENG CONTROLS, INST CONTROLS	Past soil and groundwater contamination issues, managed with on-going engineering and institutional controls. Site was remediated and closed in 2011.	This is now a multistory building site. Any issues appear to be under control. No impact to project.
Gas Plus 1524 S King St	2097 ft	LUST, UST	1 LUST clean up complete, 3 UST permanently out of use by 1995	No impact to project.
Mid Pac Petroleum (previously Lionel's Unocal) 1505 S King St	2321 ft	LUST, UST	3 LUST clean up complete, 5 UST permanently out of use by 2007	No impact to project.
1003 and 1013 Kaheka St	2149 ft	SHWS	Lead in ground (2-3' below ground surface), no further action letter issued since sampling indicates that exceedance is isolated and below parking lot.	No impact to project.
Punahou Repair Shop 1558 S King St	2266 ft	LUST, UST	LUST clean up complete, 3 UST permanently out of service by 1992	No impact to project.
Hele Kin Kalakaua 1549 S King St	2425 ft	LUST, UST	LUST clean up complete, 3 UST in use (gasohol), several UST permanently out of use	No impact to project.
Yajima Oil 1375 S King St	2525 ft	LUST, UST	LUST clean up complete, 3 UST in use (gasohol)	No impact to project.
Grace Otsuka Apartment 1233 Young St	2505 ft	SHWS, ENG CONTROLS, INST CONTROLS	Soil contamination with diesel (former UST location), engineering controls used to manage hazard; it is estimated that 10 cy of contaminated soil remain adjacent to and below the building.	No impact to project.
Cal's Cleaners 1234 S King St	2701 ft	SHWS	Dry cleaners, no apparent violations, apparently closed as of July 2022	No impact to project.

Based on a review of the database returns for sites within approximately ½ mile, there do not appear to be environmental impacts to the Makiki District Park site. Due to the depth and extent of excavation, it is recommended that the status of the detention basin site be reviewed during design phase. Soil re-use could require testing to ensure that the soils are suitable; soil re-use requirements were not evaluated here but should be considered during design.

8.2.2. The Manoa Valley District Park Detention Basin

The Manoa Valley District Park land is currently open land, surrounded by a school complex and residential development. Construction of the detention basis would conceptually include excavation up to 8' depth. Sites within approximately ½ mile of the feature are shown in Figure 8-3. The closest database returns (within approximately ½ mile) are listed in Table 8-3.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Site Name and address	Distance	Program or Issue	Status	Comments
Hawaii Telcom Manoa Central Office 2803 Lowrey Ave.	392 ft	Underground Storage Tank (UST) (500 gallon diesel)	Active, in compliance	**No impact to project at this time; reevaluate status during design phase.**
Aloha Manoa (Manoa Village Mart) 3001 E Manoa Rd.	507 ft	USTs and LUSTs, historical auto	Several tanks in use as of 009/15/2021. 4 tank closures; three with cleanup completed (2 NFA; one restrictions) and 1 with cleanup initiated.	**Reevaluate status during design phase.**
Enivel Inc. 2966 E Manoa Rd	569 ft	Historical dry cleaner (before 2000)	No longer exists; no contamination documented	No impact to project.
Manoa Mart (Manoa Liquor; former Tengan Phillips 66) 2955 E Manoa Rd	647 ft	Historical auto, UST/LUST	All tanks closed with NFA or (historical) documented out of use.	No impact to project.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Site Name and address	Distance	Program or Issue	Status	Comments
Manoa Elementary School 3155 Manoa Rd	844 ft	SHWS	Building exterior soils. Part of a DOE study of schools. No issues identified.	No impact to project.
IES Retail Manoa (former Manoa Service; Manoa Chevron Service) 2927 E Manoa Rd, Unit B	992 ft	Conditionally exempt small quantity generator (CESQG); historical auto, USTs	No current hazardous waste activity (last waste generation 2016); multiple closed tanks, 2 USTs currently in use; leaking hoist now closed (2017); one LUST with NFA	No impact to project.
Masa Gas Shack 2914 E Manoa Rd	1050 ft	Historical auto	No records; closed by 1982	No impact to project.
Safeway Store #204 2855 E Manoa Rd	1299 ft	CESQG	Active waste handler, no violations	No impact to project.
C&CH Manoa Fire Station 2850 E Manoa Rd	1365 ft	UST/LUST	One closed LUST (NFA); 1 previously closed 550 gallon diesel tank	No impact to project.
Mid Pac Petroleum (Tanabe's Service; Unocal SS No. 3923) 2809 E Manoa Rd	1667 ft	LUST, RCRA	3 closed LUSTs (2 NFA; 1 EHE); several permanently out of service UST; historical RCRA generator	No impact to project.
Manoa Valley Veterinary Clinic 2764 Woodlawn Drive (mis-listed as located at 2752 Woodlawn Drive)		AIRS	Operates a small crematory unit, which is regulated as an emissions source.	No impact to project.
2752 Woodlawn Drive	1694 ft		This address is a strip mall with multiple businesses listed for various programs. Each individual business is described separately, below.	
Globeteck Group 2752 Woodlawn Dr, Suite 5-204A		LEAD	Globeteck Group is an environmental consulting firm that conducts lead based paint training activities	No impact to project.
KZOO Radio Station Polynesian Studio		Historical auto	No known issues	No impact to project.
Manoa Marketplace (YY Varsity Bakery), 2752 Woodlawn Dr, Suite 5-207		UST	Permanently out of use	No impact to project.
Fendu Boulangerie (Bakery), 2752 Woodlawn Dr, Suite 5-119		FINDS/OSHA	Listed for OSHA investigation	No impact to project.
Cherrywood-Manoa 2752 Woodlawn Dr. Building 5		historical dry cleaner	No known issues	No impact to project.
Longs Drug Store #116 2750 Woodlawn Drive	1750 ft	FTTS, historical FTTS, RCRA, FIFRA	CEVSQG (last waste in 2021), historical LQG and SQG, no violations, historical investigation for pesticide issues (no issues noted)	No impact to project.
USDA ARS (Hawaii Dept of Agriculture Tropical Fruit and Vegetable) 2727 Woodlawn Dr	1804 ft	RCRA, ECHO, FINDS, SPILLS	Historic SQG (1997), undetermined spill	No impact to project.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Site Name and address	Distance	Program or Issue	Status	Comments
Shell Service Station (Tenney's Manoa Shell) 2740 E Manoa Rd	1808 ft	UST/LUST, RCRA	1 closed LUST (NFA), 4 permanently closed UST, 1 reported antifreeze spill, historical RCRA generator	Property is now a restaurant. Due to distance and status of tanks, no impact to project.
University of Hawaii at Manoa 2721 Woodlawn Dr	1900 ft	AIRS	Pathological waste incinerator, permit ended in 2016	No impact to project.
Magoon Agricultural Research Facility 2717 Woodlawn Dr	1926 ft	RCRA, FINDS, ECHO	CESQG, last activity in 2007 (pesticide and related wastes), former LQG, former violations in compliance since 2000.	Due to distance and limited nature of issues, no impact to project.
VCA University Animal Hospital 2728 Woodlawn Dr	1916 ft	MLTS	Facility holds a license for nuclear materials (presumably for diagnostic testing)	No impact to project.
Manoa Public Library 2716 Woodlawn Dr	2062 ft	FINDS, ECHO, SPILLS	Spill of an infectious waste container, listed as a minor NPDES violation for unpermitted discharges (in compliance as of 2022)	Localized incidents. No impact to project.
Noelani Elementary School 2655 Woodlawn Dr	2375 ft	SHWS	Building exterior soils. Part of a DOE study of schools. No issues identified.	No impact to project.
University of Hawaii Institute for Astronomy 2680 Woodlawn Dr	2375 ft	RCRA	CESQG, no violations, last generation 2019	Appears to be laboratory related wastes. No impact to proposed project.
Manoa Hillside Estates Kalawao St	2291 ft	FINDS, NPDES, ECHO	Terminated discharge permit	Appears to be a former permitted water discharge location. No impact to proposed project.

Two potential sites of concern within 500 ft of the project were identified: Hawaii Telcom Manoa at 2803 Lowrey Ave and Aloha Manoa at 3001 E Manoa Rd. Both of these sites have active underground storage tank use and/or former leaking underground storage tanks. Although it does not appear that these businesses have impacted the future detention basin location, re-evaluation of the site conditions at the time of design is warranted since the proposed project would include significant excavation. Due to the depth and extent of excavation for construction of a detention basin, it is recommended that the status of the detention basin site be reviewed during design phase. Soil re-use could require testing to ensure that the soils are suitable; soil re-use requirements were not evaluated here but should be considered during design.

8.2.3. The Ala Wai Golf Course Detention Basin

The Ala Wai Golf Course detention basin is a component of all three alternatives, however there are differences in alignment and configuration between the alternatives. Conservatively, it is assumed that the entire golf course footprint would be used for the selected plan, with earthwork and excavation required across the golf course and (mostly) at numerous perimeter locations

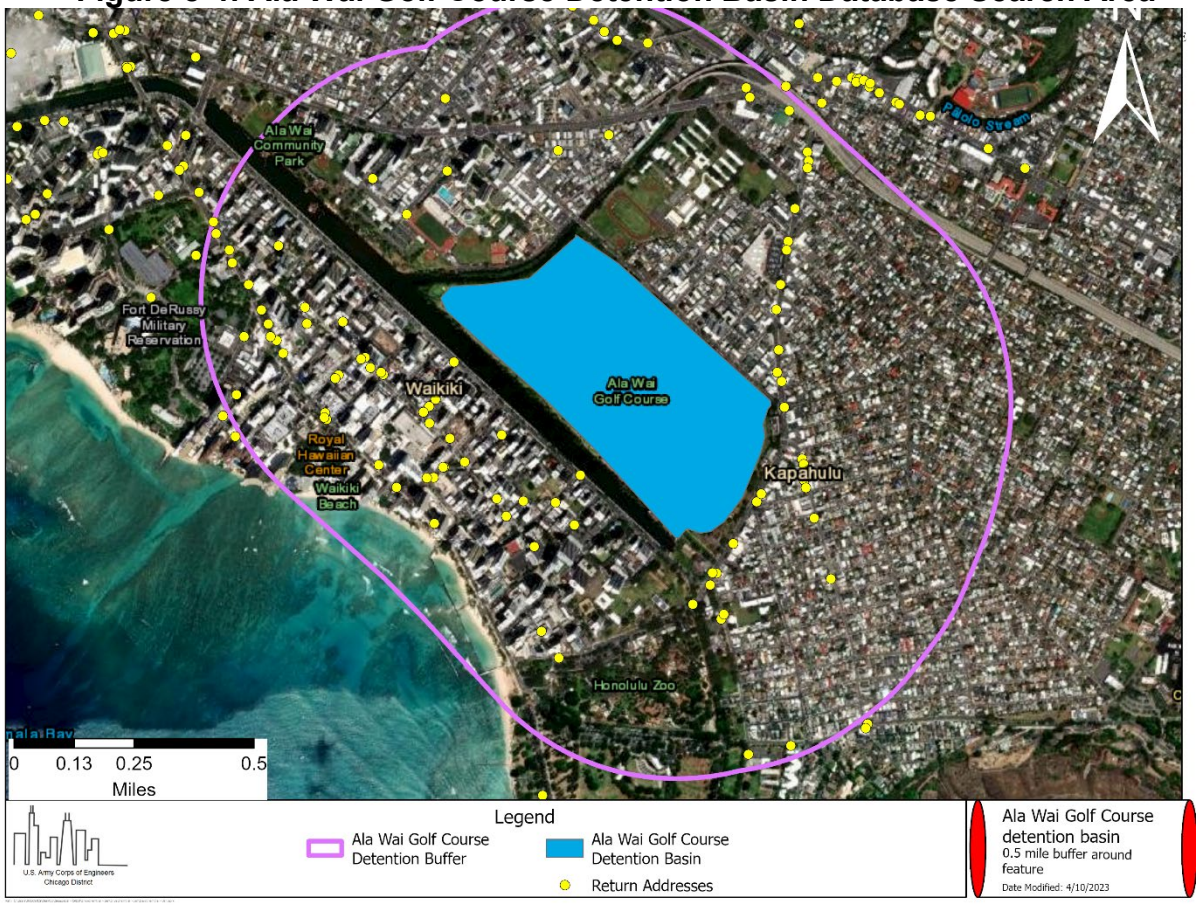
CONTROLLED UNCLASSIFIED INFORMATION (CUI)

(for drainage); the actual detention basin would be constructed by building a berm surrounding the site as opposed to excavating the golf course.

A previous investigation of conditions at the Ala Wai Golf Course (EA, 2019) indicates several RECs and data gaps associated with the site. An apparently abandoned oil-water separator exists adjacent to the maintenance buildings; the condition and status of the facility require confirmation. Equipment storage areas (unpaved and paved) have stained soils and may have existing contamination. Several USTs were removed from the site in the 1990's; monitoring wells were installed in several locations. Although soil contamination issues associated with the UST removals appear to have been addressed, the unmaintained monitoring wells represent a data gap in the groundwater condition documentation. And finally, the site has been used as a golf course since at least the late 1940's; over that time, various fertilizers and pesticides have been applied to the property. The current soil conditions are unknown.

The golf course is bounded on the northwest and southwest by the Ala Wai Drainage Canal and Manoa-Palolo Canal. Sites across the canal are hydraulically isolated from the golf course and are unlikely to impact the proposed project property; these sites are not considered further. Sites within approximately ½ mile of the golf course and on the east side are shown in Figure 8-4. The database returns for sites within ½ mile are listed in Table 8-4.

Figure 8-4: Ala Wai Golf Course Detention Basin Database Search Area



CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Table 8-4: Ala Wai Golf Course Detention Basin Database Returns

Site Name and address	Distance	Program or Issue	Status	Comments
Ala Wai Field (Ala Wai Airport)	0 ft	FUDS, SHWS	This site is located on the current Ala Wai Golf Course. The Ala Wia (Air) field was apparently used as an emergency landing strip during WWII. An earthen (turf) landing strip was prepared on the existing golf course property; it is unclear whether it was used. There are no wastes or site impacts related military use of the site.	No impact to project.
Ala Wai Golf Course 484 Kapahulu Ave	0 ft	LUST, UST	LUST cleanup complete, 3 UST permanently out of service.	**This site (the maintenance yard) is also listed as 404 Kapahulu Ave. The site is on the southeast side of the golf course and is adjacent to the Ala Wai Canal. Due to the project proximity, it should be reviewed during design phase.**
Ala Wai Golf Course Maintenance Yard 404 Kapahulu Ave	400 ft	SHWS, UST, RCRA	1 UST currently in use, CESQG	**See above listing. The maintenance yard is also listed as 484 Kapahulu Ave.**
BWS Kaimuki Pump Station 2951 Harding Ave	2543 ft	SHWS, SPILLS	UST closure, no further action.	No Impact to project.
IES Retail (Kapiolani Texaco 91919, Sunrise Service Station) 2969 S King Street.	2318 ft	RCRA, UST, historical auto	CESQG (no violations), multiple UST in use (gasohol, diesel, used oil)	No Impact to project.
Pacific Laundromat & Service 2919 Kapiolani Blvd	2173 ft	Historic cleaner	Former dry cleaning establishment	No Impact to project.
Davenroye Dry Cleaners 1042 Kapahulu Ave	2386 ft	SHWS, LUST, UST, RCRA	LUST cleanup complete with EHE/EHMP, multiple UST permanently out of service, not a generator	No Impact to project.
Longs Drug Store #10851 1029 Kapahulu Ave, Suite 303	2394 ft	RCRA	CESQG (no violations)	No Impact to project.
AIM Kapahulu 1001 Kapahulu Ave	1976 ft	LUST, UST	LUST cleanup completed with EHE/EHMP, 2 UST in use, multiple UST permanently closed	No Impact to project.
Service Cleaners 936 Kapahulu Ave	1728 ft	SHWS	Former dry cleaners.	No Impact to project.
Safeway Inc (formerly Dunkin Doughnuts) 900 Kapahulu Ave	1365 ft	RCRA, LUST, UST	Historic generator, LLUST cleanup complete, multiple UST permanently out of use	No Impact to project.
Safeway Store #2747 888 Kapahulu Ave	1285 ft	RCRA	CESQG (no violations)	No Impact to project.
Manoa-Palolo Drainage Canal at Moiliili	0 ft		This database listing has no information available.	The canal itself is part of the project and conditions in the canal

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Site Name and address	Distance	Program or Issue	Status	Comments
				will be considered during design.
Loves Bakery 836 Kapahulu Ave	1176 ft	SHWS, LUST, UST	LUST cleanup complete, multiple UST permanently out of use since 1981	No impact to project.
Kuhio Cleaners 810 Kapahulu Ave	849 ft	UST	UST permanently out of service since 1991	No impact to project.
Winam Shell Service (Goose's Edge, Inc, Winam Auto Service) 755 Kapahulu Ave	591 ft	RCRA, LUST, UST, AIRS, Historic Auto	Historic generator, historic auto service, multiple LUST cleanup complete, multiple UST all permanently out of service by 2010, former air permit for soil vapor extraction system expired in 2000	Area is currently an open field. No impact to project.
Kapahulu Pumping Station	851 ft	FUDS	Unclear history; the land was apparently acquired by GSA in 1967. The site is considered closed and no remediation activities are planned. The plotted database site is a residential neighborhood.	No impact to project.
Eldon Drapery Cleaner 716 Kapahulu Ave	225 ft	Historic Cleaner	No additional documentation available. Site is now a store.	No impact to project.
Tesoro Hawaii Corporation (Hele Kapahulu #61013, Pacific Resources Inc) 707 Kapahulu Ave	291 ft	Historic Auto, LUST, UST	Historic service station (and operating gas station), LUST cleanup complete, 3 UST in use (gasohol and diesel), several UST permanently out of use	No impact to project.
Diamond Service, Inc 629 Kapahulu Ave	192 ft	Historic Auto	Historic service station	No impact to project.
RRR Recycling – Kapahulu Ave 548 Kapahulu Ave	142 ft	SWRCY	Solid waste recycling collection point (paper, non-ferrous scrap)	No impact to project.
Campbell Clothes Cleaners 3306 Campbell Ave	484 ft	Historic cleaner	Historic dry cleaner prior to 1971. Property is now used by a roofing company.	No impact to project.
Island Triathlon & Bike, Inc 3312 Campbell Ave	516 ft	RCRA	Not a waste generator verified by inspection in 1995.	No impact to project.
Aloha Campbell 3327 Campbell Ave	504 ft	LUST, UST, SPILLS	LUST clean up complete, 3 UST in use (gasohol, diesel) and several permanently out of use, reported transformer release	**No impact to project, however due to proximity to the project, re-evaluate during design.**
Campbell Avenue Service Station (Mal Mat Auto Leasing, JH Sakamoto & Associates) 3335 Campbell Ave	582 ft	Historic Auto, RCRA, UST	Historic service station, former waste handler (no violations), 3 UST permanently out of service in 1992. Now a car audio shop.	**No impact to project, however due to proximity to the project, re-evaluate during design.**
Kim Chau Launderette 517 Kapahulu Ave	207 ft	UST	1 UST permanently out of service since 1992.	**No impact to project, however due to proximity to the project, re-evaluate during design.**
Georges Union Service (Unocal 76 SS L 4573, George's Union Service	198 ft	Historic Auto, RCRA, SHWS, LUST, UST	Historic service station, historic waste generator, residual petroleum hydrocarbons in former hoist	**No impact to project, however due to proximity to the**

#4573, 76 Kapahulu 7-11 #116) 505 Kapahulu Ave			area. LUST cleanup complete, 2 UST in use (gasohol), multiple UST permanently out of service.	**project, re-evaluate during design.**
Green Thumb Incorporated 3363 Campbell Ave	777 ft	UST	2 UST permanently out of service in 1998.	No impact to project.
Dorothy Tanaka 3423 Campbell Ave	1344 ft	UST	1 UST permanently out of service in 1985.	No impact to project.
Tonys Auto Service Ltd 449 Kapahulu Ave	269 ft	Historic Auto, Historic Cleaner	Historic service station and dry cleaner; the property is now occupied by a multistory building that appears more recent than the service station (closed in 80's) and cleaners (closed in 90's)	**No impact to project, however due to proximity to the project, re-evaluate during design.**
Ala Wai Service Inc (Ala Wai Boat Harbor Slot 61 & 62) 407 Kapahulu Ave	523 ft	SHWS, SPILLS, LUST, UST, historic auto, RCRA	LUST cleanup complete, 3 UST in use (gasohol) and multiple UST permanently closed, CESQG	**No impact to project, however due to proximity to the project, re-evaluate during design.**
BKM Enterprises LTD. VS. Elsie Tome, DPB Tsuru Ka Kapahulu Ave	678 ft	SPILLS	No information available.	**No impact to project, however due to proximity to the project, re-evaluate during design.**
Waikiki Fire Station #7 381 Kapahulu Ave	726 ft	SPILLS, UST	Several UST in service and permanently out of service. No information available on the reported spill.	**No impact to project, however due to proximity to the project, re-evaluate during design.**
Kapiolani Regional Park Service Center 3447 Leahi Ave	764 ft	LUST, UST, RCRA	LUST cleanup complete, UST permanently out of service. CESQG, historic generator, no violations.	No impact to project.
Hawaii School for the Deaf and Blind	863 ft	SHWS	Building exterior soils. Part of a DOE study of schools. Low concentration of lead found at one location, considered a low risk and below action levels.	No impact to project.
Jefferson Elementary School 324 Kapahulu Ave	1097 ft	SHWS	Building exterior soils. Part of a DOE study of schools. No issues identified.	No impact to project.
Base Yard No 16 & 17	1483 ft	FUDS	The site was used to store office supplies (Yard 16) and refrigeration equipment and steel (Yard 17) during WWII. The site is now part of the Honolulu Zoo and a parking lot. There are no environmental issues associated with the site.	No impact to project.
Heco Transformer V8425 151 Kapahulu Ave	1872 ft	SHWS	A release from a (non-PCB) transformer was reported; the site was addressed and received an NFA letter.	No impact to project.

The Ala Wai Golf Course was apparently used by the military as an emergency landing strip during WWII. There is no record of impacts to the site due to military use.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

A number of businesses including service stations, dry cleaners or former service stations are located along Kapahulu Avenue, which runs along the southeast side of the golf course. Although these sites do not currently have issues, due to the on-going presence of underground storage tanks and the proximity to the proposed detention basin, it is recommended that these sites be reviewed during design phase.

The Ala Wai Golf Course maintenance yard is located along Kapahulu Ave on the southwest side of the golf course. A former LUST was remediated and USTs were taken out of service. Depending on the final alignment, the maintenance yard area could be within the project footprint; the site should be reviewed at the time of design. The Ala Wai Golf Course itself has a history of fertilizer and pesticide use. It is recommended that a Phase II investigation be conducted on any areas that would be excavated during project construction, to determine the appropriate disposition of excess soils.

8.2.4. The Kaimuki High School Berm/Floodwall

The Kaimuki High School berm and floodwall is included in all three alternatives under consideration, but there are differences in the alignment and construction. The floodwall includes sections of sheetpile wall as well as floodwall with piles, and ties into berms in some configurations. For the purposes of this evaluation, the Alternative 1 alignment (the longest option) is used as the assumed location. Sites within approximately ½ mile of the feature are shown in Figure 8-5. Table 8-5 lists the database returns within ½ mile of the Kaimuki High School Berm/Floodwall. Only sites south of Palolo Stream and southeast of the Ala Wai Canal are included in the table. Due to the presence of the stream and canal, sites on the other side are hydraulically isolated from the proposed berm/floodwall and are unlikely to represent a source of contamination for the project area.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Manoa-Palolo Drainage Canal at Moiliili			This database listing has no information available.	The canal itself is part of the project and conditions in the canal will be considered during design.
Loves Bakery 836 Kapahulu Ave	1330 ft	SHWS, LUST, UST	LUST cleanup complete, multiple UST permanently out of use since 1981	No impact to project.
Kuhio Cleaners 810 Kapahulu Ave	1432 ft	UST	UST permanently out of service since 1991	No impact to project.
Winam Shell Service (Goose's Edge, Inc, Winam Auto Service) 755 Kapahulu Ave	1713 ft	RCRA, LUST, UST, AIRS, Historic Auto	Historic generator, historic auto service, multiple LUST cleanup complete, multiple UST all permanently out of service by 2010, former air permit for soil vapor extraction system expired in 2000	Area is currently an open field. No impact to project.
Kapahulu Pumping Station	1789 ft	FUDS	Unclear history; the land was apparently acquired by GSA in 1967. The site is considered closed and no remediation activities are planned. The plotted database site is a residential neighborhood.	No impact to project.
Eldon Drapery Cleaner 716 Kapahulu Ave	2029 ft	Historic Cleaner	No additional documentation available. Site is now a store.	No impact to project.
Tesoro Hawaii Corporation (Hele Kapahulu #61013, Pacific Resources Inc) 707 Kapahulu Ave	2123 ft	Historic Auto, LUST, UST	Historic service station (and operating gas station), LUST cleanup complete, 3 UST in use (gasohol and diesel), several UST permanently out of use	No impact to project.
Diamond Service, Inc 629 Kapahulu Ave	2420 ft	Historic Auto	Historic service station	No impact to project.
Ala Wai Field (Ala Wai Airport)	1451	FUDS, SHWS	This site is located on the current Ala Wai Golf Course. The Ala Wia (Air) field was apparently used as an emergency landing strip during WWII. An earthen (turf) landing strip was prepared on the existing golf course property; it is unclear whether it was used. There are no wastes or site impacts related military use of the site.	No impact to project.

Although multiple potentially impacted sites were identified, there do not appear to be any potential impacts to the proposed project footprint. Due to the urban nature of the site, it is recommended that the area be reviewed during design phase to confirm that there are no potential impacts.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

8.2.5. The Kanaha Floodwall

The Kanaha Stream flows through an urban area; the Kanaha Floodwall alignment is proposed to be an approximately 2200 ft long L-wall that runs between properties in this commercial area. Sites within approximately ½ mile of the feature are shown in Figure 8-6. Table 8-6 lists the database returns within approximately ½ mile of the alignment.

Kaahumanu Elementary School 1141 Kinau St	2283 ft	SHWS	Building exterior soils. Part of a DOE study of schools. No issues identified.	No impact to project.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

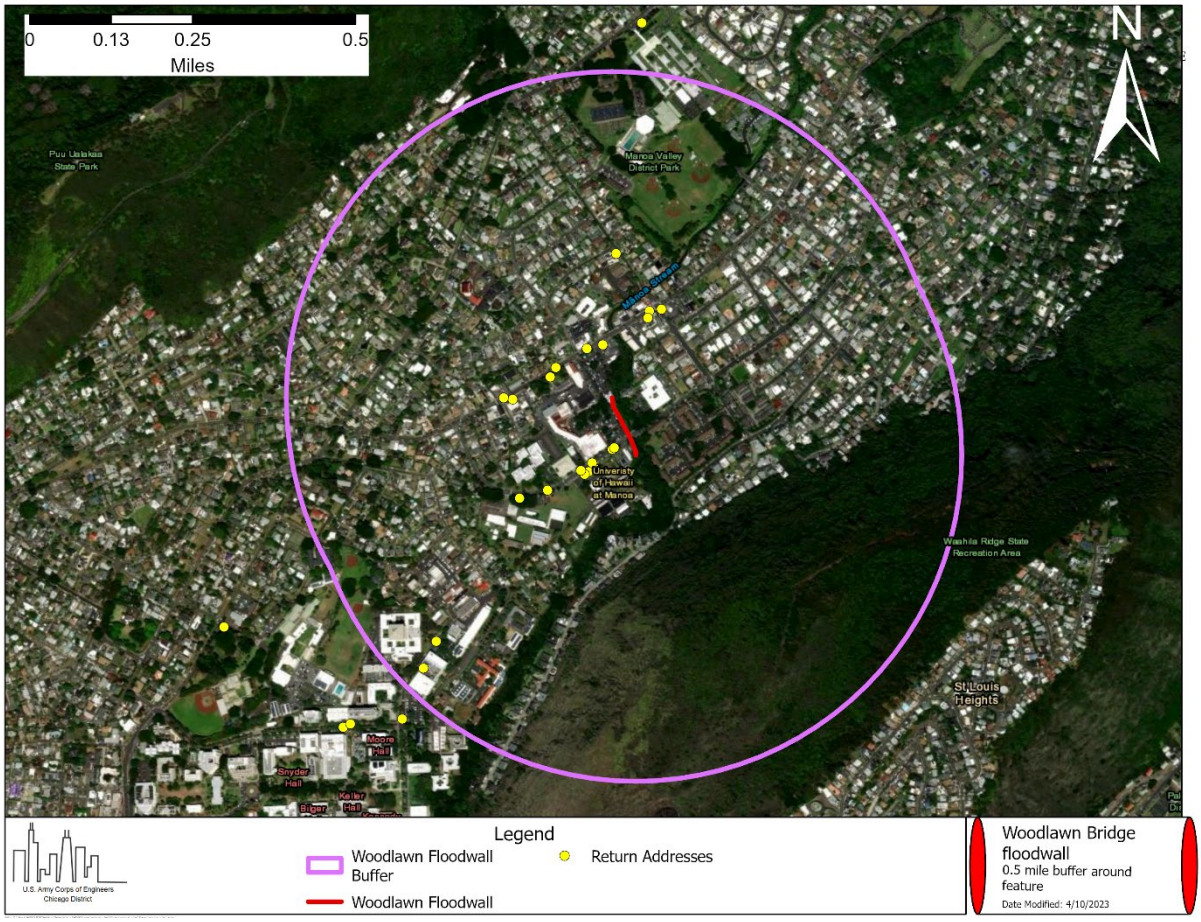
Site Name and address	Distance	Program or Issue	Status	Comments
1310 Pensacola St	2410 ft	SHWS	UST closure; residual contaminants left on site below pavement and buildings.	No impact to project.

One potential impact to the project, a former paint spill location, was identified within the limits of the proposed project. Although no additional details on the size and nature of the spill were found, the paint spill appears to be an isolated issue. It occurred many years ago. It is recommended that the site be re-evaluated during design, to determine if there do appear to be impacts from the spill.

8.2.6. The Woodlawn Drive Floodwall

The Manoa Stream meanders along a residential area. The Woodlawn Drive Floodwall would be constructed along the stream, downstream of Woodlawn Drive. The land immediately adjacent to the stream is undeveloped (a corridor approximately 150 feet wide). Sites within approximately ½ mile of the feature are shown in Figure 8-7. Table 8-7 gives a summary of database returns within approximately ½ mile of the proposed floodwall alignment.

Figure 8-7: Woodlawn Drive Floodwall Database Search Area



CONTROLLED UNCLASSIFIED INFORMATION (CUI)

USDA ARS (Hawaii Dept of Agriculture Tropical Fruit and Vegetable) 2727 Woodlawn Dr	217 ft	RCRA, ECHO, FINDS, SPILLS	Historic SQG (1997), undetermined spill	No impact to project.
Shell Service Station (Tenney's Manoa Shell) 2740 E Manoa Rd	1125 ft	UST/LUST, RCRA	1 closed LUST (NFA), 4 permanently closed UST, 1 reported antifreeze spill, historical RCRA generator	Property is now a restaurant. Due to distance and status of tanks, no impact to project.
University of Hawaii at Manoa 2721 Woodlawn Dr	246 ft	AIRS	Pathological waste incinerator, permit ended in 2016	No impact to project.
Magoon Agricultural Research Facility 2717 Woodlawn Dr	267 ft	RCRA, FINDS, ECHO	CESQG, last activity in 2007 (pesticide and related wastes), former LQG, former violations in compliance since 2000.	Due to distance and limited nature of issues, no impact to project.
VCA University Animal Hospital 2728 Woodlawn Dr	421 ft	MLTS	Facility holds a license for nuclear materials (presumably for diagnostic testing)	No impact to project.
Manoa Public Library 2716 Woodlawn Dr	503 ft	FINDS, ECHO, SPILLS	Spill of an infectious waste container, listed as a minor NPDES violation for unpermitted discharges (in compliance as of 2022)	Localized incidents. No impact to project.
Noelani Elementary School 2655 Woodlawn Dr	936 ft	SHWS	Building exterior soils. Part of a DOE study of schools. No issues identified.	No impact to project.
University of Hawaii Institute for Astronomy 2680 Woodlawn Dr	937 ft	RCRA	CESQG, no violations, last generation 2019	Appears to be laboratory related wastes. No impact to proposed project.
Manoa Hillside Estates Kalawao St	50 ft	FINDS, NPDES, ECHO	Terminated discharge permit	Appears to be a former permitted water discharge location. No impact to proposed project.
UH Manoa Facilities Management Shop 2002 East-West Rd	1795 ft	SHWS, SPILLS	Spill of 25 gallons of oil in 2010	Localized incident. No impact to project.
UH Motor Pool 2027 East West Rd	1864 ft	LUST, UST	One LUST closed in 2001, several UST permanently closed in 1998	No impact to project.
UH Manoa Bilger Addition Compressor Room 2040 East West Rd	1870 ft	SHWS	Oil spill (<1 gallon) within building. Spill was contained and issue was closed.	No impact to project.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Site Name and address	Distance	Program or Issue	Status	Comments
Mid Pacific Institute 2445 Kaala St	2557 ft	SHWS, LUST, UST,	One LUST closed in 1999, UST permanently closed in 1998	No impact to project.

Two sites of potential concern for the Makiki District Park detention basin are also within ½ mile of the Woodlawn Drive floodwall: Hawaii Telcom Manoa at 2803 Lowrey Ave and Aloha Manoa at 3001 E Manoa Rd. Both of these sites have active underground storage tank use and/or former leaking underground storage tanks. These businesses are farther away from the Woodlawn Drive floodwall, and would be less likely to impact the proposed project. Since it is already recommended that these sites be re-evaluated at the time of design for impacts to the proposed detention basin, the potential impact to the floodwall could also be considered.

8.2.7. The Koali Road Floodwall

The Koali Road floodwall is a proposed approximately 2500 ft L-wall on micropiles, running along Koali Road and Palolo Stream. The northern end of the wall would be within the Kãnewai Community Park. The remainder of the land use is predominantly residential. Many sites are physically separated from the proposed floodwall area by the Manoa Stream; due to hydraulic separation, those sites are unlikely to impact the proposed project area and were not evaluated further. Sites within approximately ½ mile of the feature are shown in Figure 8-8. Database returns are listed in Table 8-8.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Hawaiian Humane Society 2700 Waialae Ave	1337 ft	UST	UST permanently out of use since 1989.	No impact to project.
UH Manoa Frear Hall Construction Project 2569 Dole St	1591 ft	SHWS	Chlordane found in soils; contaminated material removed during construction.	No impact to project.
Barbers Point Naval Air Station, 21.296188/-157.813873	1170 ft		Appears to be mis-plotted	No impact to project.
NOAA – Honolulu Laboratory 2570 Dole St	1054 ft	LUST, UST	LUST cleanup complete, 2 small UST permanently out of service since 1997	No impact to project.
UH Kennedy Theater 1770 East-West Rd	2282 ft	SHWS, SPILLS	Oil leak (hydraulic oil), low priority brownfield site.	No impact to project.
UH Manoa Henke Hall 1800 East-West Rd	2484 ft	SHWS	Controls required to manage contamination; chlordane in soils encountered during construction.	No impact to project.
UH Manoa Lower Campus Tennis Courts 2693 Dole St	579 ft	SHWS	Soil contamination due to a leaking transformer; remediation complete.	No impact to project.
Manoa Str at Kanewai Field	45 ft	PFAS WQP	Kanewai Field is a park bordered on the north by Manoa Stream. Manoa Stream has been the focus of environmental monitoring (water chemistry, sediment chemistry, biota). Manoa Stream is on Hawaii's 303d list of impaired waters.	No impact to project.
Saint Louis College Hospital	992 ft	FUDS	The site was used by the military as a hospital during World War II. The site is now used as a school. Four USTs installed by the Army were removed by the school in 1990. There is no further action identified for the property.	No Impact to project.
Hokulani Elementary School 2940 Kamakini St	169 ft	SHWS	Building exterior soils. Part of a DOE study of schools. No issues identified.	No Impact to project.
St Louis College (Kalaepohaku)	2008 ft	SHWS	FUDS. Part of the St. Louis College Hospital site.	No Impact to project.

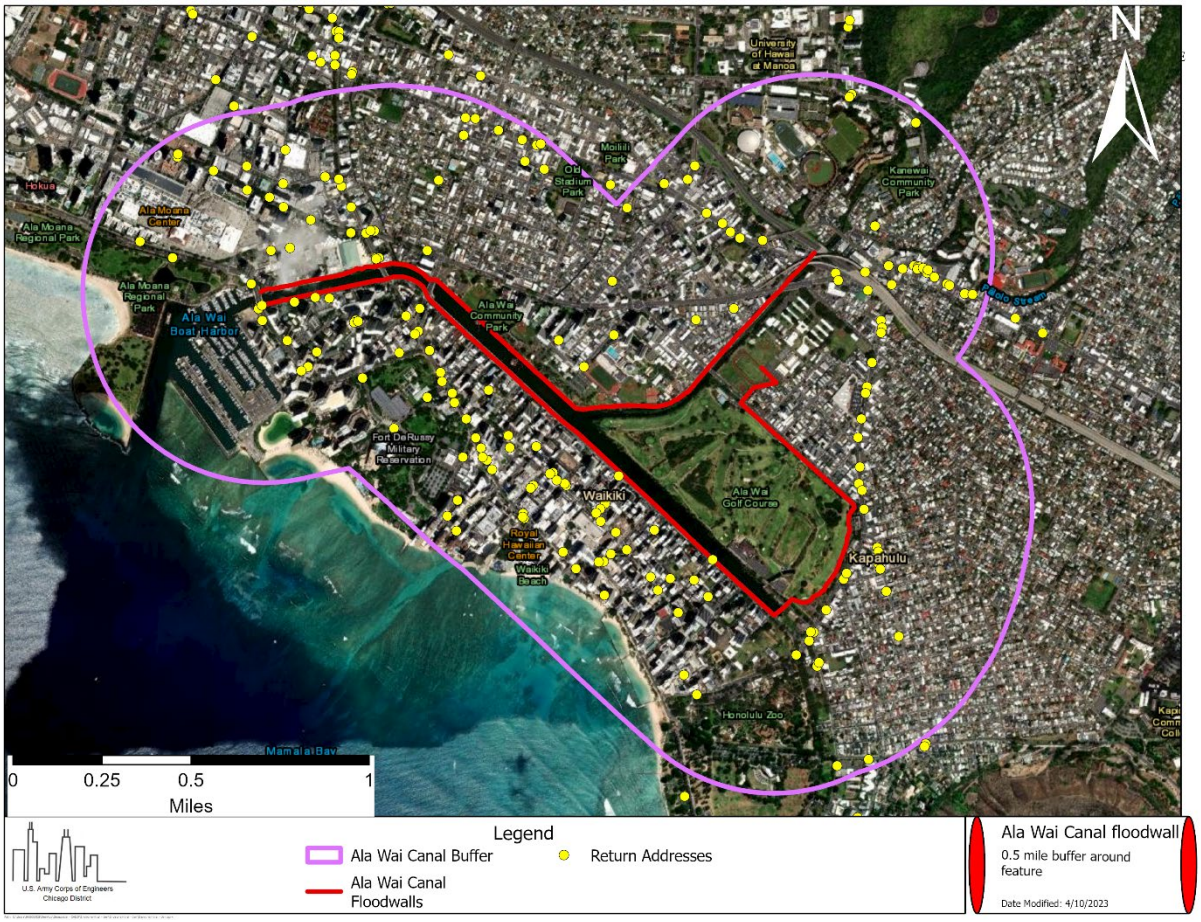
Although multiple potentially impacted sites were identified, there do not appear to be any potential impacts to the proposed project site. Due to the urban nature of the site, it is recommended that the area be reviewed during design phase to confirm that there are no potential impacts.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

8.2.8. The Ala Wai Canal Floodwall

The Ala Wai Canal floodwall is included in both the Conveyance Alternative and the Hybrid Alternative. The alignment and proposed design differ between the two alternatives, but in both cases the proposal is for a wall up to 6' high to be constructed along the length of the canal (at the edge of the canal). The wall is on both sides of the canal and would tie into the Ala Wai Golf Course berm and/or the Kaimuki High School berm or floodwall. The total length of the wall would be approximately 24,000 – 25,000 ft. A number of drainage structures would also be constructed. Because floodwall is proposed for both sides of the canal, database returns within approximately ½ mile of either side of the canal, and for the length of the canal from Highway H-1 to Ala Moana Avenue, including the stretch of canal along the Ala Wai Boulevard, were considered for impacts. The database returns are summarized in Table 8-9. Sites within approximately ½ mile of the feature are shown in Figure 8-9.

Figure 8-9: Ala Wai Canal Floodwall Database Search Area



CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Table 8-9: Ala Wai Canal Floodwall Database Returns

Site Name and address	Distance	Program or Issue	Status	Comments
AIM Kapahulu 1001 Kapahulu Ave	2311 ft	LUST, UST	LUST cleanup completed with EHE/EHMP, 2 UST in use, multiple UST permanently closed	No Impact to project.
Service Cleaners 936 Kapahulu Ave	2111 ft	SHWS	Former dry cleaners.	No Impact to project.
Safeway Inc (formerly Dunkin Doughnuts) 900 Kapahulu Ave	1737 ft	RCRA, LUST, UST	Historic generator, LLUST cleanup complete, multiple UST permanently out of use	No Impact to project.
Safeway Store #2747 888 Kapahulu Ave	1600 ft	RCRA	CESQG (no violations)	No Impact to project.
Manoa-Palolo Drainage Canal at Moiliili	0 ft		This database listing has no information available.	The canal itself is part of the project and conditions in the canal will be considered during design.
Loves Bakery 836 Kapahulu Ave	1428 ft	SHWS, LUST, UST	LUST cleanup complete, multiple UST permanently out of service	No Impact to project.
Kuhio Cleaners 810 Kapahulu Ave	1068 ft	UST	One UST permanently out of service in 1991	No impact to project.
Kapahulu Pumping Station	899 ft	FUDS	Unclear history; the land was apparently acquired by GSA in 1967. The site is considered closed and no remediation activities are planned. The plotted database site is a residential neighborhood.	No impact to project.
Winam Shell Service (Goose's Edge, Inc, Winam Auto Service) 755 Kapahulu Ave	691 ft	RCRA, LUST, UST, AIRS, Historic Auto	Historic generator, historic auto service, multiple LUST cleanup complete, multiple UST all permanently out of service by 2010, former air permit for soil vapor extraction system expired in 2000	Area is currently an open field. No impact to project.
Eldon Drapery Cleaner 716 Kapahulu Ave	246 ft	Historic Cleaner	No additional documentation available. Site is now a store.	No impact to project.
Tesoro Hawaii Corporation (Hele Kapahulu #61013, Pacific Resources Inc) 707 Kapahulu Ave	292 ft	Historic Auto, LUST, UST	Historic service station (and operating gas station), LUST cleanup complete, 3 UST in use (gasohol and diesel), several UST permanently out of use	No impact to project.
Diamond Service, Inc 629 Kapahulu Ave	196 ft	Historic Auto	Historic service station	No impact to project.
Ala Wai Field (Ala Wai Airport)	0 ft	FUDS, SHWS	This site is located on the current Ala Wai Golf Course. The Ala Wia (Air) field was apparently used as an emergency landing strip during WWII. An earthen (turf) landing strip was prepared on the existing golf course property; it is unclear whether it was used. There are no wastes or site impacts related military use of the site.	No impact to project.

				Wai Canal. Due to the project proximity, it should be reviewed during design phase.
Ala Wai Golf Course Maintenance Yard 404 Kapahulu Ave	400 ft	SHWS, UST, RCRA	1 UST currently in use, CESQG	**See above listing. The maintenance yard is also listed as 484 Kapahulu Ave.**
Ala Wai Service Inc (Ala Wai Boat Harbor Slot 61 & 62) 407 Kapahulu Ave	525 ft	SHWS, SPILLS, LUST, UST, historic auto, RCRA	LUST cleanup complete, 3 UST in use (gasohol) and multiple UST permanently closed, CESQG	No impact to project.
BKM Enterprises LTD. VS. Elsie Tome, DPB Tsuru Ka Kapahulu Ave	704 ft	SPILLS	No information available.	No impact to project.
Waikiki Fire Station #7 381 Kapahulu Ave	727 ft	SPILLS, UST	Several UST in service and permanently out of service. No information available on the reported spill.	No impact to project.
Kapiolani Regional Park Service Center 3447 Leahi Ave	862 ft	LUST, UST, RCRA	LUST cleanup complete, UST permanently out of service. CESQG, historic generator, no violations.	No impact to project.
Hawaii School for the Deaf and Blind	863 ft	SHWS	Building exterior soils. Part of a DOE study of schools. Low concentration of lead found at one location, considered a low risk and below action levels.	No impact to project.
Jefferson Elementary School 324 Kapahulu Ave	919 ft	SHWS	Building exterior soils. Part of a DOE study of schools. No issues identified.	No impact to project.
Base Yard No 16 & 17	1272 ft	FUDS	The site was used to store office supplies (Yard 16) and refrigeration equipment and steel (Yard 17) during WWII. The site is now part of the Honolulu Zoo and a parking lot. There are no environmental issues associated with the site.	No impact to project.
Heco Transformer V8425 151 Kapahulu Ave	1661 ft	SHWS	A release from a (non-PCB) transformer was reported; the site was addressed and received an NFA letter.	No impact to project.
ABC Store Underground Storage Tank Removal 2546 Lemon Rd	1458 ft	SHWS, SPILLS	UST removal and remedial activities. Cleanup is complete, NFA. Site is a convenience store.	No impact to project.
Ala Wai Blvd and Wai Nani	0 ft	ERNS	In 2017, a “thick brown substance” with “no odor” was observed on the water surface of the Ala Wai Canal. The source of the issue is unknown.	**Multiple spills are listed along and within the Ala Wai Canal. These appear transitory but may have left soil or sediment impacts. Reevaluate during design.**

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Site Name and address	Distance	Program or Issue	Status	Comments
Hawaii Amalgamated Ventures 311 Ohua St	227 ft	Historic Auto	Historic service station; the site now holds a multi-story apartment building.	No impact to project.
Prince Kuhio Hotel Report 2500 Kuhio Ave	838 ft	SHWS, AIRS	Air permit for large boilers, past release of petroleum which appears to have not been addressed.	**Reevaluate status during design.**
HECO Transformer 27266 Self Implementing PCB Cleanup 249 Liliuokalani Ave	415 ft	SHWS, SPILLS	Spill of transformer oil that contained PCBs, site has been remediated	No impact to project.
2500 Ala Wai Boulevard	0 ft	SPILLS	No data found	**Multiple spills are listed along and within the Ala Wai Canal. These appear transitory but may have left soil or sediment impacts. Reevaluate during design.**
Kuhio Village Resort AOAO 3463 Kuhio Ave	965 ft	SPILLS, RCRA	CESQG (no violations), reported spill of waste oil	No impact to project.
Waikiki Central Office 214 Kapuni St	740 ft	LUST, UST	LUST cleanup complete, UST (diesel) in use, multiple UST permanently closed	No impact to project.
Remediation Specialists 2440 Kuhio Ave Ste 1903	775 ft	RCRA	Historic waste generator	No impact to project.
Hertz Rent-a-car (area 2602-10) 2424 Kalakaua Ave	1456 ft	LUST, UST	LUST cleanup complete, UST permanently out of service	No impact to project.
Waikiki Sand Villa II 250 Kaiulani Ave	281 ft	SHWS	Low priority hazard, petroleum in groundwater, soil. An assessment in 2021 indicated that contaminant concentrations are below action levels. The site was issued an NFA.	**Due to proximity to project, reevaluate during design.**
Ala Wai Boulevard & Kanekapolei Street – Ala Wai Canal	0 ft	SPILLS	Oil Sheen (2011)	**Multiple spills are listed along and within the Ala Wai Canal. These appear transitory but may have left soil or sediment impacts. Reevaluate during design.**
ABC Store 21 2394 Kuhio Ave	702 ft	LUST, UST	LUST cleanup complete, multiple UST permanently out of use	No impact to project.
Waikiki Kuhio Collection 2370 Kuhio Ave	673 ft	SHWS	Petroleum in soil, site has NFA.	No impact to project.
Outrigger East 150 Kaiulani Ave	893 ft	RCRA, HAZNET	CESQG, historic generator (no violations), aged organic compounds	No impact to project.
Avis Ren-a-car System 148 Kaiulani Ave	1052 ft	LUST, UST	LUST cleanup complete, UST permanently out of service	No impact to project.

Tom Ishiis Union Service 2114 S King St	2603 ft	SHWS, LUST, UST	LUST cleanup complete, multiple UST permanently out of use	No impact to project.
Hale Makana O Moiliili 2139 Algaroba St (also listed at 2193 Algaroba St)	2359 ft	SHWS, Brownfields	Property is being redeveloped (as of 2022); site soils contain low concentrations of metals and pesticides.	No impact to project.
FUDS Warehouse No 3 & 4	511 ft	SHWS, FUDS	Two properties used during WWII for the storage of automotive supplies (tires). Both properties are along Kapiolani Blvd, The area now contains a number of apartment buildings. There are no issues identified for the properties.	No impact to project.
Kapiolani Boulevard 12 inch water main	0 ft	NPDES		No impact to project
Green Mill Food Manufacturer Ltd 914 Coolidge St	2542 ft	LUST, UST	LUST cleanup complete, multiple UST permanently out of use	No impact to project
Honolulu Limited 911 Hausten St	2438 ft	LUST, UST	LUST cleanup complete, multiple UST permanently out of use	No impact to project
Kyle's Service Sta. L-0995 2550 S Beretania St	2331 ft	LUST, UST	LUST cleanup complete, multiple UST permanently out of use	No impact to project
University of Hawaii Interchange, H-1 and University Avenue	2390 ft	SHWS	Lead contamination in soil, unremediated.	Due to distance, no impact to project.
Texaco Station 611000550 1119 University Avenue	2097 ft	LUST, UST, RCRA	LUST cleanup complete, numerous tanks out of use by 1996, historic waste generator	No impact to project.
Reynolds Recycling University Ave Trailer 1106 University Ave	22116 ft	SWRCY	Recycling collection point	No impact to project.
2700 South King St.	1390 ft	SHWS, ENG CONTROLS, INST CONTROL, SPILLS	Lead in soil and groundwater present under pavement, property is limited to commercial use.	No impact to project.
76 University 7-11 #168 2646 S King St	1640 ft	LUST, UST	LUST cleanup complete, 2 UST (gasohol) in use, several permanently closed UST	No impact to project.
Sherwin-Williams Store #8240 2733 S King St	1131 ft	RCRA	CESQG, ignitable waste, no violations	No impact to project.
Kuhio Elementary School 2759 S King St	889 ft	SHWS, SPILLS	Reported spill within school building of 2 mL mercury. Building exterior soils. Part of a DOE study of schools. No issues identified.	No impact to project.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

Site Name and address	Distance	Program or Issue	Status	Comments
Hawaiian Humane Society 2700 Waialae Ave	887 ft	UST	UST permanently out of use since 1989.	No impact to project.
C&CH McCully Fire Station 2425 Date St	1732 ft	LUST, UST	LUST cleanup complete, multiple UST permanently out of use	No impact to project
Ala Wai Cove Condominium Apartments 509 University Ave	583 ft	SHWS, SPILLS	Low hazard – residual soil and groundwater contamination after UST removal, unresolved.	**Due to proximity to project, reevaluate during design.**
University Avenue 12 inch water main	0 ft	NPDES	Construction discharges.	No impact to project.
Ala Wai Elementary School 503 Kamoku St	558 ft	SHWS	Building exterior soils. Part of a DOE study of schools. No issues identified.	No impact to project.
Iolani School 563 Kamoku St	0 ft	RCRA, UST, SHWS	CESQG, historic generator, multiple UST permanently out of service, high hazard with controls (petroleum in groundwater), organochlorine pesticides in soil incident resolved.	**Due to proximity to project, reevaluate during design.**
Kapiolani Village Apartments 737 Kaipuu St	669 ft	SHWS	Metals in soil and groundwater under buildings. NFA unless site is redeveloped.	No impact to project.
FUDS Base Yard N. 6 Kamoku Street	0 ft	SHWS, FUDS	A 25 acre portion of the property owned by Iolani School was used in WWII for storage of supplies, and later was designated as a plant assembly and repair yard. There are no known issues with the site.	No impact to project.
2633 Maunawai Place	0 ft	FTTS INSP	Residential property. The site was subject to a FIFRA/TSCA inspection in 2003, for undermined reasons.	**Due to proximity to project, reevaluate during design.**

Due to the urban nature of the project area and the proposed location of the Ala Wai Canal floodwall along the edge of the canal and bordering multiple roads, a number of sites near or adjacent to the proposed floodwall alignment were flagged for further investigation during future design phase. At this time, none of the sites appears to pose a specific impact to the project, however a number of locations have soil and/or groundwater contamination, or have historical spill issues. It is possible that soils in some portions of the floodwall alignment are contaminated by low concentrations of petroleum compounds, metals, pesticides or other anthropogenic compounds. If excavation is needed at specific locations, and particularly if excess soil will require disposal, a Phase II investigation may be warranted. Any investigation would need to be site specific, based on the proposed work and the nature of nearby conditions. It is not recommended that soil sampling be conducted along the entire proposed alignment of the Ala Wai Canal floodwall.

CONTROLLED UNCLASSIFIED INFORMATION (CUI)

8.2.9. In-Stream Work and Inlet and Outlet Culverts

The project features include numerous drainage structures, depending on the feature and topography. The location of these culverts would be immediately adjacent to the main feature, and as such any HTRW sites that would potentially impact the main feature could impact drainage structure construction. Because the culvert locations are within the search radius for the feature, impacts of database listed sites were not evaluated separately.

Drainage features would connect to the various streams and canals within the study area. The installation of inlets and outlets, as well as bank work adjacent to floodwalls and work within the channel to install floodwalls, may impact streams and canals and disturb existing sediment. The streams and canals are not listed as remediation sites, although some locations have identified localized impacts such as past spills. There is not a single systematic study of in-stream conditions within the watershed but based on limited available information (such as Spengler et al., 2019 and USGS, 2004), it is expected that the sediment within the waterways is impacted by human activities. Sediment may contain elevated levels of organochlorine pesticides (e.g., dieldrin, chlordane, and dichloro-dephenyl-trichloroethane [DDT]), polychlorinated biphenyls (PCBs), semivolatile organic compounds and polyaromatic hydrocarbons (PAHs) and metals (barium, cadmium, lead, tin and zinc). Based on future detailed design, it is strongly recommended that sediment sampling be conducted in areas where the project may cause sediment disturbance or where sediment removal is required. Based on sediment quality, proper (upland) disposal of any excavated sediment is likely required.

9. Summary and Recommendations

Based on a review of historical data and environmental records, there are no specific sites or issues that appear to represent an obstacle to the implementation of the project. However, the proposed work is within an urban area, and a number of RECs or sites with unresolved issues were identified in proximity to various project features. Depending on the exact alignment and on the extent of excavation, it is possible that some of the identified sites may have impacted soils or groundwater within the project footprint. In particular, the Ala Wai Golf Course has several RECs that are documented elsewhere (EA, 2019).

It is recommended that the database results be reviewed during design phase for each specific feature, to further evaluate whether there are project impacts. Impacts to excavations and to excess soils should be considered once project features are further designed. Targeted soil sampling (a Phase II investigation) is recommended for any areas requiring excavation that have identified specific impacts or potential impacts. The purpose of this sampling would be to determine if soils within the project footprint are impacted by anthropogenic compounds (pesticides, petroleum compounds, metals, etc), and to determine the proper handling for any excess soils. Similarly, sediment sampling is needed at locations where the work will involve streambed disturbance. The purpose of the sediment sampling would be to determine proper sediment disposal as well as any specific Clean Water Act compliance requirements. It is not recommended to conduct a Phase II investigation for the entire project footprint, nor for the entire footprint of any individual feature.

EDR Topographic Map Library has been searched by EDR and maps covering the target property location as provided by U.S. Army Corps of Engineers were identified for the years listed below. EDR's Historical Topo Map Report is designed to assist professionals in evaluating potential liability on a target property resulting from past activities. EDRs Historical Topo Map Report includes a search of a collection of public and private color historical topographic maps, dating back to the late 1800s.

Search Results:

EXECUTIVE SUMMARY

A search of available environmental records was conducted by Environmental Data Resources, Inc (EDR). The report was designed to assist parties seeking to meet the search requirements of EPA's Standards and Practices for All Appropriate Inquiries (40 CFR Part 312), the ASTM Standard Practice for Environmental Site Assessments (E1527-21), the ASTM Standard Practice for Environmental Site Assessments for Forestland or Rural Property (E 2247-16), the ASTM Standard Practice for Limited Environmental Due Diligence: Transaction Screen Process (E 1528-14) or custom requirements developed for the evaluation of environmental risk associated with a parcel of real estate.

Environmental Interest/Information System:
NCDB (National Compliance Data Base) supports implementation of the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA) and the Toxic Substances Control Act (TSCA). The system tracks inspections in regions and states with cooperative agreements, enforcement actions, and settlements.
RCRAInfo is a national information system that supports the Resource Conservation and Recovery Act (RCRA) program through the tracking of events and activities related to facilities that generate, transport, and treat, store, or dispose of hazardous waste. RCRAInfo allows RCRA program staff to track the notification, permit, compliance, and corrective action activities required under RCRA.

Environmental Interest/Information System:
RCRAInfo is a national information system that supports the Resource Conservation and Recovery Act (RCRA) program through the tracking of events and activities related to facilities that generate, transport, and treat, store, or dispose of hazardous waste. RCRAInfo allows RCRA program staff to track the notification, permit, compliance, and corrective action activities required under RCRA.

Environmental Interest/Information System:

US National Pollutant Discharge Elimination System (NPDES) module of the Compliance Information System (ICIS) tracks surface water permits issued under the Clean Water Act. Under NPDES, all facilities that discharge pollutants from any point source into waters of the United States are required to obtain a permit. The permit will likely contain limits on what can be discharged, impose monitoring and reporting requirements, and include other provisions to ensure that the discharge does not adversely affect water quality.

Environmental Interest/Information System:
NCDB (National Compliance Data Base) supports implementation of the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA) and the Toxic Substances Control Act (TSCA). The system tracks inspections in regions and states with cooperative agreements, enforcement actions, and settlements.
ICIS (Integrated Compliance Information System) is the Integrated Compliance Information System and provides a database that, when complete, will contain integrated Enforcement and Compliance information across most of EPA's programs. The vision for ICIS is to replace EPA's independent databases that contain Enforcement data with a single repository for that information. Currently, ICIS contains all Federal Administrative and Judicial enforcement actions. This information is maintained in ICIS by EPA in the Regional offices and it Headquarters. A future release of ICIS will replace the Permit Compliance System (PCS) which supports the NPDES and will integrate that information with Federal actions already in the system. ICIS also has the capability to track other activities occurring in the Region that support Compliance and Enforcement programs. These include; Incident Tracking, Compliance Assistance, and Compliance Monitoring.

Environmental Interest/Information System:
RCRAInfo is a national information system that supports the Resource Conservation and Recovery Act (RCRA) program through the tracking of events and activities related to facilities that generate, transport, and treat, store, or dispose of hazardous waste. RCRAInfo allows RCRA program staff to track the notification, permit, compliance, and corrective action activities required under RCRA.

Environmental Interest/Information System:
US National Pollutant Discharge Elimination System (NPDES) module of the Compliance Information System (ICIS) tracks surface water permits issued under the Clean Water Act. Under NPDES, all facilities that discharge pollutants from any point source into waters of the United States are required to obtain a permit. The permit will likely contain limits on what can be discharged, impose monitoring and reporting requirements, and include other provisions to ensure that the discharge does not adversely affect water quality.

Environmental Interest/Information System:
RCRAInfo is a national information system that supports the Resource Conservation and Recovery Act (RCRA) program through the tracking of events and activities related to facilities that generate, transport, and treat, store, or dispose of hazardous waste. RCRAInfo allows RCRA program staff to track the notification, permit, compliance, and corrective action activities required under RCRA.

Environmental Interest/Information System:
ICIS (Integrated Compliance Information System) is the Integrated Compliance Information System and provides a database that, when complete, will contain integrated Enforcement and Compliance information across most of EPA's programs. The vision for ICIS is to replace EPA's independent databases that contain Enforcement data with a single repository for that information. Currently, ICIS contains all Federal Administrative and Judicial enforcement actions. This information is maintained in ICIS by EPA in the Regional offices and it Headquarters. A future release of ICIS will replace the Permit Compliance System (PCS) which supports the NPDES and will integrate that information with Federal actions already in the system. ICIS also has the capability to track other activities occurring in the Region that support Compliance and Enforcement programs. These include; Incident Tracking, Compliance Assistance, and Compliance Monitoring.

Environmental Interest/Information System:
RCRAInfo is a national information system that supports the Resource Conservation and Recovery Act (RCRA) program through the tracking of events and activities related to facilities that generate, transport, and treat, store, or dispose of hazardous waste. RCRAInfo allows RCRA program staff to track the notification, permit, compliance, and corrective action activities required under RCRA.

Environmental Interest/Information System:
US National Pollutant Discharge Elimination System (NPDES) module of the Compliance Information System (ICIS) tracks surface water permits issued under the Clean Water Act. Under NPDES, all facilities that discharge pollutants from any point source into waters of the United States are required to obtain a permit. The permit will likely contain limits on what can be discharged, impose monitoring and reporting requirements, and include other provisions to ensure that the discharge does not adversely affect water quality.

Environmental Interest/Information System:
RCRAInfo is a national information system that supports the Resource Conservation and Recovery Act (RCRA) program through the tracking of events and activities related to facilities that generate, transport, and treat, store, or dispose of hazardous waste. RCRAInfo allows RCRA program staff to track the notification, permit, compliance, and corrective action activities required under RCRA.

Environmental Interest/Information System:
RCRAInfo is a national information system that supports the Resource Conservation and Recovery Act (RCRA) program through the tracking of events and activities related to facilities that generate, transport, and treat, store, or dispose of hazardous waste. RCRAInfo allows RCRA program staff to track the notification, permit, compliance, and corrective action activities required under RCRA.

Click this hyperlink while viewing on your computer to access additional FINDS: detail in the EDR Site Report.

Environmental Interest/Information System:
RCRAInfo is a national information system that supports the Resource Conservation and Recovery Act (RCRA) program through the tracking of events and activities related to facilities that generate, transport, and treat, store, or dispose of hazardous waste. RCRAInfo allows RCRA program staff to track the notification, permit, compliance, and corrective action activities required under RCRA.

Summary:	Removal of a hydraulic hoist on 10/25/2016. Samples taken 7.5 feet bgs and did not see evidence of petroleum contaminated soil. Analytical results indicate PAH and TPH-O below DOH EALs. Please note that the Incident Case No. assigned to the case is 20161122-1507LG and not 20161122-1057LG. Report: Hoist Removal Soil Sampling Technical Memo, Manoa Chevron Service Station, 2927 East Manoa Road, Honolulu, Hawaii, Island Energy Services Facility No. 95683, December 1, 2016, prepared by Arcadis, U.S. Inc. to Marc Dexter. The Hawaii Department of Health (HDOH), Hazard Evaluation and Emergency Response (HEER) Office has reviewed the subject document. It is unclear if the confirmation sample taken and analyzed followed the HDOH HEER s Technical Guidance Manual using multi-incremental sampling. DOH concurs with the report which documents the response actions taken as a result of the hoist removal. Please be aware that if future information indicate that contaminant exposure at the site becomes a threat to public health, the environment or natural resources, the HDOH may require additional investigation and/or cleanup work be performed.

Environmental Interest/Information System:
RCRAInfo is a national information system that supports the Resource Conservation and Recovery Act (RCRA) program through the tracking of events and activities related to facilities that generate, transport, and treat, store, or dispose of hazardous waste. RCRAInfo allows RCRA program staff to track the notification, permit, compliance, and corrective action activities required under RCRA.
STATE MASTER

Environmental Interest/Information System:

RCRAInfo is a national information system that supports the Resource Conservation and Recovery Act (RCRA) program through the tracking of events and activities related to facilities that generate, transport, and treat, store, or dispose of hazardous waste. RCRAInfo allows RCRA program staff to track the notification, permit, compliance, and corrective action activities required under RCRA.

Hazardous Waste Summary:

Waste Code:	D001
Waste Description:	IGNITABLE WASTE
Waste Code:	D002
Waste Description:	CORROSIVE WASTE
Waste Code:	D003
Waste Description:	REACTIVE WASTE
Waste Code:	D035
Waste Description:	METHYL ETHYL KETONE
Waste Code:	F001
Waste Description:	THE FOLLOWING SPENT HALOGENATED SOLVENTS USED IN DEGREASING: TETRACHLOROETHYLENE, TRICHLORETHYLENE, METHYLENE CHLORIDE, 1,1,1-TRICHLOROETHANE, CARBON TETRACHLORIDE AND CHLORINATED FLUOROCARBONS; ALL SPENT SOLVENT MIXTURES/BLENDS USED IN DEGREASING CONTAINING, BEFORE USE, A TOTAL OF TEN PERCENT OR MORE (BY VOLUME) OF ONE OR MORE OF THE ABOVE HALOGENATED SOLVENTS OR THOSE SOLVENTS LISTED

HAWAII CONVENTION CENTER (Continued) **1000277482**

IN F002, F004, AND F005; AND STILL BOTTOMS FROM THE RECOVERY OF THESE SPENT SOLVENTS AND SPENT SOLVENT MIXTURES.

Waste Code: F002
Waste Description: THE FOLLOWING SPENT HALOGENATED SOLVENTS: TETRACHLOROETHYLENE, METHYLENE CHLORIDE, TRICHLOROETHYLENE, 1,1,1-TRICHLOROETHANE, CHLOROBENZENE, 1,1,2-TRICHLORO-1,2,2-TRIFLUOROETHANE, ORTHO-DICHLOROBENZENE, TRICHLOROFLUOROMETHANE, AND 1,1,2, TRICHLOROETHANE; ALL SPENT SOLVENT MIXTURES/BLENDS CONTAINING, BEFORE USE, A TOTAL OF TEN PERCENT OR MORE (BY VOLUME) OF ONE OR MORE OF THE ABOVE HALOGENATED SOLVENTS OR THOSE SOLVENTS LISTED IN F001, F004, AND F005; AND STILL BOTTOMS FROM THE RECOVERY OF THESE SPENT SOLVENTS AND SPENT SOLVENT MIXTURES.

Waste Code: F003
Waste Description: THE FOLLOWING SPENT NONHALOGENATED SOLVENTS: XYLENE, ACETONE, ETHYL ACETATE, ETHYL BENZENE, ETHYL ETHER, METHYL ISOBUTYL KETONE, N-BUTYL ALCOHOL, CYCLOHEXANONE, AND METHANOL; ALL SPENT SOLVENT MIXTURES/BLENDS CONTAINING, BEFORE USE, ONLY THE ABOVE SPENT NONHALOGENATED SOLVENTS; AND ALL SPENT SOLVENT MIXTURES/BLENDS CONTAINING, BEFORE USE, ONE OR MORE OF THE ABOVE NONHALOGENATED SOLVENTS, AND A TOTAL OF TEN PERCENT OR MORE (BY VOLUME) OF ONE OR MORE OF THOSE SOLVENTS LISTED IN F001, F002, F004, AND F005; AND STILL BOTTOMS FROM THE RECOVERY OF THESE SPENT SOLVENTS AND SPENT SOLVENT MIXTURES.

Waste Code: F005
Waste Description: THE FOLLOWING SPENT NONHALOGENATED SOLVENTS: TOLUENE, METHYL ETHYL KETONE, CARBON DISULFIDE, ISOBUTANOL, PYRIDINE, BENZENE, 2-ETHOXYETHANOL, AND 2-NITROPROPANE; ALL SPENT SOLVENT MIXTURES/BLENDS CONTAINING, BEFORE USE, A TOTAL OF TEN PERCENT OR MORE (BY VOLUME) OF ONE OR MORE OF THE ABOVE NONHALOGENATED SOLVENTS OR THOSE SOLVENTS LISTED IN F001, F002, OR F004; AND STILL BOTTOMS FROM THE RECOVERY OF THESE SPENT SOLVENTS AND SPENT SOLVENT MIXTURES.

Environmental Interest/Information System:
RCRAInfo is a national information system that supports the Resource Conservation and Recovery Act (RCRA) program through the tracking of events and activities related to facilities that generate, transport, and treat, store, or dispose of hazardous waste. RCRAInfo allows RCRA program staff to track the notification, permit, compliance, and corrective action activities required under RCRA.
STATE MASTER
HAZARDOUS WASTE BIENNIAL REPORTER
